The determination of chloride unidirectional fluxes with chlorine-36 in short-circuited skins with normal Ringer solutions in both sides shows that the influx of this ion is considerably higher than the outflux The mean value for the net transport of chloride was 1 16 μequiv /cm^2

Table 1 ION FLUXES IN SKIN OF *Leptodactylus ocelatus* MEASURED WITH SODIUM-24 AND CHLORINE-36 OVER SUCCESSIVE PERIODS OF 30 MIN

	No of experiments	No of sampling periods	μequiv / h/cm^2 (± *S E*)	μamp/cm^2 computed from flux	μamp/cm^2 from short-circuit current
Na influx	8	53	2 44 ±0 35	65 5	42 0*
Na outflux	4	28	0 25 ±0 05	6 7	49 0
Na influx (in sulphate Ringer)	4	35	2 98 ±0 32	79 8	78 0
Cl influx	6	44	1 90 ±0 22	51 0	51 8
Cl outflux	4	29	0 74 ±0 25	19 9	44 0

* The mean difference, for paired data, between μamp computed and measured is statistically significant ($P<0\ 01$)

Furthermore, when sodium ions are substituted by choline in both sides, a reversal of the potential is observed and a short-circuit current due only to chloride transport could be determined If sodium is again added to the outside solution, the short-circuit current rapidly attains its normal direction and magnitude

In the skin of *Leptodactylus ocelatus*, the short-circuit current is equal to the algebraic sum of the current from active transport of sodium and chloride

If the values of the net transports are expressed in μamp and referred to the short-circuit current (I) then, $I = I_{Na\ net} - I_{Cl\ net}$ In four experiments in which sodium and chloride net transports were determined simultaneously a mean short-circuit current of 49 5 μamp/cm^2 compares with a difference of 41 2 μamp/cm^2 between the net transports of sodium and chloride

Active chloride transport in animal tissues has been described in intact Anurans[2], gastric mucosa[3] and the ileum of the rat[4] The isolated skin of European frogs shows chloride transport after the application of adrenaline, but this transport is in the outward direction and caused by the stimulation of skin glands[5]

This demonstration of a contribution to the short-circuit current by chloride transport in a frog skin clearly suggests that a ‘chloride pump is present in animal systems other than the digestive-tract

Brain and Muscle Potentials from the Intra-Uterine Fœtus in Unnarcotized, Conscious Animals

IN a continuation on investigations of the development of muscular activity and brain potentials in fœtal guinea pigs[1] it was observed that punctures made with thin needles of the pregnant uterus and the fœtal membranes did not cause an appreciable outflow of the amniotic fluid In cases where such an outflow

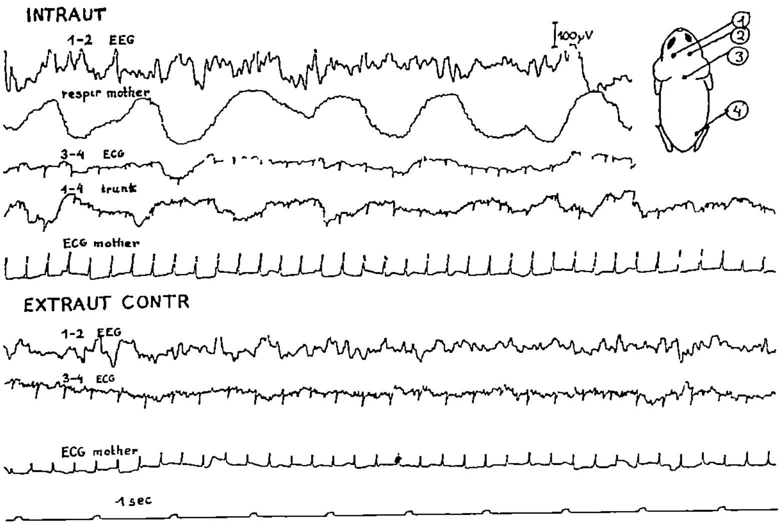

Fig 1 Recordings of the EEG and the ECG of the intra-uterine fœtus in a conscious, unnarcotized pregnant guinea pig (age of the fœtus, 50 days) The insert shows the position of the electrodes The control recording made on the same fœtus under extra-uterine conditions The μV calibration refers to EEG tracing only

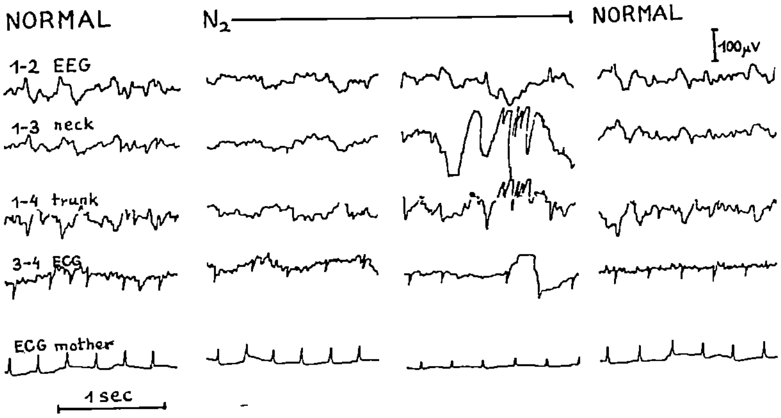

Fig 2 The effect of nitrogen breathing of the pregnant, conscious guinea pig on the EEG, ECG and muscular activity of the intra-uterine fœtus (age 60 days) The different lead numbers refer to the insert of Fig 1 The μV calibration refers to the EEG tracing only

appeared, it was soon stopped, possibly by a reaction of the membranes The experience gained in this respect led to the development of a technique which allowed of a registration of bioelectric potentials from the intra-uterine fœtus in chronic experiments with unnarcotized, conscious, pregnant animals

Pregnant guinea pigs were narcotized with 'Thiogenal' (methylthioethyl-2-pentyl-thiobarbituric acid, sodium salt, 100–150 mgm /kgm , intraperitoneal) and the uterus was exposed under sterile conditions The hook-formed steel electrodes (insulated to the bare tip) were introduced through the uterine wall, and the membranes in the desired parts of the fœtus and the flexible electrode leads were fixed by means of sutures in the abdominal wall and connected to a 6-channel electroencephalograph (Kaiser) After the experiments (observation time up to 24 hr) the recordings were controlled with the fœtus in extra-uterine conditions but in placental connexion with the mother animal

Fig 1 shows a recording made on an intra-uterine (above) guinea pig fœtus in a conscious, pregnant animal The control recording, made later on under extra-uterine conditions on the same fœtus, is seen below In this case, the fœtus was 50 days old (gestation age 65 days) as estimated from its weight[2] The electrode positions are seen in the insert with reference to the different tracings From the top can be seen the EEG of the fœtus (record 1–2), the respiration movements of the pregnant animal (electrodes in the abdominal wall near the diaphragm), the ECG of the fœtus (record 3–4), the muscular activity of the trunk of the fœtus (record 1–4, here relatively silent) and the ECG of the pregnant animal (recorded between the forelegs) In the control tracings there can be seen the EEG of the extra-uterine fœtus, the ECG of the fœtus and that of the mother The brain potentials obtained in this manner correspond to earlier findings on guinea pig fœtuses, in which the recording of the EEG followed directly on the exposure of the cortex[1]

Fig. 2 shows the result of an experiment where the mother animal was allowed to breathe nitrogen gas In this instance the fœtus was 60 days old The electrode lead numbers refer to the inset of Fig 1 The first recording on the left shows the normal state The two following recordings were taken during the period in which the mother was breathing nitrogen (3 min) The recording to the right shows the normal state of the mother and the fœtus about 5 min after the experiment It can be seen that the hypoxia caused a decrease in the amplitude of the EEG potentials of the fœtus The neck and trunk tracings show that the fœtus was in a hyperactive state at the same time as the EEG was depressed and as the ECG of the fœtus showed arrhythmia and a slowing of the heart-rate In common, it was observed that the muscular activity caused by hypoxia appeared first in the neck region of the fœtus

The results obtained by the technique reported show that it is possible to register brain and other bioelectric potentials from the intra-uterine fœtus in an unnarcotized, conscious pregnant animal The method makes possible the investigation of the development of the motor functions and certain electrical functions of the central nervous system of the animal fœtus under physiological, intra-uterine conditions It may also help in the examination of certain problems involved in obstetrics

Role of the Liver in Enteral Insufflation of Oxygen during Hypoxia in Infant Rats

IN 1916 Yllpo suggested insufflation of the intestine with oxygen as a means of resuscitation of asphyxic new-born infants Since that time this method has been used clinically, but opinions as to its value are not undivided In recent years the method has been revised experimentally Again results are not equivocal[1]

It has been shown that the oxygen saturation of the blood in the portal vein increases after enteral insufflation with oxygen in both adult and new-born animals (rabbit, rat)[2,3] Oxygen saturation in the blood of the caudal vena cava centrally to the orifice of the hepatic vein, however, is not raised[3,4] It was concluded that oxygen absorbed from the intestine is utilized by the liver It could further be demonstrated that previous administration of oxygen into the intestine increased the survival-time of new-born mammals suffering different types of hypoxia (altitude 0 1 atm , nitrogen, potassium cyanide) significantly as compared with control animals not so treated After enteral oxygen insufflation in new-born animals a resuscitating effect in the stage of clinical death due to nitrogen hypoxia was also noted

The idea was put forward that this beneficial effect of enteral oxygen insufflation is mediated by a humoral action of the liver as suggested earlier by Rein[5] Hence a rough aqueous extract of minced liver tissue was prepared from normal rats and from rats insufflated with oxygen and also from animals that died in hypoxia These extracts were given intraperitoneally to infant rats and the survival-time of these animals suffering different types of hypoxia was then tested The results (Fig 1) show that a normal liver extract slightly prolongs survival-time during hypoxia This effect is increased with an extract from livers of rats which had first been given oxygen into the intestine The extract is ineffective if obtained from infant rats which died in hypoxia The basis of this humoral effect is being analysed

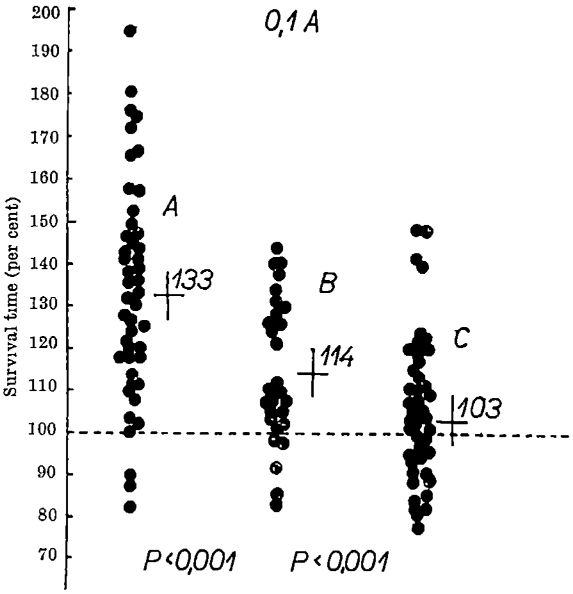

Fig 1 Changes in the survival-time in hypoxia (0 1 atm) as percentage after intraperitoneal application of a rough aqueous extract prepared from livers of rats from the same litter 100 per cent is the average survival-time of control infant rats *A*, extract from liver of animals insufflated with oxygen , *B*, the same from normal infant rats *C*, the same from infant rats that died from hypoxia

Sex and Age Differences in Post-tetanic Potentiation

POST-TETANIC potentiation has been investigated by a large number of authors in animal muscles[1], but only rarely in other structures and in man According to Peregrin[2], post-tetanic potentiation in man is in close relation to the action-rest phenomenon of Sechenov We have examined in 319 children aged 10–16 the activation of dynamic (phasic) work of the hand following static strain of 15–20 sec, the same hand working thus without rest A mercury dynamometer was used, the frequency of work being 1 contraction in 1 sec Five contractions after the static strain were statistically correlated with the last five contractions before it A statistically significant rise was observed in only half my 1,188 experiments (51 86 per cent girls, and 48 40 boys), which is markedly less than in the group of higher age studied by Peregrin

There was a clear difference between the group of 13–14 years old girls and the group of boys of the same age, thus

	Distribution in the group (per cent)	Limits for *P* 0 05 (per cent)
girls	62 83	57 29–68 37
boys	54 30	47 08–61 58

In our groups of older children only the tendency of the described direction is present A possible explanation is perhaps in connexion with earlier onset of fatigue in girls , fatigue for its part is necessary for successful activation[3,4]

Lowered Resistance to Iron in Vitamin-E Deficient Piglets and Mice

ADMINISTRATION of iron preparations to piglets is a routine procedure for prevention of anæmia It is observed that some or most of the piglets in an occasional litter may develop symptoms of acute disease and die within some hours or days after the administration The post-mortem picture is character-

Table 1 FATTY ACIDS AND VITAMIN E IN FOODS AND SOW'S MILK (MEANS OF THREE OR MORE ANALYSES)

	Fatty acids*	PFA*	Vitamin-E†
Food *A*	7 8	3 92	10 4
Food *B*	2 4	1 26	37 4
Mice food, commercial	3 9	1 87	33 5
Milk, sow 17	8 6	1 64	10 8
Milk, sow 147	11 0	1 89	13 2
Milk, sow 148	8 0	1 32	11 1

Milk, sow 54	8 3	0 84	52 2

* Percentage w/w of dry food substance and of milk, respectively
† μgm /gm dry food substance and of milk fat, respectively

ized by pericardial and pleural effusion[1], and by waxy degeneration of the skeletal musculature[2]

In our experiments, pigs of the Swedish Land Breed were used Food *A* consisted of ground grain (oats and barley, 1 1), 76 3 per cent, skim milk powder 16 8 per cent, cotton seed oil 4 6 per cent, and minerals ($CaHPO_4$ and Na_2HPO_4, 3 1) 2 3 per cent The grain and the oil were heated to 100° C for 30 hr under continuous flow of air Food *A* produced muscular dystrophy in weaned, growing pigs within 2–3 weeks Food *B* was a commercial food for sows (Table 1)

Methods for determination of vitamin E (ref 3), polyunsaturated fatty acids (PFA)[4,5], and glutamic oxaloacetic transaminase (GOT) in pigs[6] are found elsewhere The iron preparation used was an organic iron complex (IC) containing 75 mgm of Fe^{+++} per ml The dose to a piglet was 2 ml given intramuscularly.

Sows 17, 147 and 148 were given food *A* before parturition, for 6 days at the shortest and 27 days at the longest, and onwards during the lactation Their piglets showed normal growth When treated with organic iron complex at 10–27 days of age deaths occurred in all 3 litters with a mortality-rate of 9/17 (0/5 in non-treated litter mates) (One piglet was killed on the 6th day in a paralytic condition) Apathy, dyspnœa, and staggering gait were seen some hours or a day after the injection The mean survival-time in these piglets was 2 5 days

In 2 litters of sows 52 and 54, given food *B*, 7 of 11 piglets were similarly treated without any deaths or symptoms of disease In addition, we have treated 31 litters of sows given food *B* once or twice during the first 3–4 weeks of life, without any fatal results

Plasma GOT was determined before the organic iron complex injection (day 0) and afterwards at an interval of 1 or 2 days Piglets from sows 17, 147 and 148 showed a significant elevation (mean value day 0 21 7 ± 3 13, day 1 3,330 00 ± 465 31, mean difference 3,308 30 ± 465 32, $P < 0\ 001$) In surviving piglets GOT returned to normal within a week No significant rise of plasma GOT occurred in litters 52 and 54 (mean value day 0 33 40 ± 1 77, day 1 40 30 ± 5 62, mean difference 6 90 ± 5 89, $P < 0\ 3$)

Post-mortem examination showed accumulation of clear fluid in the pericardial sac and in the pleural sacs, and waxy degeneration in the body musculature

Table 2 INTRAPERITONEAL LD_{50} DOSE OF THE ORGANIC IRON COMPLEX IN MICE EACH SERIES COMPRISED 32 MICE (8 GROUPS OF 4)

Series	Diet	LD_{50}*
I	Mice, food commercial	1,800
II	Food *A*†	810
III	Food *A*†‡	> 4,000

* Mgm /kgm body-weight Calculated from summarized mortality on seventh day after injection of organic iron complex

† From 21 days before injection of organic iron complex and onwards

‡ α-Tocopheryl acetate intramuscularly twice a week, corresponding to 7 mgm /kgm body-weight per day, beginning 21 days before injection of organic iron complex

In litter 17, 2 of 4 pigs died when given the organic iron complex at 10–14 days of age (see col 1) The two surviving pigs had plasma-GOT levels of 64 and 2,500 units, respectively, on day 1 Four pigs of the litter were given α-tocopheryl acetate intramuscularly once daily for 4 consecutive days, 6 mgm /kgm body-weight, and organic iron complex on the 5th day (age 19 days) No deaths and no elevation of plasma GOT occurred (mean value day 0 31 25 ± 4 48, day 1 37 25 ± 3 97, mean difference 6 00 ± 5 92, $P < 0\ 5$)

The LD_{50} dose of the organic iron complex was determined in 3 series of albino mice, weighing about 17 gm at the time of injection of the complex (Table 2) Repeated determinations have given corresponding values

As reviewed by Golberg *et al* [7], vitamin-E destroying activity of iron in food has long been known They showed that iron overloading in rats produced changes indicating vitamin-E deficiency

Traces of iron (Fe^{+++}) accelerate the formation of lipoperoxides and the destruction of tocopherols in autoxidizing fats[8] Formation of highly reactive hydroperoxide–metal complexes was postulated The results presented here support the assumption that large amounts of iron destroy vitamin E *in vivo*

It is generally considered that vitamin E exerts an anti-oxidant effect within the cells The introduction of iron into tissues containing high amounts of PFA and low amounts of vitamin E will possibly speed up the oxidation of PFA and enhance the reactivity of the oxidation products

PHARMACOLOGY

Antibiotic Activity of Various Types of Cannabis Resin

SEVERAL methods of characterizing cannabis resin have been previously reported Thus, methods have been developed based on indophenol reaction with 2,6-dichloroquinonechlorimide[1], on a test with peroxide and sulphuric acid[2], on determining the content of the acid fraction[3] as well as on direct ultra-violet spectrophotometry[4] It has been shown in the course of this work that the differences in chemical composition shown by various types of cannabis resin may be explained by the stage of development of a phytochemical process by which cannabidiolic acid is gradually converted to cannabidiol, tetrahydrocannabinols and finally to cannabinol In previous work in this Institute this conversion process was referred to as 'ripening' of the resin Thus, cannabis in which cannabidiolic acid (the initial substance in the conversion of cannabinols) predominated was classified as 'unripe'. The resin containing mostly physiologically active tetrahydrocannabinols was referred to as 'ripe'. An 'intermediate' type of the drug contains predominantly cannabidiol, while the resin, including mostly cannabinol (the final conversion product), corresponds to the 'overripe' cannabis. An alterated type of resin, supposed to contain mostly disintegration products of cannabinols, has also been encountered. The progress of the ripening process in cannabis resin and consequently the formation of a given type was supposed to be affected by climatic, genetic and other ecological factors.

According to Krejči *et al.*[5,6] and Schultz and Haffner[7] cannabidiolic acid seems to represent the main antibiotic agent in cannabis resin. We have therefore assumed that the unripe type of cannabis, containing the largest amount of cannabidiolic acid, might exhibit the strongest antibiotic activity. Consequently it was supposed that the ripeness and the type of a drug might be roughly indicated by its antibacterial potency. No comparative data are available in the literature dealing with the antibiotic activity of various types of cannabis resin.

The purpose of the work recorded here was to examine the differences between the antibacterial potency of various types of cannabis resin and to compare the results obtained with chemical properties of corresponding samples. Eleven different samples were examined by using the diffusion method with filter paper disks, on nutrient agar medium, pH 6.0, with *B. subtilis* strain NCTC No. 8236 as test organism. The disk diameter was 12 mm and the incubation time 18 h at 37° C. A solution in penicillin G sodium in phosphate buffer of pH 6.0, in concentrations 0.5–6.0 I.U. in 1 ml., was used as standard. The dosage–response curves for ethanolic solutions of various samples were worked out in preliminary assays and accordingly the concentration of 60 mg in 1 ml was adopted for the procedure applied. The result of each assay corresponds to the calculated mean value of 10 zone diameter readings, which have been expressed in corresponding concentrations of penicillin units according to the dosage–response curve obtained simultaneously for standard preparation. As the scope of this work was not to determine the real activity of cannabis as related to penicillin, in the simplified technique adopted only one single set of tests was used, without changing the dilution in case when the readings of the inhibition zone were taken they might have been out of the reliable range. Consequently, the numerical expression of results for various samples does not necessarily correspond to a strictly quantitative relationship.

The assays were repeated on different days and the data presented correspond to the average values of several experiments. The reproducibility of results was very good. The results obtained for 11 samples examined are given in Table 1. For comparison, the type (ripeness) of the resin, as estimated by chemical methods[1–4] is also recorded.

Table 1. ANTIBIOTIC ACTIVITY AND RIPENESS OF VARIOUS SAMPLES OF CANNABIS RESIN

Sample	Antibiotic activity (I.U. of penicillin corresponding in diameter to 60 mg of resin)	Type (ripeness) by chemical methods
Germany *UN* 26	10.0	Unripe
Cyprus *UN* 32	5.60	Unripe to intermediate
Spain *UN* 45	4.12	Unripe to intermediate
Greece *UN* 1*E*	1.54	Intermediate to ripe
Greece *UN* 1*C*	0.85	Intermediate to ripe
Greece *UN* 1*F*	0.91	Ripe
Yugoslavia *KZ* 110	0.81	Ripe
Brazil *KZ* 101	0.56	Ripe
Brazil *KZ* 102	0.68	Ripe
Brazil *KZ* 103	0.54	Ripe
Canada *UN* 41	1.00	Alterated

It can be seen that the lowest values were exhibited by ripe samples from Brazil. A low potency was also shown by samples from Greece, Yugoslavia and Canada. Samples from Cyprus and Spain were much stronger, while the highest antibiotic activity was exhibited by the unripe sample from Germany, known to contain a large amount of cannabidiolic acid[3,8].

The results obtained are in good agreement with those obtained by chemical methods. To demonstrate the relationship between antibiotic activity and the content of cannabidiolic acid in cannabis resin, in Fig. 1 the results of microbiological assays have been plotted against E_{300}/E_{310} ratio as obtained by direct ultra-violet spectrophotometry. As previously reported[4], this ratio is in reverse relation to the approximate content of cannabidiolic acid in the resin examined. As seen in Fig. 1, both values appear to be correlated to each other. Only in the alterated Canadian sample, exhibiting both a low antibiotic activity and a low E_{300}/E_{310} value, may a lack of this correlation be observed. Consequently, a position on the diagram far from the line drawn might be supposed to indicate a certain alteration of phytochemical processes in the sample examined.

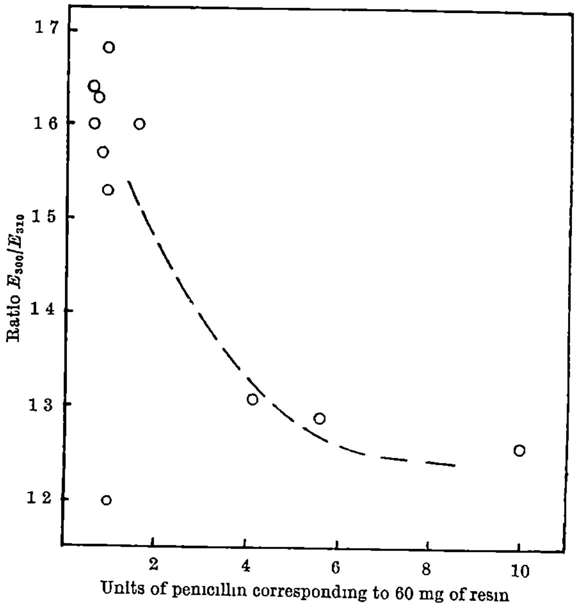

Fig. 1. Relationship of antibiotic potency and E_{300}/E_{310} value in 11 samples of cannabis resin

According to the results obtained, antibiotic activity decreases together with the progress of phytochemical conversion of cannabinols, that is, together with the increase of hashish activity. Antibacterial agent (cannabidiolic acid) is by the ripening process obviously converted into hashish-active constituents (tetrahydrocannabinols). The antibiotically active unripe cannabis seems to be more common in regions having unfavourable climate, whereas tropical samples more often correspond to the ripe, hashish-active drug. The determination of antibiotic activity may be usefully applied for the characterization of cannabis resin.

We thank the Division of Narcotic Drugs of the United Nations and Prof Décio Parreiras, Faculty of Medicine, Rio de Janeiro, for the supply of cannabis samples

Biliary Excretion of some Azo Dyes related to Tartrazine

THE excretion of a number of water-soluble azo dyes in rat bile, following intravenous injection, has been previously examined by us[1] as a means of estimating the likely extent of uptake and metabolism of these compounds Among the dyes examined, two phenylazopyrazolones provided highly contrasting results Tartrazine (1*a*, R^1 = COONa, R^2 = H) was virtually not excreted at all, whereas lissamine fast yellow 2*G* (1*b*, R^1 = CH_3, R^2 = Cl) was excreted quantitatively (Table 1) We have now obtained evidence showing that the carboxyl group of tartrazine is responsible for the difference in excretion

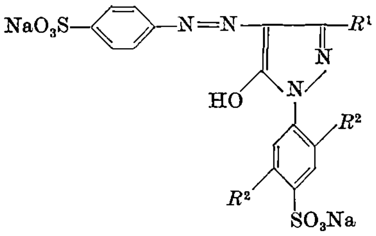

Fig 1

The ethyl ester of tartrazine (1*c*, R^1 = $COOC_2H_5$, R^2 = H) and 1-(*p*-sulphophenyl)-3-methyl-4-(*p*-sulphophenylazo-)-5-pyrazolone (1*d*, R^1 = CH_3, R^2 = H) were prepared by standard methods[2] and isolated as their disodium salts Dichlorotartrazine (1*e*, R^1 = COONa, R^2 = Cl) was similarly prepared, but could only be isolated by preparative chromatography of the reaction mixture using ethyl acetate / pyridine / water (3 1 1 by vol) as the developer The major band was eluted from the paper with hot methanol and recrystallized from the same solvent The compound possessed the expected ultra-violet spectrum and satisfactory analytical figures were obtained

The biliary excretion of these dyes was determined by our earlier method[1] The results are set out in Table 1

Table 1

Dye	Percentage excreted unchanged in bile (mean of four determinations)
Tartrazine	1
Dichlorotartrazine	25
Tartrazine ethyl ester	77
Lissamine fast yellow 2*G*	96
1-(*p*-sulphophenyl-)-3-methyl-4-(*p*-sulphophenylazo-)-5-pyrazalone	80

It is clear that in this series of compounds low excretion in the bile is correlated with the presence of a free carboxyl group in the 3-position of the pyrazolone ring Tartrazine (1*a*) and dichlorotartrazine (1*e*) are poorly excreted, while the remaining compounds all show high excretions Of these the high excretion of tartrazine ester (1*c*) is particularly significant since it rules out any possibility that the steric constraints placed upon (1*b*) and (1*e*) by the chlorine atoms make any more than minor contributions to their biliary excretions

The reasons for these differences are not yet clear Azo dyes can be reductively cleaved *in vivo*[3] and we have found amines derived from injected azo dyes in rat bile in several cases[4] However, following injection of doses of tartrazine sufficient to bring about some excretion of the dye in bile (about 2 mg) only the unchanged dye could be detected by paper chromatography No amines corresponding to reductive fission could be detected even after acid hydrolysis

Preliminary work on the urinary excretion of tartrazine has provided some additional information After intraperitoneal injection, dye is rapidly excreted in the urine This dye is a conjugate since it travels more slowly than tartrazine when chromatographed on paper The nature and amount of the conjugate are at present being investigated, but it appears likely that the carboxyl group is involved Again no amines corresponding to reductive cleavage could be found in the urine

The high resistance of these dyes to reductive fission *in vivo* is of great practical and theoretical interest It is possible that these dyes are not true azo compounds but substituted phenylhydrazones and we are at present attempting to define their fine structure by physical methods

PATHOLOGY

Serological Comparisons among Tissue Culture Cell Lines

IT has long been a question whether cells derived from normal tissues acquire some malignant attributes after long-term tissue culture, especially those cells which have become established *in vitro* as lines This has been a particularly vexing problem to pharmaceutical houses, necessitating the use of primary cell cultures for vaccine production Some cells of supposed normal derivation have been shown to produce tumours after inoculation into suitable recipients[1-4] and to assume the heteroploid pattern of malignant cells[5] It is the purpose of this preliminary report to present evidence that cells of known malignant origin contain antigenic material which is not found in cells of normal origin Suggestive evidence that this antigenic material is shared by cells of malignant human and murine tissues, thus transcending species barriers, will also be given

‡ Figures in parentheses indicate reciprocal of dilution of antigen showing complete fixation

The growth and extraction of HeLa and *J*111 cells have been described recently by us[6] The final aqueous supernates of the HeLa and *J*111 cells after fluorocarbon homogenization were adjusted to contain 2 mg of protein per ml and emulsified with equal volumes of complete Freund's adjuvant Rabbits received a total of 6 mg of either antigen in adjuvant as a series of six weekly intramuscular injections The rabbits were bled by cardiac puncture 10 days after the final injection and the sera stored at −20° C until used

All cells used for the extraction of test antigens were purchased as frozen pellets of spinner cultures from Microbiological Associates, Inc, Bethesda, Maryland, and were treated with fluorocarbon and assayed for protein, as described[6] Where no protein was detectable in a final supernate, this supernate was treated as if it contained 0 5 mg of protein per ml Either on this basis (for cells of normal origin) or from actual protein determinations, the antigens were adjusted to contain 100γ protein/ml The hæmolytic system used was as described[6], except that falling dilutions of each antigen were tested against an optimal concentration of both anti-HeLa and anti-*J*111 rabbit sera

The results of duplicate complement fixation tests using the 19 cell lines tested thus far against anti-HeLa and anti-*J*111 rabbit sera are given in Table 1 The results are expressed as the γ protein/ml required to cause complete fixation of 4 H_{100} units of complement in the presence of four units of antiserum A value of > 100 indicates that no fixation occurred, and the effective complement finding capacity of each antigen can thus be estimated in terms of γ of protein All the antigens extracted from cell lines of reported human malignant origin reacted with both antisera to varying degrees Of the eight cells of normal human origin, only the Girardi human heart showed any fixation of complement and that only at 100 γ/ml The same applies to the Salk cynomolgus monkey heart line It is not possible at the present time to state that these two reactions are *de facto* characteristic of malignancy as little is known of the antigenic purity of the extracts used to produce the antisera

An unexpected finding reported here was the observation that both the antigens extracted from murine lines *P*1534 and *Ca*755 fixed complement in the presence of antisera to both HeLa and *J*111 antigens Of further interest was the finding that no fixation was found using antigen of *G*99 This cell was reported[7] as a non-tumour producing clone of *Ca*755 Investigations are at present being extended to a variety of other cell lines of different animal origin in addition to studies to determine the true species of origin of the cells

Mono- and Di-amine Oxidase Activities of Human Tumours and Host Tissues

THE available information on the decarboxylation pathways of histidine and aromatic amino-acids in human cancer is incomplete

Histidine decarboxylase activity was found to be present in the basophils from chronic myelogenous leukæmic patients[1], and their blood histamine is greatly increased[2,3] No change of the histamine content was observed in fibroid growth as compared with normal human skin[4] Carcinoma of the lung were found to contain less histamine than the surrounding tissues of the patients[5] Histamine is abundant in human prostate adenomas[6]

Carcinoid tumours have large amounts of 5-hydroxytryptamine[7,8] Mono-amine oxidase activity was found to be low in human carcinoma[9], and in

Table 1 MONO- AND DI-AMINE OXIDASE ACTIVITIES OF HUMAN TUMOURS

Adrenals (metastatic anaplastic carcinoma of lymph node primary in breast	26 03	−1 32

lung and liver metastases[10] In carcinoid metastases and phæochromocytoma the low mono-amine oxidase activity was associated with increased amino-acid decarboxylation[11,12] Mono-amine oxidase activity was found normal in glia tumours[13] and argentaffin carcinoma[14]

The activity of mono- and di-amine oxidase of different human tumours and host tissues was determined as described elsewhere[15,16]

Table 1 shows that the mono-amine oxidase activity varies with the kind of tumour A tendency towards low activity is observed as in fast-growing tissues From Table 2 it can be seen that mono-amine oxidase activity is strongly decreased in the regenerating rat liver as compared with normal liver

Diamine oxidase was absent in all the tumours studied excepting the lymph node metastases of gastric adenocarcinoma As can be seen from Table 3, host tissues appear to have unchanged mono-amine oxidase activity and no histaminase activity was observed in them

RADIOBIOLOGY

Changes in Density of Blood Serum with Irradiation Dose and Post-irradiation Period

WE have shown that after the whole-body irradiation of rats using a 600 r dose the increase of density of their blood serum was statistically significant[1] This increase was not observed after some stress impulses as, for example, scorching and thirsting

This communication shows that these changes are dependent on time and on the whole-body irradiation dose

The method used was the same as before[1] The density was determined by weighing the serum which was measured by means of a microburette screw placed in the thermostat The measured volume was calibrated by redistilled water The required quantity of serum for one determination amounted to 0 25 ml Each sample was determined twice, and the average of the two values was taken Rats of the Wistar strain, weighing 150–200 g, were used Irradiation was carried out with the Makrophos' X-ray apparatus at 150 kV, 15 m amp, 0 5 copper filter, 100 cm focus distance, dosing 6 7 r /min

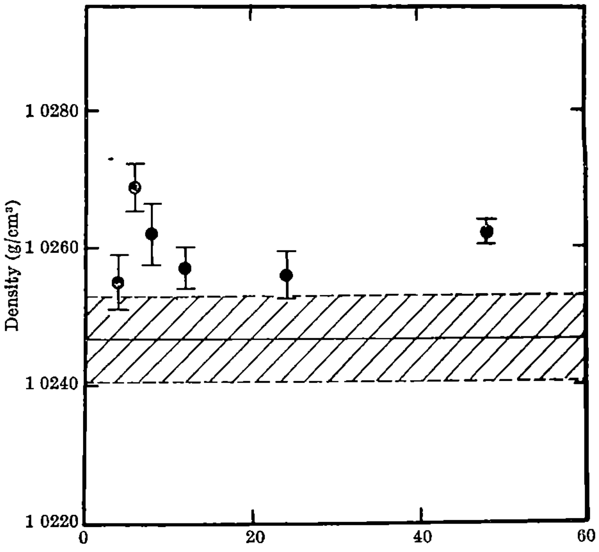

Fig 1

As illustrated in Fig 1, the maximum changes after an irradiation dose of 600 r were observed 6 h after the irradiation The abscissa indicates the density values in g/cm³, the ordinate represents the time period in hours The number of animals in the control group was 18, in the group observed 6 h after irradiation 12, the other group consisted of 6 rats The average values and the standard errors are also indicated The dashed line indicates the average and the standard errors in the controls

Fig 2 illustrates the dependence of the changes in the blood serum density 6 h after irradiation on the whole-body irradiation dose The abscissa gives the density values in g/cm³, the ordinate shows the

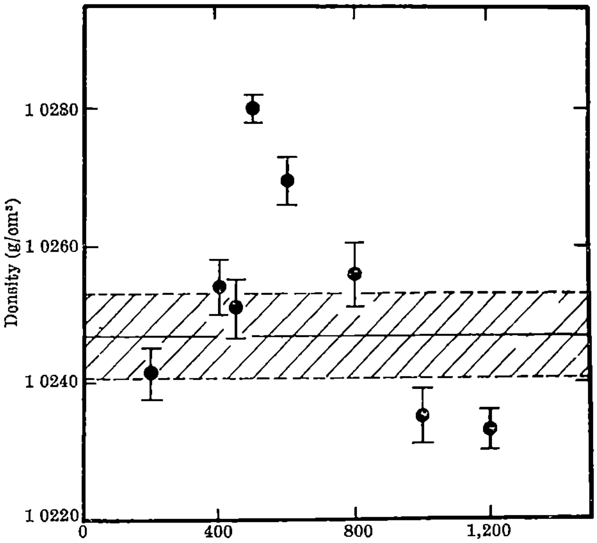

Fig 2

dose in r Here again the average values and the standard errors are given The dashed line indicates the average values and the standard errors in the control animals

A significant increase in the density of the blood serum was observed 6 h after the application of 0 2 mg *tris*-(β-chlorethyl amine hydrochloride) and 24 h after intravenous application of colloidal chromium phosphate labelled with phosphorus-32 in a quantity corresponding to an absorbed dose of 7,000 rads in the liver

From the results achieved, it follows that the changes in the density of the blood serum depend on the extent of the whole-body irradiation dose and on the period of irradiation Maximum changes were observed 6 h after the application of a 500 r irradiation dose Knowing that the changes in the blood serum density are subjected to a series of factors, we presume, however, that the disturbance in proteosynthesis and the disturbance in DNA creation leads to the accumulation of catabolites in the blood These catabolites, in the same way as the decay products, especially those of the white blood elements can take part in the changes affecting the serum density It is also possible that a change in the space configuration of the protein macromolecules and the altered conditions in the water quantity bound on proteins may play here an important part In doses greater than LD_{100} it is necessary to take into consideration the disturbed renal function These factors are being examined at present, and we are investigating the correlation between the changes in blood serum density and other changes in the physico-chemical properties of blood

Complex Amine Oxides with Radioprotectant Properties

Previous reports[1–3] have shown that certain amine oxides can increase total survival after lethal whole-body X-irradiation Recently it was found that the complex compounds in Table 1 were active radioprotectants

Groups of 20 *CF*-1 male mice were given orally 250 mg/kg of the compounds 24 h prior to exposure to 600 r X-irradiation under our usual conditions[3] The degree of radioprotection based on total survival varied from 15 to 40 per cent, although the —N=C— structure required for activity was present in all compounds These differences in activity may be related to substituent groups exerting directing influences on the molecules and forcing the radiation-induced oxidizing radicals to attack substituent groups which are less readily oxidizable Both isoimidazole derivatives present two methyl groups where such oxidations could occur, but directing influences could cause the oxidation to occur in the 4 position of the benzene ring Under such conditions one would expect the compound containing the phenyl group to be more potent because hydroxylation is a one-step process whereas the tolyl group usually is converted to the corresponding acid by a three-step process The results in Table 1 support this explanation

Table 1 Effect of Complex Amine Oxides on Survival after X-Irradiation

Medication	ST_{50} and range	Slope and range	Mortality Final (%)	Day
Saline control	13 1 (10 8–5 9)	1 54 (1 34–1 78)	90	30
4,5-dimethyl-2-(*p*-tolyl)-1,3-isoimidazole-1,3-dioxide	15 5*(12 8–18 8)	1 52 (1 30–1 78)	75	30
4,5-dimethyl-2-phenyl-2-isoimidazole-1,3-dioxide	—	—	65	30
3,4-diphenyl furazan-1-oxide	—	—	60	30
Saline control	8 0 (6 6–9 7)	1 55 (1 35–1 78)	95	17
5-Quinazolinol,3-oxide	—	—	55	30

ST_{50}, day on which 50 per cent of animals are expected to be still alive Confidence limits are calculated at $P=0\ 05$ (ref 4) All drugs 250 mg/kg orally 24 h pre-irradiation

*Not significant at $P=0\ 05$

Similarly, radiation-induced hydroxylation of the phenyl group could explain its radioprotectant activity The quinazolinol compound can exist *in vivo* in the keto or lactam form and should behave analogously to a hydroxyquinoline This would form the —N=C— structure, and the substituent group in position 4 could direct the oxidation to the 2 position Previous work[1,2], as well as these results, would support the foregoing radical trapping mechanism as an explanation for the radioprotectant activity of the compounds in Table 1 Furthermore, such results indicate a direction for further research in the development of new and better radioprotectant drugs

We thank Parke-Davis and Co for the quinazolinol compound and Lilly Research Laboratories for the other compounds used in this investigation, which was supported by Contract *AT*(04-1)*GEN*-12 between the Atomic Energy Commission and the University of California

Indirect Action of X-Radiation on Mammalian Cells

Ionizing radiations may impair the reproductive capacity of cells either by directly altering specific biochemical sites or indirectly by giving rise to free radicals in water which then react chemically with specific sites In the frozen state the mobility of free radicals is hindered, and consequently the radiosensitivity of cells reduced to an extent that depends on the degree to which the indirect mechanism is involved

Although the demonstration that radiosensitivity of a system is reduced in the frozen state does not by itself constitute proof that the indirect mechanism is involved, since a number of physico-chemical factors (oxygen sensitization[1], temperature dependence of radiosensitivity independently of change in state[2,3])

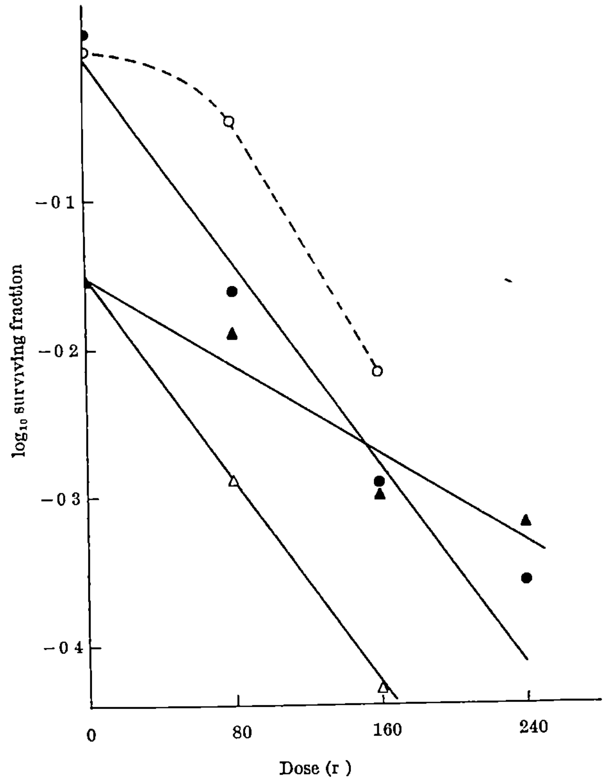

Fig 1 Dose-survival curves for *S*3 HeLa cells irradiated at room temperature without added dimethyl sulphoxide (*A*, O), with 10 per cent dimethyl sulphoxide at room temperature (*B*, ●), at −79° (*C*, ▲), and at room temperature after thawing (*D*, Δ) Each point plotted represents the mean for up to five replicate determinations Data at zero dose were included in calculating all regression lines except curve *A*

may also contribute to the phenomenon, nevertheless, for single cells, and especially for mammalian cells which, unlike spores or seeds, cannot exist in the desiccated state, this may constitute the strongest type of evidence at present available[4]

Bacteria[5] and seeds[6] have been shown to be more radioresistant when frozen, but surprisingly the opposite effect has been reported for mammalian cells In a series of carefully controlled experiments, Lasnitzki[7] showed that mouse ascites cells when irradiated *in vivo* were considerably more sensitive at − 79° C than at room temperature, both to γ- and to X-rays

We have explored this phenomenon in another mammalian cell line—HeLa *S*3 strain derived from a human cervical carcinoma—by using the single-cell plating technique described by Puck[8] The cells were cultured under an atmosphere of 5 per cent carbon dioxide in a medium consisting of 20 per cent pooled human AB serum, 10 per cent horse serum and 70 per cent Eagle's medium (Difco, Detroit) Reproductive capacity was demonstrated by the ability of single cells to form colonies Immediately before freezing, dimethyl sulphoxide was added to give a final concentration of 10 per cent[9,10] Freezing was carried out at the rate of 1° C per min down to −15° C and then as rapidly as possible down to −79° C [11] One hour after freezing cells were irradiated with 140 kVp X-rays at a dose-rate of 240 r /min, with doses of 80, 160 and 240 r respectively, and were allowed to remain at −79° C for a further 24 h, when they were rapidly thawed by immersing in a water-bath at 38° C Three control series were investigated at the same time In the first two, cells were subjected to the same irradiation procedure but without subsequent freezing and thawing, with and without the addition of dimethyl sulphoxide respectively In the third series irradiation was carried out immediately after thawing

67 per cent of the cells survived freezing alone Dimethyl sulphoxide at a concentration of 10 per cent did not reduce their viability, but appeared to eliminate the 'shoulder' of the dose-survival curve usually exhibited by this strain of cell (Fig 1 compare curve *A* with curves *B*, *C* and *D*) In the frozen state there was considerable reduction in radiosensitivity, the inactivation dose, D_{37}, being 573 ± 113 r (*S E*), compared with 252 ± 36 r for cells irradiated at room temperature (curves *C* and *B*, respectively) The possibility arose that cells which had survived freezing were also more resistant to irradiation or that freezing may have altered cells in a manner to confer radioresistance However, D_{37} for cells irradiated immediately after thawing was 252 ± 72 r (curve *D*) This difference in the value of D_{37} for cells irradiated in the frozen state from that for cells irradiated at room temperature or on thawing was significant by Student's *t* test ($P \leqslant 0\ 01$ and $0\ 02 < P < 0\ 05$, respectively)

Our results therefore provide evidence for the indirect action of X-radiation on mammalian cells The difference between our results and the paradoxical finding of Lasnitzki may reside in the difference in experimental conditions Principal among these was that we used an entire *in vitro* system, whereas Lasnitzki adopted an *in vivo* test of viability, in which tumour–host immunological relationships may have played a prominent part Moreover, we examined radiosensitivity over a comparatively low dose-range in which the effects on reproductive capacity conform to the predictions of classical target theory A single, comparatively high, dose of 1,500 r was used in the *in vivo* studies and it may be difficult to interpret such results without more knowledge of the shape of the dose-survival curve for the cell system concerned

We thank Dr J H L Playfair for his help in freezing the cells, and Miss P M Scully for technical assistance

BIOLOGY

Connexion between Protein Synthesis and Salt Absorption in Plant Cells

From an examination of the effects of various factors, for example, temperature, external *p*H, and provision of a suitable nitrogen source on salt absorption and protein synthesis in tissue slices, Steward and Millar[1] concluded that the two processes are closely related The possibility that the relationship is an indirect one through a common dependence on respiratory energy was not at that time excluded New evidence for a more direct connexion came from the observation that chloramphenicol, which is known to be a specific inhibitor of protein synthesis in micro-organisms[2] and in higher plants[3], also inhibits salt absorption in storage tissue slices[4]

More recent experiments have shown that chloramphenicol interferes both with the uptake of amino-acids labelled with carbon-14 by slices of carrot root and with the incorporation of the label into newly synthesized soluble proteins of the tissue It thus appears to be confirmed that chloramphenicol inhibits protein synthesis in the tissue under conditions in which salt absorption is also prevented The details of these experiments and a discussion of the results are presented elsewhere[5]

MacDonald *et al* [6] have demonstrated that net protein synthesis occurs in tissue slices cut from the storage organs of various plants and transferred to aerated tap water They have suggested that the rate of synthesis depends on the concentration of nitrate ions in the solution In the present investigation, the effects of washing carrot tissue in various solutions on the amount of protein synthesized and potassium taken up were examined in an attempt to discover whether any quantitative relationship between the two processes could be demonstrated The results presented in Table 1 show that whereas the amount of protein synthesized in the presence of potassium chloride did not differ significantly from that synthesized by tissues suspended in distilled water, potassium nitrate increased the rate of synthesis by about 3 times The potassium content of slices incubated in potassium nitrate solution on the other hand was only about 1 2 times as great as that of slices aerated in potassium chloride solutions It is evident that nitrate has a much greater effect on protein synthesis than it has on potassium accumulation When chloramphenicol was supplied in the presence of potassium nitrate, both the synthesis of protein and potassium uptake were inhibited by about 50 per cent

The present results may be most simply explained as follows (Fig 1) Various kinds of protein (P_1, P_2, P_3, P_4, etc) are synthesized from common precursors (X) which may be the amino-acids, in a series of reactions, and one of the steps in each case is inhibited by chloramphenicol The accumulation of potassium ions is perhaps related to the synthesis of a particular kind of protein (P_1) which may be located in the surface membrane of the cell and act as an ion carrier through a cycle of breakdown and resynthesis The remainder of the proteins in the cell may be synthesized without participating in ion absorption and it is possible that they are broken down and resynthesized less rapidly than are the surface membrane proteins Because the latter represent only a small fraction of the total proteins in the cell, it may be difficult to determine their rates of turnover and to correlate these with rates of salt accumulation Nevertheless an attempt to accomplish this is being made

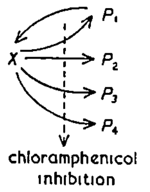

Fig 1. Cycle of synthesis and breakdown during which P_1 acts as an ion-carrier

Freeze-Drying of Plant Tissues

Freeze-drying has proved a valuable technique in cytological investigations of animal cells and tissues, but it has not met with the same success when applied to plants[1] Frozen-dried animal tissues are usually embedded in de-gassed paraffin wax which is later removed from the sections with xylol Unfortunately, infiltration of frozen-dried plant tissue with molten paraffin or ester wax has proved extremely difficult, if not impossible Previous failures may have been due to the large vacuoles and intercellular spaces which make plant cells particularly liable to damage during infiltration These capillary spaces fill with air when frozen-dried tissues are brought from the vacuum chamber into the atmosphere and, even when subsequent infiltration is done *in vacuo*, the trapped air probably prevents complete impregna-

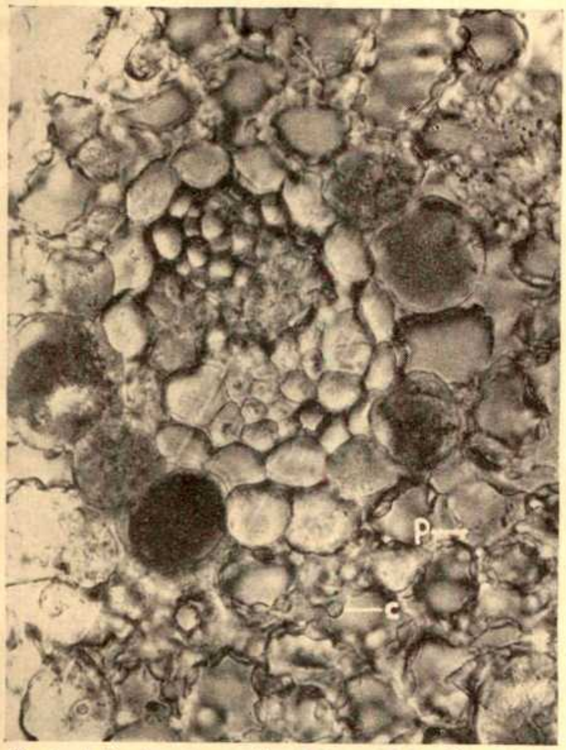

Fig. 1. A 15-μ transverse section of frozen-dried seedling oat leaf embedded in 'Epon 812', showing a vascular bundle surrounded by mesophyll cells in which chloroplasts (*c*) and cytoplasmic particles (*p*) are preserved. (× *c*. 950)

tion. Another likely cause of damage is the removal of lipoidal substances from the membranes in plant protoplasm by molten paraffin wax and fat solvents.

A new freeze-drying apparatus has been developed which incorporates improvements in operation and tissue treatment. The vacuum chamber design is based on a theoretical analysis of the physical requirements for efficient low-temperature drying. A description of the apparatus is to be published elsewhere. The purpose of this communication is to report the preservation of cell contents in frozen-dried plant tissues. Under the light microscope, cellular and protoplasmic morphology compares favourably with the structures seen in living cells.

Two methods of post-drying treatment were used: (*a*) direct embedding with epoxy resin 'Epon 812'; (*b*) post-drying fixation with osmium tetroxide in benzene followed by embedding in ester wax. 'Epon 812' is an embedding medium used in electron microscopy, and a detailed procedure for embedding chemically fixed specimens has been published by Luft[2]. The new freeze-drier incorporates an embedding side-arm which forms part of the glass vacuum chamber and allows the isolation of the embedding medium during the drying period. Such an arrangement is essential when embedding with synthetic resins because the fluid monomer would otherwise sublime on to the 'cold finger'. The complete monomer, including the catalyst, is placed in the bulb of the embedding side-arm and degassed prior to the start of drying. When the specimens are dry the glass isolation tap is opened and the monomer is poured over the specimens. After 1 hr., air is admitted and the specimens are transferred to resin-filled capsules. As Luft explains, final hardness can be adjusted by varying the proportion of resin constituents. To obtain sections for observation under the light microscope, a block similar in hardness to butyl methacrylate can be cut with a steel knife. Direct embedding with 'Epon 812' avoids the use of solvents and no air is allowed to enter the dry tissue. Thus liquid/gas interfaces do not pass through the tissue, and diffusible cell compounds are less likely to be displaced. Fig. 1 is a photomicrograph from a 15-μ transverse section of a small (1 × 1 × 0·5 mm.) seedling oat leaf specimen embedded in 'Epon 812' after 4 hr. vacuum drying at − 30° C. The section was observed and photographed without removing the 'Epon' matrix. There is very little distortion in the tissue and the preservation of chloroplasts and cytoplasmic particles is clearly illustrated.

If the specimens are not required for cytochemistry or microscopic autoradiography, an effective method of post-drying fixation is to introduce 0·1 gm. of osmium tetroxide in 5 ml. of benzene, again using the embedding side-arm to deliver the fluid on to the specimens. Post-drying fixation is judged visually and leaf pieces usually require 1–2 hr. Sometimes specimens do not sink in benzene and they have to be passed through ethyl alcohol to xylol, with the usual intermediate baths. Once the specimens have sunk they can be transferred directly to capsules of molten ester wax. Fig. 2 is a 5-μ transverse section of frozen-dried soybean leaf fixed with osmium tetroxide in benzene and embedded in ester wax. The section was flattened on an aqueous solution of Mayer's albumin, and the ester wax was removed with xylol. Fig. 2 shows that the structural arrangement of the tissue was preserved in freeze-drying. Within cells the parietal position of chloroplasts and well-defined vacuoles indicate that the tonoplast and cell contents were not disturbed. A microscopic system of thread-

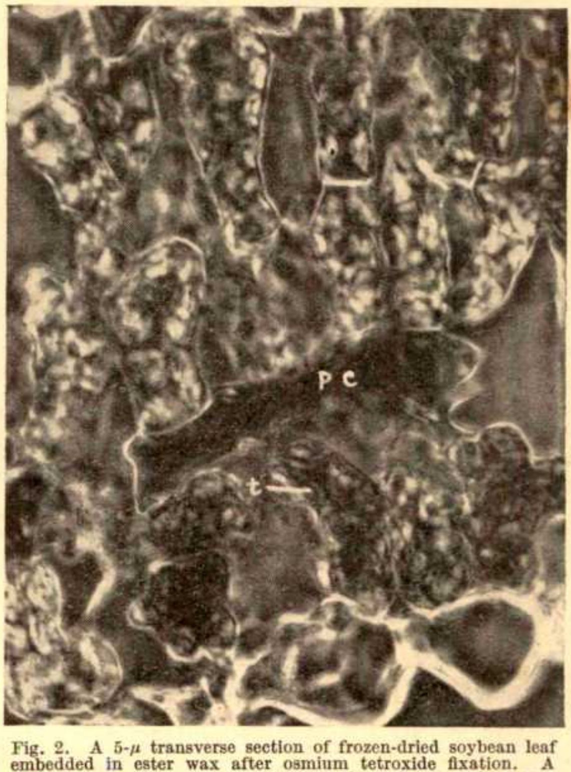

Fig. 2. A 5-μ transverse section of frozen-dried soybean leaf embedded in ester wax after osmium tetroxide fixation. like structures is revealed within mesophyll cells between chloroplasts and overlying chloroplast membranes. The paradermally oriented parenchyma cell which occurs between the palisade and spongy mesophyll cells is a structural feature not previously revealed in leaves.

Fatty Acid Control of Ethane Production by Sub-cellular Particles from Apples and its Possible Relationship to Ethylene Biosynthesis

Burg and Burg[1] have pointed out that the gas evolved in incubation mixtures of thiomalic acid and sub-cellular particles from apples and tomatoes was in fact not ethylene, as previously reported[2]. However, the appearance of an 'ethylene-like' gas which chromatographed very close to ethylene was confirmed. The purpose of this communication is to identify the 'ethylene-like' gas, to report that linolenic acid may be an important component of the enzymatic system, and to indicate the possible pertinence of this system to the pathway for ethylene biosynthesis in plant cells.

The 'ethylene' evolved in the enzymatic system of Lieberman and Craft[2] and the 'ethylene-like' gas of Burg and Burg[1] is, in fact, ethane. This was established by co-chromatography of authentic samples of ethane and the 'ethylene-like' gas evolved in the enzymatic systems. A typical gas chromatogram of authentic ethylene, authentic ethane, the 'ethylene-like' gas, and a co-chromatogram of ethane and the 'ethylene-like' gas is shown in Fig. 1. The co-chromatograph yields one peak which chromatographs exactly like authentic ethane. D. F. Meigh, of the Ditton Laboratory (personal communication), utilizing some of our freeze-dried particulate preparations earlier identified ethane as the 'ethylene' gas of Lieberman and Craft[2]. Therefore the enzymatic particulate system from apples and tomatoes, when incubated with thiomalic or thioglycolic acid and co-factors, produced ethane.

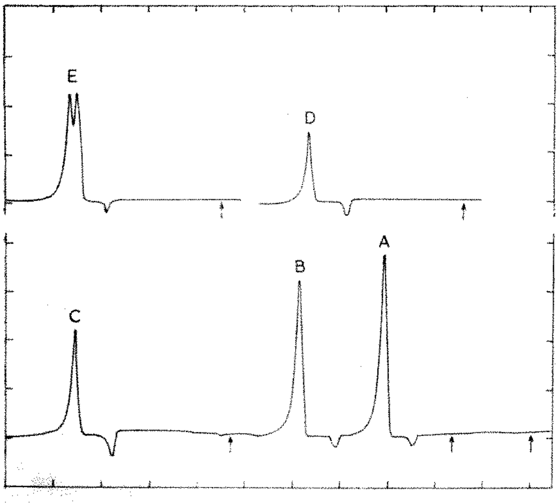

Fig. 1. Gas chromatogram of (*A*) authentic sample of ethylene, (*B*) authentic sample of ethane, (*C*) volatiles evolved by apple particles, thiomalic acid and co-factors, (*D*) co-chromatograph of *B* and *C*, (*E*) co-chromatograph of authentic ethylene and ethane. Samples were inserted at times indicated by arrows. The graph reads from right to left. Each horizontal division corresponds to 1 min. The gas chromatographic system was similar to that previously described (ref. 4)

Table 1. DEPENDENCE OF ETHANE-PRODUCING SYSTEM ON A LIPID CONSTITUENT AND ITS SUBSTITUTION BY UNSATURATED C-18 FATTY ACIDS

Flask contents*	µl. ethane (× 10⁻³) per mgm. protein/hr.
Particles† + co-factors + thiomalic acid (no lipid)*	1·6
,, + ,, + ,, ,, + natural lipid	5·6
,, + ,, + ,, ,, + palmitic acid	1·2
,, + ,, + ,, ,, + stearic acid	1·2
,, + ,, + ,, ,, + methyl stearate	1·4
,, + ,, + ,, ,, + methyl oleate	2·4
,, + ,, + ,, ,, + methyl linoleate	6·0
,, + ,, + ,, ,, + methyl linolenate	20·0

* Each flask contained: 50 µmoles thiomalic acid, 3 µmoles adenosine triphosphate, 40 µmoles PO_4, 200 µmoles acetate buffer *p*H 4·5, and 1·0 ml. enzyme containing about 20 mgm. protein. 25 µmoles fatty acid or ester was added to flasks containing these. The natural lipid was obtained and concentrated by extracting 1 gm. of freeze-dried powder with 100 ml. ethyl ether (0° C.) and evaporating to dryness. The residue was taken up in water containing a drop of 'Triton *X*-100'. A three-times concentrated lipid preparation was added to flask containing natural lipid.

The methyl esters of the fatty acids were pure compounds (99 per cent) obtained from the Hormel Institute.

† Particles were prepared by homogenizing apple pulp in 0·4 *M* sucrose. The homogenate was centrifuged for 5 min. at 1,000*g* followed by 1 hr. at 15,000*g*. The final pellet was suspended in 0·1 *M* acetate buffer *p*H 4·5 and freeze-dried. One gram of powder contained about 300 mgm. of protein.

The ethane-producing particulate system requires the presence of an unsaturated fatty acid. This was demonstrated by the fact that the system was almost inactivated following ether extraction of the freeze-dried particulates but activity was restored by addition of the lipid fraction or by addition of oleic, linoleic, or linolenic acids or their methyl esters. As the results in Table 1 show, saturated fatty acids gave negative results. A slight stimulation was obtained with oleate, but a much greater effect was observed with linoleate and linolenate. Linolenate was about three times as effective as either the natural lipid or methyl linoleate. It is not yet clear whether linolenate is functioning as a co-substrate or as a co-factor in the reaction. One hypothesis visualizes thiomalic acid and linolenate forming an adduct, which breaks down and releases a 2-carbon fragment which may be transformed to either ethane or ethylene. The available evidence, however, appears to favour the thesis that ethane is produced entirely from thiomalic acid.

These findings seem to have some bearing on the problem of ethylene biosynthesis in plants. While ethane and ethylene may be synthesized through very different pathways in the cell, some evidence points to a relationship between them. Usually a small quantity of ethylene is associated with ethane production by the isolated enzymatic system. However, ethylene is sometimes difficult to observe because of the relatively large quantity of ethane produced. When ethane production is limited, either by sampling after only 1 or 2 min. of incubation or after inhibition, the amount of ethylene produced is comparatively large relative to ethane.

Apples normally produce much less ethane than ethylene. Meigh[3] reports a ratio of ethylene to ethane of 14,000 to 1 in whole apples. However, when apples are homogenized and incubated in buffer the amount of ethane found is approximately equal to ethylene. While all these factors tend to suggest a biochemical relationship between ethane and ethylene, it is at present premature to state what this relationship is However, present information suggests either that one may be a precursor of the other or that they may be derived from a common source

Use of an Integrating Stage for Measurement of Wood

IN OUR search for a less time-consuming method for measuring anatomical components and spaces within samples of wood of varying ages and heights in trees, we have found that the use of an integrating stage attached to the stage of a microscope has proved satisfactory and reliable[1] Accumulating knobs are provided to measure units in hundredths of millimetres for six different readings in one traverse, and obtaining percentage values for each component is a simple operation.

We have been able, by the use of cores approximately 5 5 mm in diameter and taken vertically from cross-sections of tree trunks at different heights, to obtain wood specimens of known age from the pith and at different heights in trees After specific gravity determinations these specimens are boiled in water to expel the air and are stored in 70 per cent ethyl alcohol Free-hand sectioning for a complete and precise transverse section of 20–30μ has been possible in eastern cottonwood and black walnut used thus far in our work The sections are then carefully mounted in chloro-iodide of zinc solution[2] on microscope slides and are covered with No 0 or No 1 coverglasses This stain when properly prepared gives a bluish coloration to the inner wall of gelatinous fibres and aids in their identification

In our first analysis of wood samples from eastern cottonwood camera lucida drawings were made of cell wall and lumen components along known traverses and the measurements were taken from these In the use of the integrating stage method accumulation of as many as six readings were taken simultaneously and percentage values were computed from the totals Furthermore, it was possible to return to the beginning of the same traverse and repeat for checking purposes, or for re-assigned knobs for additional measurement values We have used magnifications of 500× satisfactorily for sections 30-μ thick

An analysis of variance for wood samples from the same tree of eastern cottonwood showed the two methods did not give significantly different results The measurements expressed in percentages with the integrating stage method are, therefore, shown to be reliable. This, together with the fact that the operator's time is reduced by more than one-half, makes the method one to be highly recommended

Thyroid Feeding of Salmon Parr

IN the spring of 1961, the Salmon Research Trust of Ireland, at its Research Station at Newport, Co Mayo, conducted an experiment on feeding fresh thyroid to one-year-old salmon parr, on a small commercial scale

The experiment began on February 20 and terminated on May 1—a duration of 69 days This period was chosen as being that in which salmonid fish could be expected to show maximum response to thyroid stimulation[1] The fish were large-grade parr, from the same source, contained in two 15-ft diameter circular rearing ponds, each having approximately the same population density (controls, 3,568 , experimentals, 3,838) Both groups of fish were fed three times daily with raw minced beef liver ; but the experimental fish received 20 per cent of their diet as raw, minced beef thyroid This dosage-rate was selected as the optimum in the light of earlier experiences with rainbow trout[2]

The fish fed and survived well during the period of the experiment, when mortalities were virtually the same, averaging less than one a day in each pond

During May 3–6, all 1+ smolts were graded out of each pond, when it was found that the thyroid-fed group yielded 913 smolts, against 510 in the controls This constitutes an 80 per cent increase in the production of 1+ smolts in comparable populations, which is felt to be economically significant

The percentage smolt transformation in each pond was as follows

Controls,	510 smolts	2,993 parr	14 7 per cent
Experimentals,	913 smolts	2,853 parr	24 2 per cent

During the first month of the experiment, the control fish increased in mean length from 72 to 78 mm, while the experimentals increased from 71 to 88 mm Unfortunately, the mean lengths of the two groups were not measured at the end of the experiment, but the 510 control smolts averaged 130 mm while the 913 experimental smolts averaged 134 mm Clearly, the experimental group was composed of larger fish where 24 2 per cent of the population were 4 mm longer than 14 7 per cent of a comparable group This effect of thyroid treatment on the growth of salmonid fish has been noted for rainbow trout[1]

During the grading-out of the smolts, it was noticeable that those of the thyroid-fed group were markedly more silver than those of the control group, and that there were no fish in the intermediate 'parr-smolt' ('silvery-parr') stage

A large proportion (721) of the thyroid-fed smolts were tagged or fin-clipped and liberated in fresh water, some two miles above a counting fence and trap, situated at the head of tidal water Their survival and speed of migration, as measured at the trap, were exactly comparable with results from normal, hatchery-reared 1+ smolts. There are some grounds for believing that thyroid treatment could improve survival of smolts during the period of osmotic stress when they first enter tidal water[3,4]. This may apply more particularly to hatchery-reared smolts which necessarily have been subjected to some handling.

In this small experiment there was an increase of 80 per cent in the production of 1+ smolts for an increase of not more than 25 per cent in the feeding costs for the first year. However, had these 400 fish not become 1+ smolts, the cost of keeping them for a further full year would have been considerably more than the cost of thyroid material used in transforming them into 1+ smolts. The comparison in other districts may be even more favourable than in County Mayo, where the cost of thyroid material is high, relative to that of low-grade liver. Experimental work on lowered dosage-rates is planned for the coming season.

Culture of *Spinellus*

MOULDS of the genus *Spinellus* of the Mucorales are generally regarded as being obligate parasites of agarics, particularly those belonging to the genus *Mycena*. Recently, Ellis and Hesseltine[1] reported that they had grown a species of *Spinellus* in pure culture; they noted the difficulty of making the spores germinate, and demonstrated the necessity for a relatively low temperature (below 20° C.) for growth.

Last autumn, a culture of *Spinellus* sp. was obtained from a parasitized fruit-body of *Mycena galopus*. The isolation was made by placing spores on a medium, later referred to as the 'basal medium', containing glucose, salts and yeast extract. A rapidly growing mycelium developed, producing numerous sporangia resembling those on the parasitized agaric. The mould has since been maintained in culture, using mycelium for inoculation as it proved to be very difficult to make the spores germinate. Various natural media have been tried, as well as the basal medium, and 5 per cent corn-meal agar also gave good growth, although others seemed less suitable.

This isolate, like that obtained by Ellis and Hesseltine, was extremely sensitive to temperature. No growth was obtained with cultures kept above 23° C and the optimum seemed to be about 20° C. At this and lower temperatures numerous sporangia were produced, with sporangiophores up to about 1.5 cm tall. Cultures incubated at 22°–23° C produced fewer sporangia, containing fewer spores, and with much shorter sporangiophores.

The spores from cultures grown at a low temperature (13° C. was used in these experiments) were elongated in form, with a ratio of length/breadth of about 3 : 1. Cultures grown at 22.5° C. produced relatively shorter and broader spores with a length/breadth ratio of about 2 : 1. The actual size of the spores varied somewhat according to the medium but the relative shapes were the same on different media and seemed to depend on the temperature at which the culture had been grown.

Various attempts have been made to determine the conditions necessary for spore germination and some relevant observations have been made. Spores germinate readily in contact with the fruit-body of a suitable agaric but only rarely on culture media. Some of the broader spores produced by cultures grown at 22.5° C. on corn-meal agar or basal medium germinated in water or nutrient solutions or on agar media, whereas spores produced by cultures grown at 13° C. did not germinate under these conditions.

Mycelium which developed from germinated spores produced, when grown at 13° C., the types of sporangia and spores characteristic for that temperature. There is thus no permanent change induced by growth at 22.5° C., but the spores produced differ in their shape and ability to germinate from those produced at lower temperatures. This presumably explains the successful initial isolation of *Spinellus*, as the spores used came from sporangia which had developed in the laboratory, at a temperature which was probably suitable for the production of the broader type of spore and the isolate could have resulted from the germination of one or more of these. Previous unsuccessful attempts had been made to isolate from sporangia developed in the field, and the spores, presumably of the narrower type, would not germinate on culture media.

Apart from bringing them into contact with a suitable agaric fruit-body, one other way has been found of obtaining some germination of spores at lower temperatures. This was to place them in association with various unidentified bacteria, which were first acquired as contaminants. The substance which stimulates germination appeared to diffuse through 'Cellophane' but has not so far been demonstrated in a Seitz filtrate of liquid cultures of the bacteria.

A more detailed account of these investigations will be published later and it is also hoped to study further the factors necessary for spore germination in *Spinellus* and other aspects of its relationship with its hosts.

ENTOMOLOGY

Identification of Iso-Amyl Acetate as an Active Component in the Sting Pheromone of the Honey Bee

THE sting of the honey bee (*Apis mellifera* L.) carries volatile substances which incite bees to aggression. This was first demonstrated by Huber[1], who elicited attacks by the guard bees when he placed freshly excised stings or the odour of stings near the hive entrance. Free[2] found that cotton balls containing stings were more frequently stung than control balls[3].

When not in action, the sting is retracted entirely within the sting chamber of the bee's abdomen. However, in the event of attack, the sting is quickly protruded and thrust into the enemy. The worker bee is usually unable to withdraw her barbed sting from the skin of vertebrates. Thus, the sting with its motor apparatus and glands is torn from the bee along anatomically predetermined breaking lines

During this investigation it was noticed that stings which were left behind by stinging bees had a sweet scent reminiscent of the odour of banana oil. Although protrusion of the sting by the bee produced the scent, maximum release was observed when the sting was detached. The characteristic odour was present in the stings of guard and foraging bees, but was absent in the stings of queens and of very young workers.

When presented at the hive entrance, stings from newly hatched bees did not agitate the guard bees. However, a cotton ball containing stings from older bees and exhibiting the characteristic banana oil odour aroused the guard bees, who attacked and stung it.

Because of the alarm and attack behaviour which it evidently releases in bees, the sting odour is to be included in the pheromones[3]. Chemical identification of one of the active principles in the sting pheromone of the honey bee is reported here.

Thirty stings were removed from bees, macerated immediately in 20 µl. of carbon disulphide, cooled in dry ice, and centrifuged, yielding approximately 12 µl. of solution. Gas chromatographic separation of 5 µl. of this solution was carried out using a Perkin–Elmer 154C vapour fractometer equipped with a flame ionization detector. The 4½ ft. × ¼ in. columns were packed with 10 per cent of liquid phase on 160–170 mesh 'Anakrom U' support. The carrier gas was nitrogen. Fig. 1 is a typical, although highly attenuated, gas chromatogram which was run at 130° C using a column containing 'Carbowax 1500' as the liquid phase. Peak No. 1 is due to the solvent, and No. 4, coming off at 1·75 min., was investigated further as it was a major component of the volatiles contained in stings of guard and foraging bees. By comparison of retention times of this fraction with known compounds on four different columns (Table 1) it was identified as iso-amyl acetate. Stings of queens and newly hatched workers did not contain iso-amyl acetate as the gas chromatograms showed only the solvent peak.

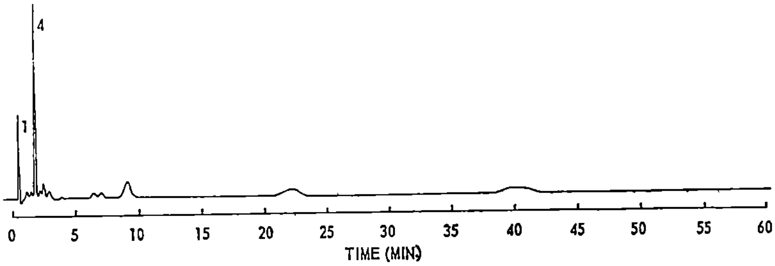

Fig. 1. Gas chromatogram of an extract of bee stings. Conditions: 10 per cent 'Carbowax 1500' on 'Anakrom U' at 130° C

Table 1. COMPARISON OF RETENTION TIMES OF A FRACTION FROM STINGS WITH ISO-AMYL ACETATE

Liquid phase	Column temperature (° C)	Retention time (min.) Fraction 4	Retention time (min.) *iso*-Amyl acetate
'Carbowax 1500'	130	1·75	1·75
	80	4·05	4·05
'Apiezon L + 1 per cent H_3PO_4'	130	1·70	1·70
	90	7·05	7·00
'Silicone 550'	130	2·50	2·45
	90	8·05	8·05
'Diethylene glycol succinate polyester'	110	1·82	1·80
	80	3·20	3·20

For the infra-red analysis an extract from 700 stings was chromatographed and fraction No. 4 was trapped and transferred in carbon tetrachloride solution to a 0·10-mm. ultra-micro-cavity cell. The infra-red spectrum (Fig. 2A) was obtained using a Perkin–Elmer model 21 spectrophotometer equipped with a lens-type beam condenser. This spectrum was identical with that of an authentic sample of iso-amyl acetate obtained under the same conditions (Fig. 2B).

The amount of iso-amyl acetate recovered from stings was estimated to be approximately 1 µgm. per sting. To our knowledge this is the first reported occurrence of iso-amyl acetate in animal tissue.

Authentic iso-amyl acetate was mixed with paraffin oil and the mixture absorbed in cotton balls. When presented at the hive entrance the balls treated in this way did alert and agitate the guard bees; however, cotton balls which contained an equivalent number of odoriferous stings, in addition to agitating the guard bees, incited them to sting. This suggests

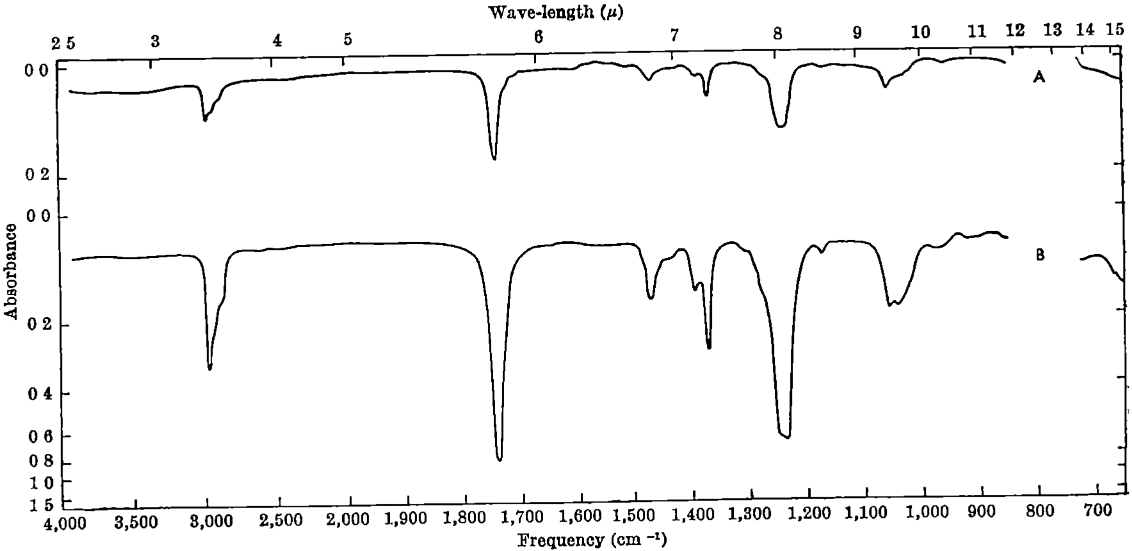

Fig. 2. The infra-red spectra of fraction 4 of bee stings (A) and of iso-amyl acetate (B) in carbon tetrachloride

that iso-amyl acetate is only one of the active components of the sting pheromone

Host Selection and Number of Eggs per Oviposition in the Egg-Parasite *Trichogramma embryophagum* Htg.

It has been shown by Salt[1,2] and Laing[3] that the behaviour of *Trichogramma* in parasitizing host eggs can be divided in the following elements

(*a*) The parasite makes random movements on the substrate and is visually attracted by small objects which rise above the surface

(*b*) The parasite climbs up the object and spends some time in walking over its surface in a characteristic way, making intensive movements with the antennæ (here called drumming) If the object has already just been parasitized by *Trichogramma*, it will be rejected if the odour of the first female is still present on the chorion

(*c*) After drumming, the parasite starts drilling on the surface of the object, not only on eggs, but also on small seeds and grains of sand Odour, colour and texture of the surface of the object seem not to play a predominant part in stimulating the drilling act The object can be rejected, however, if its measurements are such that the development of the parasite in the inside is an impossibility[1]

(*d*) If the object is a host egg the chorion is eventually perforated and the parasite's eggs are deposited The host is rejected after perforation, however, if it has been parasitized before[2] or the embryo has reached an advanced stage in development[4,5]

In this series of acts the function of drumming is puzzling, because the act of drilling can be released whatever the kind of the object It has been suggested that the function of this curious behaviour is to give the host egg an odour in order to mark it as being parasitized The drumming act is characterized by criss-cross movements over the chorion, the parasites often take some steps backwards when they touch the substrate, turning and walking on in another direction, following the curve of the chorion until another meeting with the substrate causes a new change of direction The antennæ are alternately and quickly moved up and down

We observed just as Quednau did[6] that *Trichogramma* deposits a variable mean number of eggs in hosts of different size during a single act of oviposition (Table 1) Therefore, we deduce from this fact and the typical behaviour during drumming that the function of the latter act might be looked for in the determination of the size of the host egg This idea was supported by the fact that the time spent in drumming proved to be correlated with the size of the egg (Table 1)

Table 1 Duration of the Drumming Act and the Number of Parasite Eggs deposited per Oviposition

Host	Diameter of host egg (mm)	Mean duration of drumming (sec)	No of eggs		No of observations
			Mean	Range	
Ephestia kühniella	0 3	37	1 1	1–2	70
Bupalus piniarius	0 9	62	6 7	4–10	92
Ellopia fasciaria	0 9	71	8 2	6–10	10
Hyloicus pinastri	2 2	172	25	—	2
Dendrolimus pini	2 1*	—	—	24–34†	—

* In Holland † According to Ryvkin (ref 7)

Table 2 No of Eggs deposited in Eggs of *Ephestia kuhniell* after Drumming on a Host of Larger Size

First host Species	Diameter of egg	No of eggs		No of observations
		Mean	Range	
'Egg' of type 1	1 1	3 4	3–4	7
Bupalus piniarius	0 9	2 7	2–3	9
Dendrolimus pini	2 1	8 5	7–10	4
No of Eggs deposited in Eggs of *Bupalus piniarius* after Drumming on Eggs of *Ephestia*				
Ephestia kühniella	0 3	1 5	1–2	4

To prove this we have carried out the following experiments

(1) Artificial eggs were made by clumping together some 4–8, or even more, eggs of *Ephestia* with a mixture of gelatin and agar-agar If this cluster of eggs was dipped in the same mixture two or three times, a small sphere was attained, in which the *Ephestia* eggs in some places were very close to the periphery, being covered only by a very thin layer of the desiccated liquid (type 1) Without this dipping the *Ephestia* eggs protruded and were on most places separated from each other by deep incisions (type 2)

If 'eggs' of type 1 were offered to the parasite female the whole surface of the sphere was covered in the drumming performance and 4 1 eggs on the average (3–5 in 8 experiments) were deposited, if the parasite happened to drill in an *Ephestia* egg

If 'eggs' of type 2 were offered, then the drumming performance was nearly always limited to one protruding *Ephestia* egg and only one parasite egg was deposited in that host After the first oviposition the parasite proceeded to the second *Ephestia* egg of the same cluster, parasitizing this one in the same way, and so on

In the latter series there were two exceptions to the rule, in which the parasite deposited 3 and 2 eggs in one *Ephestia* egg In these cases, however, the parasite covered the whole and half of the cluster in its drumming performance, respectively Thus, the parasite conceived the 'eggs' in these cases wholly or partly as eggs of type 1

(2) Artificial eggs of type 1, *Bupalus* eggs or *Dendrolimus* eggs were offered, on which the drumming act was performed On the moment that the drilling act was started an *Ephestia* egg attached to the top of a hair was placed between the legs of the parasite and it was forced to accept this apparent host for drilling and oviposition This sometimes was successful after a relatively short interim period of drumming on the new host, and in these cases a mean of 3 4 eggs on the average were deposited in *Ephestia* if host 'eggs' of type 1 released the drumming act, 2 7 eggs if *Bupalus* eggs did so, and 8 5 eggs if drumming was released by eggs of *Dendrolimus* (Table 2)

(3) *Ephestia* eggs were offered, on which the drumming act was performed At the moment that the drilling act was started a *Bupalus* egg attached to the top of a hair was placed before the parasite and it was forced to accept it for drilling and oviposition In four successful cases a mean number of 1 5 eggs was deposited in the apparent host (Table 2)

These preliminary experiments show that the drumming act is connected with the determination of the size of the host egg To give a complete analysis more experiments will have to be carried out Moreover, the biological significance of the phenomenon of laying a different mean number of eggs in hosts of various size will be examined Quednau[6] has suggested that in a large egg only a relatively high number of parasites can survive, because the adults cannot emerge when part of the fluid contents of the host are left Our preliminary observations do not indicate this, but suggest that the mean number of eggs deposited in a definite species of host gives rise to the maximum number of the offspring which can be produced in that particular host egg, taking into consideration both the number of parasites emerging and their fecundity

MICROBIOLOGY

Hybridization of Homothallic Yeasts by Chen's Technique

IN the course of experiments performed in this laboratory it was found that spores of *Saccharomyces cerevisiae* var *ellipsoideus* were unable to germinate unless the medium contained glucose, fructose or mannose[1] Acetate agar (0 5 per cent sodium acetate in 2 per cent agar), or agar without added nutrients, are incapable of promoting germination On the contrary, vegetative cells are able to form microcolonies on 'nutrient-free' agar or on acetate agar, although the number of buds on this last medium is considerably smaller than on agar without additions The formation of microcolonies on solid 'nutrient-free' media is not at all surprising, and it has been studied in considerable detail in bacteria[2,3] The microcolonies formed under those conditions have larger numbers of cells than those formed on acetate agar, an observation which confirms the inhibitory effect of acetate on yeast growth reported in the literature[4,5]

The yeast strain used was isolated from fermenting grape juice and classified as *Saccharomyces cerevisiae* var *ellipsoideus* (strain 20 *SJ*) It is typically homothallic, and diploidization occurs very early in the life of the monosporic cultures The morphological events taking place during germination have been arbitrarily divided into the stages schematically represented in Fig 1 Diploidization usually occurs immediately after stage *F*, and two zygotes are formed In some cases, however, the four-celled stage *F* is followed by another haploid generation, but copulations occur immediately afterwards

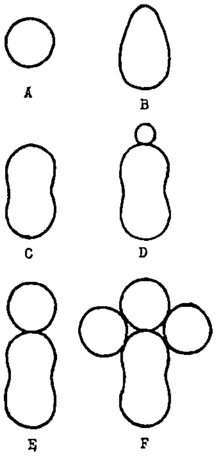

Fig 1

When spores were allowed to germinate in a suitable 'complete' medium (autolysed yeast-agar films in culture chambers) and, as soon as stage *C* was reached, they were transferred to acetate agar or to agar without additions by means of micromanipulation techniques, it was found that the germination process could continue and that the cells of the microcolonies thus obtained did not undergo diploidization through pairing These colonies were very small, particularly in the presence of acetate When spores which had attained stage *F* on 'complete' were transferred to acetate agar or to 'nutrient-free' agar, most of the microcolonies produced were constituted by haploid cells, except for a few colonies on 'nutrient-free' agar, which contained zygotes and diploid growth Acetate appeared, then, as a more efficient agent to prevent diploidization of the monosporic cultures Experiments performed with other strains of the same species in our laboratory seem to indicate that this phenomenon is of a rather general occurrence among the homothallic strains of *S cerevisiae*

The four cells of stage *F* could be used for pairing in genetic experiments However, with the homothallic strains of our laboratory we have found it very difficult to take apart the four cells without damaging them On the contrary, the cells from the microcolonies obtained according to the 'replacement' technique described here are rather loose and no difficulties are encountered during their isolation with the micromanipulator

Fig 2 shows the different stages of copulation between two haploid cells, one of which, the upper, has been picked from a microcolony formed on acetate The lower cell has been taken from a stable haploid strain obtained from *Saccharomyces aceti*[6] by spore isolation in this laboratory The true hybrid

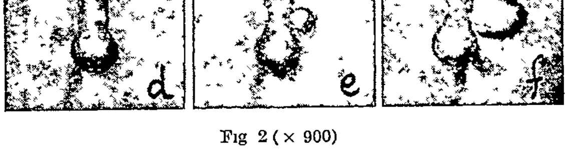

Fig 2 (× 900)

nature of this and other diploids obtained in a similar manner was checked by a study of the segregation of several genetic markers.

The method constitutes a handy extension of Chen's procedure[7] to homothallic strains. It allows the hybridization of those strains where diploidization occurs very soon after spore germination, in the cases when it is of interest to study the characteristics of the cultures derived from the same spores to be crossed. Obviously, since the growth on acetate agar or on agar without added nutrients is very limited in any event, it is necessary to transfer the remaining cells of the microcolonies to complete medium, as soon as the desired pairing has been successful.

Inhibition by Chloramphenicol of Protein Synthesis in the Cell-free System of a Chloramphenicol-resistant Strain of *Escherichia coli*

IN an investigation of the biochemical mechanism of chloramphenicol (CM) resistance in *Pseudomonas fluorescence*, Kuschner[1] reported that oxidation of succinate by intact cells of a CM-resistant strain was not affected by CM, although this reaction by the wild strain was moderately inhibited. On the other hand, the same reaction in cell-free systems of both strains was found to be equally sensitive to CM inhibition. From this result, he proposed that CM resistance in the resistant strain was due to decreased permeability against CM. Ramsey[2] investigated the action of CM on the formation of inducible enzymes by ultra-socially disrupted cell preparation of *Staphylococcus aureus*, and observed that the preparation from the CM-resistant strain still retained the resistance of intact cells so that changes in permeability was not the main source of resistance in this organism.

We investigated the mechanism of resistance with cell-free systems of protein synthesis from the CM-sensitive and resistant strains of *Escherichia coli B*. It was demonstrated that incorporation of amino-acid into protein by the preparation from resistant cells is almost equally sensitive to CM as in the case of sensitive cells. While this work was in progress, Yokota and Akiba[3], using the lysed protoplast system of CM-resistant *E. coli*, showed that the synthesis of β-galactosidase is sensitive to CM.

The strains used were *E. coli B*, and a CM-resistant strain developed by successive passages through media containing increasing concentration of CM. The concentrations of CM which were required to inhibit 50 per cent of growth in liquid media of the two strains were 0.4 μg per ml. for the wild and 300 μg per ml. for the resistant strain, respectively. Cells were grown on glucose-peptone medium for the wild strain or on that supplemented with 100 μg per ml. of CM for the cultivation of CM-resistant cells, under aeration, and gathered in the early logarithmic phase. The preparation of cell-free extract and amino-acid incorporation into protein was carried out according to Lamborg and Zamecnick[4] and Matsubara and Watanabe[5]. Cells were washed twice with 0.02 M *tris* buffer (*p*H 7.6) containing 0.008 M Mg^{++}, suspended in 2 vol. of the same buffer and disrupted by sonic oscillation (10 kc/s for 10 min). Large cell debris was removed by successive centrifugations (at 10,000*g*, 30,000*g* and 40,000*g*, each for 30 min). The 40,000*g* supernatant was further fractionated by centrifugation at 100,000*g* for 1 h to give supernatant (soluble fraction) and precipitate (ribosome fraction). For the experiment of amino-acid incorporation, ribosome fraction, soluble fraction, ^{14}C-labelled amino-acid mixture (acid hydrolysate of *Chlorella* protein supplied by the Institute of Applied Microbiology University of Tokyo). and co-factors required were mixed as described in the legend of Table 1 and incubated at 37° C for 20 min. The reaction was stopped by the addition of 5 ml. of 5 per cent trichloroacetic acid. The precipitate was washed once with 5 per cent trichloroacetic acid, treated once with hot acid (90° C for 15 min), dissolved and reprecipitated twice with 0.5 N sodium hydroxide and 5 per cent trichloroacetic acid, washed twice with ethanol/ether (3 : 1), and finally dissolved in 0.05 N sodium hydroxide. Radioactivity of aliquots were measured by a windowless, gas-flow counter. For the determination of the grade of inhibition by CM, serially diluted concentration of CM was added to the reaction mixture, and the incorporated radioactivity was compared with that of control without CM.

Table 1. INHIBITION BY CHLORAMPHENICOL ON THE AMINO-ACID INCORPORATION BY CELL FREE PREPARATIONS FROM CM-SENSITIVE AND RESISTANT STRAINS OF *E. coli B*

Strains	Sensitive		CM-resistant	
CM added	Total counts/min	% of inhibition by CM	Total counts/min	% of inhibition by CM
μg/ml				
0	522	0	1193	0
0.63	362	31	962	19
1.25	320	39	863	27
2.5	284	47	638	46
5	190	64	553	54
10	170	67	501	58
20	160	69	384	68
40	116	78	332	72

Each tube contained: supernatant fraction, 1 mg protein; ribosome fraction, 3 mg protein; $MgCl_2$, 8×10^{-3} M; KCl, 6×10^{-2} M; adenosine triphosphate, 0.5 μmoles; creatine phosphate, 6 μmoles; creatine kinase, 0.2 mg protein; *tris*, 2×10^{-2} M, *p*H 7.6; ^{14}C-amino-acid mixture 2×10^5 c.p.m.; with or without CM as indicated; total volume, 1.0 ml. Incubation, 20 min at 37° C.

As shown in Table 1, amino-acid incorporation by the cell-free systems of sensitive and resistant strains are almost equally inhibited by low concentration of CM. Thus, it can be deduced that in this resistant strain the process of protein synthesis is almost as sensitive as that of sensitive strain. Hence, it appears that CM is prevented from reaching its site of action by some sort of permeability barrier. Since, as reported previously[6], spheroplasts of resistant cells retain the most part of resistance, the role of cell wall does not seem to be important. The cell membrane or some inside structures will be responsible for the resistance.

It was consistently observed that the inhibition of amino-acid incorporation was not complete even in the presence of 40 μg per ml. of CM, where 20–30 per cent of incorporation continues to occur, whereas in intact cells the amount of the residual protein synthesis under CM inhibition is about 5 per cent. Since incorporation of amino-acid in this system is not inhibited by penicillin (40 μg per ml.), this may not be related to synthesis of cell wall substance. The nature of this residual incorporation remains to be ascertained.

Our results conflict with Ramsey's observation on CM resistant cells of *Staph. aureus.* Two possibilities may be considered. First, in the CM resistant strain of *Staph. aureus*, there may be a CM resistant pathway of protein synthesis which is not present in *E. coli.* Secondly, in the disrupted cell system used by Ramsey, some sort of permeability barrier may be still present.

A Selective-Diagnostic Medium for the Isolation of Pectinolytic Organisms in the Enterobacteriaceae

IN the family Enterobacteriaceae, the genus *Erwinia* has been divided into those which cause dry necroses, galls or wilts in plants, and those which produce the enzyme protopectinase and cause soft-rots in plants[1]. The latter group has been given the name *Pectobacterium* by Waldee[2].

The ability to liquefy pectate gels is of great importance in characterizing the soft-rot *Erwiniae* (Pectobacteria), and the technique devised by Paton[3] for preparing pectate gel has simplified the use of the test.

The isolation of soft-rot *Erwiniae* where large numbers of other bacteria (*Escherichia, Aerobacter, Pseudomonas, Bacillus,* etc.) are present may be somewhat difficult, and necessitate the examination of many types of colonies from primary plate media. The salicin medium of Noble and Graham[4] relies on the inhibiting action of a bile salt (sodium taurocholate) to prevent the growth of organisms other than those in the Enterobacteriaceae. The fermentation of the salicin is used as a diagnostic characteristic for recognizing possible soft-rot erwiniae. Colonies are slow to develop on this medium, which has only an ammonium salt as a nitrogen source.

It was felt that a solid plating medium combining the inhibitory power of bile salts and the diagnostic characteristic of pectate liquefaction, along with lactose or salicin fermentation, would prove of some value for isolating soft-rot *Erwiniae* from material heavily contaminated with other types of bacteria.

The following medium was devised:

Basal layer

McConkey agar granules ('Oxoid *C.M.*7')	5·2 g
Calcium chloride	0·4 g

These were dissolved with boiling in 75 ml. distilled water. The medium was autoclaved at 10 lb. pressure for 10 min, cooled and pipetted in 15 ml. amounts into sterile Petri plates.

Pectate layer

Sodium polypectate ('Exchange' brand)	2 g

This was suspended in 6 ml. of ethanol. 0·1 g of ethylenediamine tetraacetic acid (disodium salt) was dissolved in 100 ml. of distilled water, and this solution was added to the pectate suspension to a final volume of 100 ml. This medium was adjusted to *p*H 7·4, autoclaved at 10 lb. pressure for 10 min, and after cooling to about 55° C, was pipetted in 5-ml. amounts on to the cold, gelled McConkey agar base in the Petri plates.

The pectate layer set in a few minutes, and was ready for streaking after overnight drying at 37° C.

After 48 h incubation at 25° C, *Erwinia*, fermenting lactose, develops as red colonies in shallow pits formed from the liquefaction of the pectate. *Escherichia, Aerobacter* and other lactose fermenting, non-pectate liquefying bacteria appear as red colonies with no surrounding pit in the medium. Non-lactose fermenting bacteria produce yellow or orange colonies.

Salicin could be used instead of lactose in the basal layer where the type of *Erwinia* and/or the types of contaminating bacteria indicated its use. Its use would, however, involve the preparation of McConkey agar from its basic constituents.

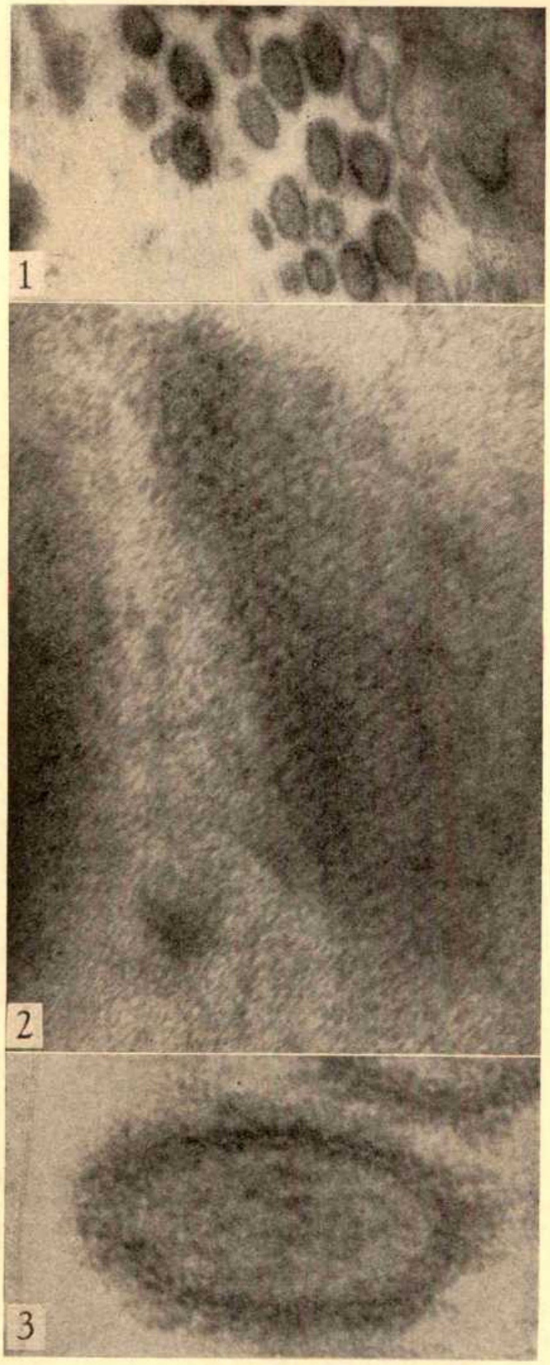
CYTOLOGY

An Electron Microscopic Demonstration of a Surface Pattern on the Plasma Membrane of Sectioned Intestinal Epithelium after Saponin Treatment

A TRANSVERSE section of the plasma membrane, after osmium or permanganate fixation, appears in electron micrographs as a triple-layered structure, about 8 mμ thick, composed of two outer opaque layers separated by a clear layer[1]. This unit membrane appears to be universal for all higher animal and plant cells and has been considered to represent the protein-lipid-protein molecular model as originally proposed for the plasma membrane by Danielli and Davson[2]. Until the recent report by Dourmashkin, Dougherty and Harris[3], little electron microscopic evidence had been produced to suggest heterogeneity on the plane surface of the plasma membrane. These authors demonstrated, however, that *in vitro* saponin treatment produced hexagonally arranged pits or holes in isolated membranes from erythrocytes, liver cells, Rous sarcoma cells and virus particles. The pits were seen in isolated membranes spread on grids after negative staining, and they



Figs. 1–3. 1, Electron micrograph of the brush border from the jejunum of a rat after exposure to 0·1 per cent saponin for 15 min (× 50,000). 2, An enlargement of the tangentially sectioned membrane from Fig. 1 (× 320,000). 3, A transverse section of a single microvillus (× 320,000)

state that they were unable to demonstrate these structures in sections of similarly treated liver cell membranes.

Intestinal epithelium is a convenient system for examining the *in vivo* effect of saponin since it can be injected into the lumen and the brush border presents a large area of regularly arranged membrane. Under 'Nembutal' anæsthesia, rats' jejunum was mildly distended with 0·1 per cent aqueous saponin, the intestine returned to the abdomen and later fixed by filling the lumen with Dalton's chrome-osmium fixative. The intestinal wall was dehydrated in absolute ethanol, embedded in 'Araldite' and the sections stained with 1 per cent potassium permanganate before examination in an A.E.I. *E.M.*6 microscope. After 15-min exposure to the 0·1 per cent saponin, the lumen contains cellular debris and the cells on the apices of the villi are necrotic but the crypts of Lieberkuhn, sub-mucosal and muscle coats appear unaffected. Hence along the sides of the villi a gradation from well-preserved cells to mere remnants of membrane and brush border can be studied. Fig. 1 shows an oblique section of the brush border just below the level of necrosis; in the lumen, on the left, a portion of membrane lies in the plane of section. At higher magnification (Fig. 2) this piece of membrane is seen to be covered with small clear rings; most of these possess dark centres and, in places, they are packed into a hexagonal pattern. The diameters of the rings cannot be measured, but the centre-to-centre spacing of 10–12 mμ is compatible with the 14–16 mμ separation reported in unfixed isolated membranes[3]. The relatively critical concentration of saponin required to produce these pits *in vitro*, coupled with the difficulty in obtaining true tangential sections, presumably account for the infrequent observation of the hexagonal pattern, but isolated rings on oblique membranes are often seen.

Unfortunately, tangential sections do not indicate whether these rings represent holes or pits. In transverse sections of the membrane the spacing of the rings is such that two or three layers will be superimposed even in a thin (20 mμ) section. Nevertheless, in such transverse sections (Fig. 3) definite discontinuities in the triple-unit plasma membrane are seen, these are not observed in control specimens and they have a width similar to the diameter of the rings. This observation could be due to linear discontinuities in a weakened saponin-treated membrane and would not seem sufficient evidence to conclude that the rings represent true holes in the plasma membrane.

Cytological Estimation of the Proportion of Proliferating Donor Cells during Graft-versus-Host Disease in F_1 Hybrid Mice infected with Parental Spleen Cells

Previous work has indicated that during graft-versus-host disease in mice, donor elements constitute only a small proportion of the cellular proliferation in the spleen of the hosts[1–3]. The fate of transplanted homologous cells has been examined experimentally by methods involving discriminant spleen assays of immunologically competent cells[1,3], estimation of humoral antibodies following transplantation of spleen cells hyperimmunized against sheep red cells[4] and more directly by chromosome analysis of all dividing cells[2,5].

Although in radiation chimæras the grafted cells react immunologically against the host, the reaction

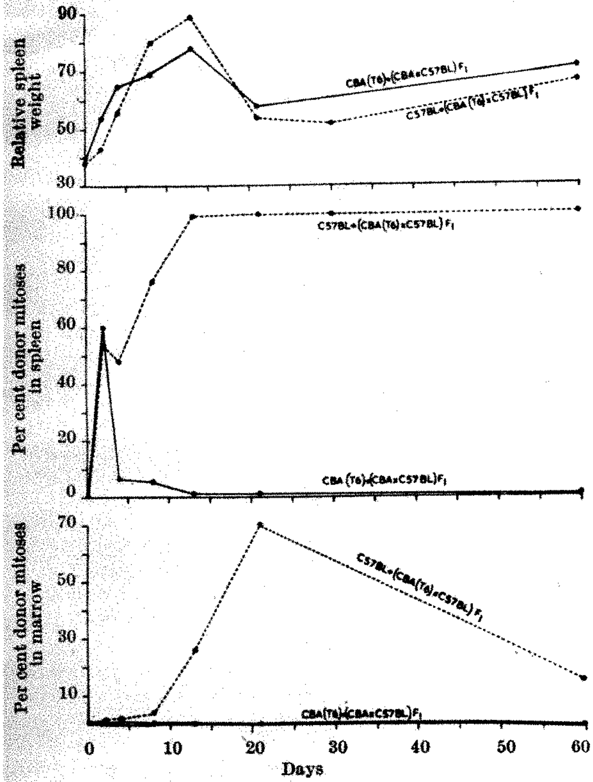

Fig. 1

is complicated by a number of factors including the after-effects of irradiation and some immunological reactivity of the host tissues. In order to obviate any potential host-versus-graft reaction, the response was examined in F_1 hybrid animals injected with cells from one or other of the parent strains against which the recipients are immunologically defenceless. Howard, Michie and Simonsen[6] studied the graft-versus-host reaction of this type in two different strain-combinations of mice by the discriminant spleen assay. They found that the greater part of the cellular proliferation in the spleen was of host origin, the number of immunologically active donor cells diminishing from about 19·5 per cent on the first day after injection. In the strains examined, Gorer and Boyse[7] believed that death of donor cells occurs, while Simonsen's[8] views are that with certain strain combinations a minority of the cells survive and become specifically tolerant to host antigens.

In the present work a cytological analysis of dividing cells in the spleen and marrow was carried out during graft-versus-host disease in (*CBA* × *C57*/*BL*)F_1 hybrid mice injected intravenously with 100 million of one or other of the parental strain spleen cells. By using mice with marker chromosomes[9] and making chromosome preparations by a modification of the drying technique as described by Fox and Zeiss[10] a simple and reliable method of tracing and quantitatively estimating proliferating donor cells was made available when either the host or donor animals were labelled with these markers. *CBA*(*T6*) mice were used; they are isogenic with regard to histocompatibility antigens with *CBA* animals, but their cells can be recognized by the chromosome markers, each nucleus containing two distinct short chromosomes (or one short chromosome in the F_1 hybrid). The proportion of donor to host dividing cells was determined in the spleen and bone marrow and the findings were correlated with the degree of graft-versus-host reaction as judged by the relative spleen weight.

Fig. 1 summarizes the results obtained from chromosome examination of spleens and bone marrow of 61 mice. The animals were killed 2, 4, 8, 13, 21, 30 and 60 days after injection, and approximately 300 mitoses were analysed at each stage in both spleen and bone marrow preparations.

When *CBA*(*T6*) spleen cells were injected intravenously into (*CBA* × *C57 BL*)F_1 hybrids, the response in the spleen could be divided into three consecutive phases: (1) an initial short-lived but tremendous burst of donor cell proliferation when the donor cells formed the majority of the dividing cells; (2) a more protracted rise of host mitotic activity resulting in splenomegaly; (3) a final period when donor mitotic activity was constant but remained in a minority.

There was a similar early burst of donor cell mitotic activity in the spleen following intravenous injection of *C57 BL* spleen cells into the F_1 hybrid (in this case the host cells carried the chromosome markers). No subsequent decline in the proportion of donor cells was observed, as when *CBA* cells were injected. On the contrary, a continued increase occurred so that by the thirteenth day, when spleen enlargement was maximal, all mitoses examined were of donor origin. No host cell mitoses could afterwards be found in the spleen of these animals, examination being carried out up to the sixtieth day after injection. One animal died on the forty-third day from graft-versus-host disease (loss of weight, diarrhœa and splenic atrophy).

The pattern of donor cell mitotic activity in the marrow was unlike that found in the spleen. No initial burst of donor cell activity was found when *CBA* spleen cells were injected. The highest proportion of donor cells occurred on the second day (0·5 per cent), and no donor mitoses could be demonstrated after the fourth day. Following *C57 BL* spleen cell injection, the proportion of donor cells increased gradually to the eighth day and then more rapidly, so that by the twenty-first day 70 per cent were of donor origin. By the sixtieth day dividing donor cells contributed 16 per cent of the mitoses in the bone marrow.

I thank Prof. M. F. A. Woodruff for his help and Dr. J. G. Howard and Dr. Donald Michie for their criticisms. The work was carried out during the tenure of a clinical research fellowship from the Medical Research Council.

GENETICS

Autosomal Recessive White-eyed Mutation in *Muscina stabulans* (Fall.)

PATERSON[1] has described a sex-linked and sex-limited white-eyed mutant in *Muscina stabulans* (Fall.). This communication reports a white-eyed mutation in the same species which involves a different mode of inheritance.

In the autumn of 1959, a normal female, sole survivor of a second laboratory generation of a strain trapped in Chicago, produced two broods (F_1) containing 33 white-eyed flies and 98 wild-type. The mutation appeared in both sexes (15 ♂, 18 ♀). Mass breeding of the mutants failed initially due to deposition of sterile eggs. After fertile eggs were laid, larval and pupal development were found to be normal with respect to rate and general behaviour. A possible defect in the F_1 mutant males is suggested by the following. The cross, mutant male × normal female produced only sterile eggs, whereas the reverse cross was productive. Appearance of the testes of the male was normal, but no microscopic examination was made. There was also evidence of reduced male longevity in the original broods. For example, 87 per cent of F_1 males were dead after 26 days, compared with 43 per cent of the females; whereas the per cent mortality of the F_2 generation after 26 days was: ♂, 53; ♀, 55. Other effects in the mutants were tremors in adults of both sexes and differences in pigmentation of the testes and Malpighian tubes. To examine these latter features, dissections were made of 2-week-old flies subsisting on meat, sugar and water. The results are summarized in Table 1. White-eyed flies produced unpigmented Malpighian tubes but their testes contained some pigment. Flies with intermediate eye colours, described here, varied from white-eyed to wild-type pigmentation. Paterson mentions no additional pigmental effects in his white-eyed *M. stabulans*; but the same sex-linked, sex-limited mutation is associated with normally pigmented testes and Malpighian tubes in *Calliphora erythrocephala* (= *vicina*)[2]. An autosomal recessive gene for white eyes produces colourless Malpighian tubes in *Lucilia cuprina*[3].

Table 1. PIGMENTATION IN VARIOUS EYE-COLOUR PHENOTYPES OF *Muscina stabulans*

Eye colour	Malpighian tubules	Testes
Wild-type	yellow	rust*
White	white	light orange
Yellow	light yellow or white	rust*
Ruby	yellow*	light orange

*Normal for the species

The F_2 progeny contained individuals with white eyes and various intergrading shades of buff, lemon, peach, cherry and ruby. Flies of the first 3 intergrades (yellow) were mass-bred together for 2 generations, as were those of the last 2 intergrades (ruby). Both groups produced white-, yellow-, ruby-, and wild-type flies. It became increasingly difficult after two generations to distinguish between the two intermediate groups; they were therefore combined and mass-bred. After 4 generations, the numbers of each type produced by the intermediate group were: white—87 ♂, 87 ♀; intermediate—684 ♂, 714 ♀; wild-type—119 ♂, 160 ♀. The totals after 4 generations of wild-type, mass-inbreeding were: white—13 ♂, 11 ♀; intermediate—64 ♂, 85 ♀; wild-type—119 ♂, 132 ♀. Comparison with other species shows that yellow-eyed *Phormia regina*[4] and *Callitroga macellaria*[5] breed true but *Musca domestica* does not[6]. Mass breeding of F_2 white-eyed flies produced the following F_3 progeny: white-eye—53 ♂, 40 ♀; yellow-eye—8 ♂, 5 ♀. Mass inbreeding of white-eye F_3 produced only white eyes in the following and 12 subsequent generations. As these flies aged, the white eye became slightly suffused with pink.

In June 1960, I sent by air pupæ of each type to Rome in order to continue this work at the Istituto Superiore di Sanità. The flies emerged but failed to breed and on my arrival all were dead. In the meantime, the colonies in Chicago began to fail and were lost after a few months. The observations recorded here are necessarily preliminary but the evidence presents a noteworthy difference in the mode of inheritance of the white-eyed mutation from that previously reported for this species. It indicates the existence in this fly of recessive autosomal loci acting independently of the sex-linked, sex-limited factor described by Tate and Paterson. So far as I am aware, this is the first such case reported in muscoid Diptera.

The occurrence of intergradations in eye colour of the intermediates may be a nutritional effect brought about by the limited availability of tryptophan derivatives in the larval diet. Ward and Hammen[7] have shown that some genotypic green-eyed houseflies develop pink eyes if reared in the presence of wild-type larvæ or their products. My intermediates are not true-breeding, and wild-type larvæ develop from the same egg-batches and in the same larval medium as the mutants. Under these conditions intermediate larvæ probably utilize limited amounts of precursors excreted by the wild-type, which the white-eyed larvæ are unable to do.

Inherited Variants in the Transferrins and Conalbumins of the Chicken

PREVIOUS electrophoretic studies of the serum proteins of the chicken have utilized moving boundary[1-5], paper[6,7], or starch-gel[8,9] techniques, the latter with 'continuous' borate buffer. Differences between individual sera were reported dependent variously on sex[1,2,6], onset of maturity and egg-laying[4,7,8], treatment with sex hormones[4,6], or stage of embryonic development[3,5,7,9]; but no inherited differences were found. Using horizontal starch-gel electrophoresis in the Poulik[10] discontinuous buffer system, both Lush[11] and ourselves have obtained considerably improved resolution of the zones. The former[11] confirmed and extended previous knowledge of variation dependent on sex and egg-laying, but did not find inherited variation among the sera of 66

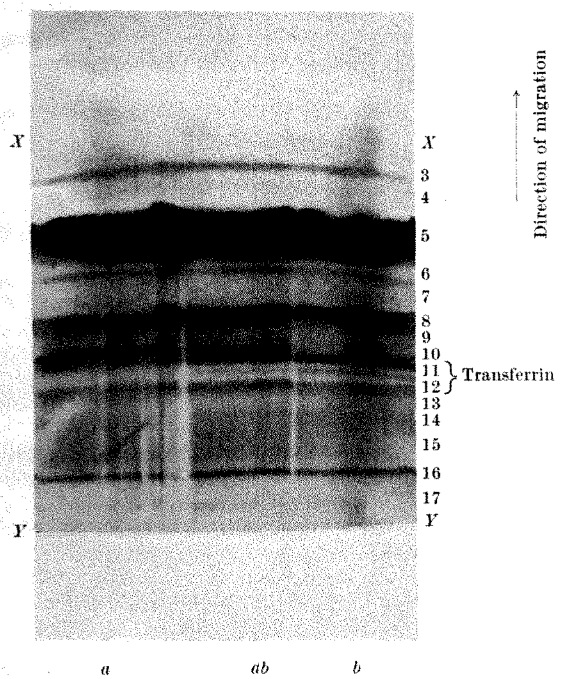

Fig. 1. Starch-gel electrophoresis of cock sera, showing the three transferrin types. Y—Y marks the position of insertion of the samples, and X—X the position of the brown line at the end of the run

chickens of various breeds. We have found inherited variation on one breed out of several studied, and have also found parallel inherited variation in egg-white protein.

In order to avoid possible confusion owing to the known variation dependent on egg-laying, most of our early work was carried out with cock sera. They were all subjected to electrophoresis separately at Stock and at Cambridge, under slightly differing conditions (Stock: 4¼ hr. at a field strength of 7 m.amp./cm.^{2} in a modified Poulik buffer system using lithium hydroxide instead of sodium hydroxide; Cambridge: 4 hr., 4 m.amp./cm.^{2} in the original[10] Poulik system) and our account is based on excellent agreement between the two sets of results.

The most frequent type obtained, with 14 distinguishable bands, is shown as type *b* in Fig. 1. Occasionally, under the most favourable conditions, 15 bands can be distinguished in male sera, and these are numbered 3–17 in type *a*, Fig. 1. (The major difference between types *a* and *b*, an inherited one, is described later.) More often band 9 is obscured by band 8, as in type *b*, Fig. 1. Band 2 occurs only in laying females and band 1 only at the onset of lay[11], while band 8 is absent in females during laying so that band 9 is easily visible. Other differences associated with sex and laying are matters of intensity and not of the presence or absence of whole bands. Type *b* was the only pattern found in the following breeds and strains, with the numbers tested in brackets.

White Leghorn: Reaseheath inbred lines, *C*(20), *I* (20), *R* (11) and *W* (12) at Cambridge; Cambridge *WICOB* outbred (25); Thornber strains, 1 (8) and 2 (12).

Black Leghorn: Thornber strain 3 (14).

Exchequer Leghorn: Thornber strain 4 (9).

Rhode Island Red: Thornber strain 5 (36).

In a Light Sussex strain (Thornber 6) three distinctly different patterns were seen. The differences involved bands 11 and 12. In the typical form (*b*) these consisted of a faster-migrating strong band (No. 11, Fig. 1) and a slower-migrating faint band (No. 12, Fig. 1). In the variant which we have called type *a* a similar pair of bands is seen, each migrating faster than its counterpart in type *b*, such that the slower, fainter band (No. 12) of type *a* coincides with the faster, stronger band (No. 11) of type *b*. In another variant (type *ab*) three bands are seen, corresponding in mobility with Nos. 11 and 12 of types *a* and *b* together. We have presumed this to be a heterozygous form (see later). The bands involved in this polymorphic variation were studied in autoradiographs (in collaboration with Dr. John Williams of the Department of Biochemistry, Cambridge, to whom our thanks are due), and were shown to bind iron, from which we conclude they are transferrins. Difficulty arose in interpreting the results of some of our electrophoretic studies, owing to the variability in position of a component (band 13) migrating close to transferrin. Its position relative to the transferrin bands could be faster, coincident, or slower, according to the conditions of electrophoresis, and in particular was dependent on the time in the whole run when the 'brown line'[10] passed through the transferrin region. The most satisfactory results were obtained by arranging the position of the insert, and the time of the run, such that band 13 consistently appeared well behind the transferrins, as in the gel illustrated in Fig. 1.

The simplest genetic hypothesis is that types *a* and *b* represent the products of alleles at a single locus, and *ab* of the heterozygote. Tests of sera of offspring from matings of tested parents gave results shown in Table 1, which are clearly in accord with the hypothesis. In conformation with a previously suggested system of nomenclature for mammalian transferrins[12], we propose the designations Tf^a and Tf^b for the

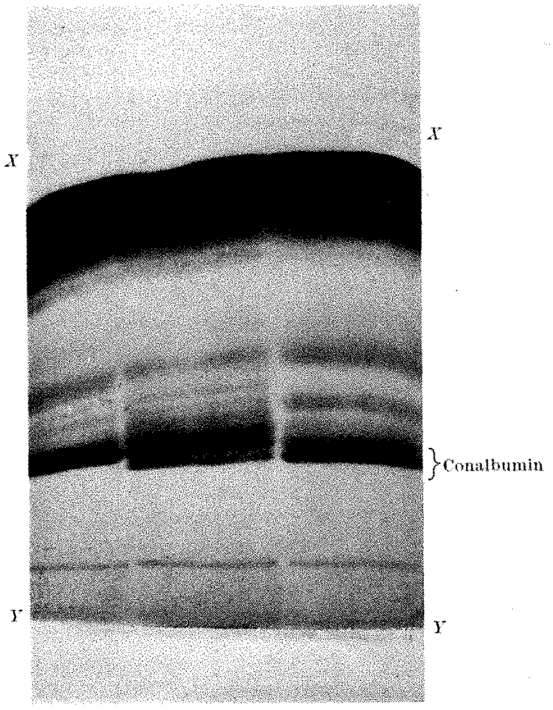

Fig. 2. Starch-gel electrophoresis of egg-white, showing the three conalbumin types. Y—Y marks the position of insertion of the samples, and X—X the position of the brown line at the end of the run

Table 1. SEGREGATION OF TRANSFERRIN TYPES AMONG OFFSPRING OF TESTED MATINGS

Mating type	No. of matings	Offspring *a*	Offspring *ab*	Offspring *b*	Total	Test for single locus d.f.	Test for single locus χ^2
a × *a*	4	38	0	0	38	—	—
a × *ab* *ab* × *a*	4	24	28	0	52	1	0·308
a × *b*	3	0	20	0	20	—	—
ab × *ab*	5	14	20	12	46	2	1·015
ab × *b* *b* × *ab*	5	0	26	34	60	1	0·533
b × *b*	4	0	0	45	45	—	—

alleles, and Tf-*a*, Tf-*ab* and Tf-*b* for the three phenotypes.

Williams[13] obtained evidence that chicken serum transferrin and egg-white conalbumin are glycoproteins, which have the same amino-acid sequence, but which differ in their carbohydrate moiety, causing a difference in their electrophoretic mobilities. We thus anticipated finding genetic variation in conalbumins parallel with that in transferrins. Electrophoresis of egg-white from hens of the three transferrin phenotypes, carried out under the same conditions as for sera, is shown in Fig. 2. The conalbumins are the heavily staining bands corresponding with bands 16 and 17 of Lush[14]. (The other variation in Fig. 2 involves Lush's locus III.) The variation in conalbumins, parallels that in the transferrins, the *a* transferrin type having two faster-migrating conalbumin bands, the *b* type two slower bands, and the *ab* type three bands, with the slow band of conalbumin *a* and the fast band of *b* in the same position. In each type the faster band is less intense than the slower.

We have tested eggs from 3 type *a*, 12 *ab* and 23 *b* hens, and in every case the conalbumins showed the corresponding bands, as already described.

VIROLOGY

A Sensitive and Precise Plaque Assay for Herpes Virus

Two techniques are at present available for the plaque assay of animal viruses. The most widely used involves the infection of monolayers of susceptible cells[1]: this method has been successfully applied to herpes virus by a number of authors using various cell systems[2–7]. The second technique, which has certain advantages over the monolayer method, uses agar-cell suspensions[8]: this method does not function satisfactorily with herpes virus in the cell systems tested (cf. ref. 3).

A method is described here which involves some features of both these techniques. The cells are infected in suspension and plated out to form monolayers in which plaques eventually appear. Variables affecting the production of plaques have been examined and the following procedure gives the optimal conditions for the assay.

Monodispersed cell suspensions are produced from monolayers by the action of a 0·02 per cent versene solution in phosphate-buffered saline or of a 0·05 per cent solution of trypsin in the 0·02 per cent versene solution. The cells are washed twice in Eagle's medium containing 10 per cent tryptose phosphate broth (Difco) and 10 per cent calf serum (ETC). Aliquots of the cells suspended in ETC containing 4 *n* million cells (where *n* is the number of 60-mm. assay plates required) are then centrifuged and the pellet of cells resuspended in *n* c.c. of an appropriate virus dilution in ETC. This cell-virus suspension is shaken at 37° C. for 20 min., when a further 4 *n* c.c. of ETC is added and 5 c.c. aliquots of the suspension plated into *n* 60-mm. Petri dishes. These are then incubated in a humidified atmosphere of 5 per cent carbon dioxide in air at 37° C. Secondary plaque formation is prevented by adding 5 c.c. per plate of an antibody containing medium, that is, Eagle's medium containing 10 per cent tryptose phosphate broth and 10 per cent pooled human serum, within 4–18 hr. after infection. Inhibition of secondary plaques can also be achieved by adding Eagle's medium containing carboxymethyl cellulose instead of ETC after the 20-min. adsorption period. This medium is prepared by adding 15 c.c. of a 5 per cent w/v solution of the sodium salt of carboxymethyl cellulose (L. Light and Co.) in water and 10 c.c. of calf serum to 75 c.c. of Eagle's medium (1·3 times normal strength). In this procedure, care must be taken not to move the assay plates during incubation.

Plaques 1–2 mm. in diameter are produced in 2–3 days, the time for maximum production of plaques depending on the type of cell infected. Plates are fixed with formol/saline, stained with Leishman's stain, dried and plaques counted using a hand lens (×4). The technique has been successfully applied with herpes virus (strain *HFEM*) to a line of HeLa cells adapted to calf serum; to a strain of baby hamster kidney cells, *BHK*21 clone *C*13 (ref. 9); to whole chick embryo cultures and to whole mouse embryo cultures.

The method has the advantages over present plaque assay methods of requiring only a short adsorption period and of producing the maximal number of plaques relatively quickly. A demonstration of the validity of this technique as an assay for the virus is seen in Fig. 1, where a linear dose response relationship exists over a wide range of plaque counts.

Table 1. COMPARISON OF PLAQUE AND POCK TITRES

Cells used	Plaque titre/ml.	Pock titre/ml.	Plaque/pock
HeLa	$7{\cdot}7 \times 10^7$	$1{\cdot}9 \times 10^7$	4·1
HeLa	$1{\cdot}9 \times 10^9$	$8{\cdot}0 \times 10^8$	2·5
HeLa	$5{\cdot}6 \times 10^8$	$1{\cdot}6 \times 10^8$	3·5
*BHK*21/*C*13	$4{\cdot}5 \times 10^{10}$	$1{\cdot}8 \times 10^{10}$	2·5
*BHK*21/*C*13	$4{\cdot}3 \times 10^9$	$1{\cdot}2 \times 10^9$	3·6
*BHK*21/*C*13	$1{\cdot}2 \times 10^9$	$5{\cdot}5 \times 10^8$	2·2
*BHK*21/*C*13	$4{\cdot}3 \times 10^9$	$1{\cdot}1 \times 10^9$	3·9
*BHK*21/*C*13	$9{\cdot}1 \times 10^9$	$2{\cdot}0 \times 10^9$	4·6
Whole chick cultures	$1{\cdot}7 \times 10^9$	$1{\cdot}1 \times 10^9$	1·5
Whole mouse cultures	$4{\cdot}0 \times 10^8$	$1{\cdot}1 \times 10^9$	0·4

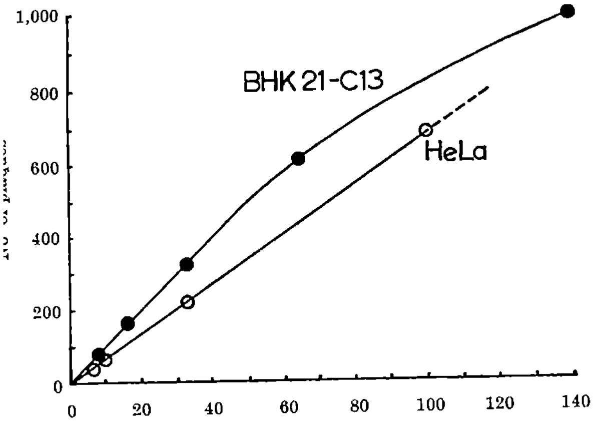

Fig 1 Relationship between plaque counts on HeLa and *BHK*21-*C*13 cells and relative virus concentration Different virus seeds were used in the two experiments

Further important advantages of the method are its reproducibility, sensitivity and precision The reproducibility is such that a given virus seed on assaying in *BHK*21-*C*13 cells in six different experiments making fresh dilutions to 10^{-7} each time shows a standard deviation of each measurement from the mean of 11 per cent Table 1 shows that with most cells tested the method is significantly more sensitive than the pock count on the chick chorioallantois The precision of the technique is illustrated in Table 2

Table 2 PLAQUE NUMBERS FROM REPLICATE DISHES

Cells used	Mean No of plaques per dish	Degrees of freedom	Variance	95 per cent fiducial limits of mean
*BHK*21/*C*13	12	15	12	1 8
*BHK*21/*C*13	429	11	311	11 4
*BHK*21/*C*13	119	5	78	9 4
*BHK*21/*C*13	55	12	71	5 0
HeLa	51	15	58	4 1
HeLa	263	15	304	9 3

The method has been shown to function successfully with other herpes strains and with vaccinia, pseudorabies and fowl plague viruses, secondary plaque formation being prevented by the addition of medium containing carboxymethyl cellulose

Inactivation of Naturally Occurring Variants of Tobacco Mosaic Virus with Nitrous Acid

ALTHOUGH there is general agreement that mutant strains of tobacco mosaic virus (TMV) may arise during oxidative de-amination of the ribonucleic acid by nitrous acid, this view has been held without conclusive evidence eliminating selection as a possible cause for the appearance of new strains Soon after Gierer and Mundry[1] announced the results of their experiments in which the mutagenesis of nitrous acid was implied, Bawden[2] pointed out that their results did not, in fact, exclude the possibility of selection, and despite Mundry's counter-claims[3], the issue has remained unsettled

Bawden based his argument for selection on the known competitive behaviour of strains of TMV For example, when two strains of TMV compete for the same limited number of infective sites, the extent of competition is found to be a function of both the ratio of the two strains to each other, and the total concentration of infectious units in the inoculum[4] Thus, at any one ratio, the extent of competition encountered by one strain in the presence of the other depends on the concentration If the starting TMV preparations in the nitrous acid experiment contained a small amount of a variant strain competitively inhibited by the predominant strain, inactivation could reduce the extent of competition observed simply by reducing the total concentration of infectious units If, in addition, the predominant strain were inactivated at a faster rate than the variant, an absolute rise in the number of variant infections is possible without the predominant strain mutating As an example, a differential dilution following ultra-violet irradiation of a mixture of two strains of TMV was observed to simulate closely the results of a nitrous acid experiment[4] A comparison of the data from the following two experiments will show how different the results of simple dilution can be from a differential dilution

A mixture of two competing TMV strains *U*1 and *VM*, was prepared The ratio and concentration of the strains were adjusted so that competition reduced the number of *U*1 lesions appearing to approximately 10 per cent of the controls In one case, the mixture was diluted and in the other samples were irradiated with ultra-violet light for different intervals of time before the mixtures were used as inocula The dilution and irradiation results are shown in Fig 1 It can be seen that dilution reduced the number of *U*1 lesions appearing in the mixture, but not as much as if no interference were encountered Nevertheless, this effect was small, compared with the large absolute rise in the number of *U*1 lesions observed following irradiation More than five times the number of *U*1 lesions were engendered by the mixture that was irradiated compared with the unirradiated control It had already been established that *U*1 and *VM* differed in their *in vitro* ultra-violet sensitivity[4] by factor 5 With this information, plus the quantitative data on competition, it was possible to estimate the reduction in competition expected following the ultra-violet irradiation This estimate compares favourably with the observed results

Since all strains of TMV tested so far compete with each other, it is likely that any variant detected would also compete with the parent strain In the circumstances, the question of mutagenesis, or selection, arising from nitrous acid treatment of TMV can be resolved only after the sensitivity to nitrous acid of the variant or mutant strain has been determined For this reason, Mundry's argument[3] that "   differences in interference-induced selection may be considered to be excluded if treated material is compared with untreated controls of the same infectivity   " is an inadequate control An experiment was therefore designed in which the possibility of selection in the TMV system was investigated directly

One thousand single lesions produced by *U*1 on *Nicotiana glutinosa* were transferred to individual tobacco plants (*Nicotiana tabacum*) When systemic symptoms were apparent the plants were classified, and any plant displaying marked variation from the type strain was separated In all, 15 variants (1 5 per cent) were recovered Fourteen produced much milder symptoms than the parent common strain One was highly necrotic, causing severe stunting and distortion of the plant Transfers were made from each individual variant, and large amounts of each new strain were prepared All variants reproduced true to type Four of the milds and the one necrotic strain were selected for investigation

Infectivity dilution curves established that each variant had the same specific infectivity as the parent These five variants, the parent *U*1 strain, and two other related, but different TMV strains (*U*2 and *U*8) were then individually inactivated with nitrous acid utilizing the method described by Mundry and Gierer[1] Many kinetic investigations were made, the average results of which appear in Fig 2

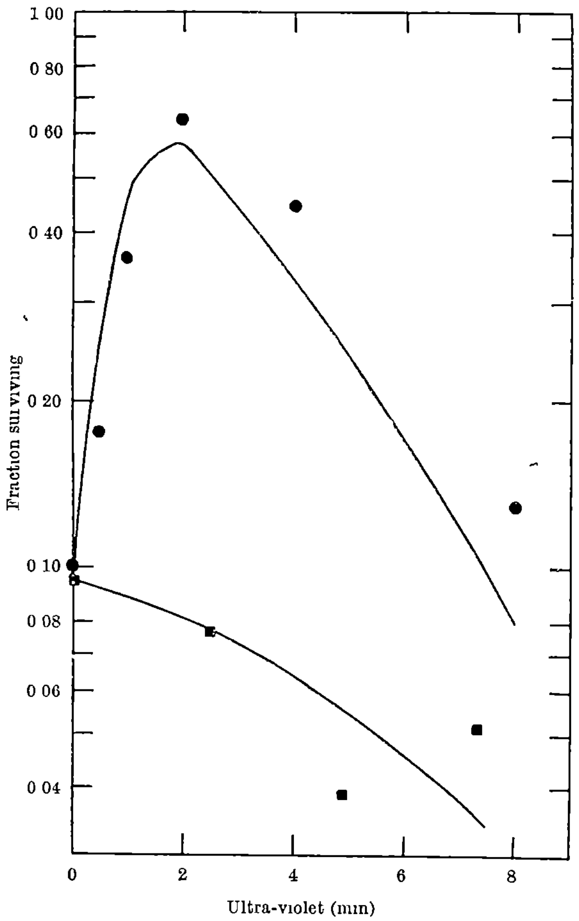

Fig 1 Competition between TMV strain *U*1 and *VM* (The irradiation data are taken from Rappaport and Wu, ref 5) *U*1 at 2 × 10^{-1} mg/ml was mixed with an equal volume of *VM* at 5 × 10^{-2} mg/ml One such mixture was irradiated *in vitro* with ultra violet light and then inoculated on leaves of *N glutinosa* The fraction of *U*1 lesions surviving appear in the upper curve Another mixture of *U*1 and *VM* as above was serially diluted in phosphate buffer before inoculation The fraction of *U*1 lesions observed in this case appears in the lower curve The dilution data are adjusted to fit the same abscissa as the irradiation data

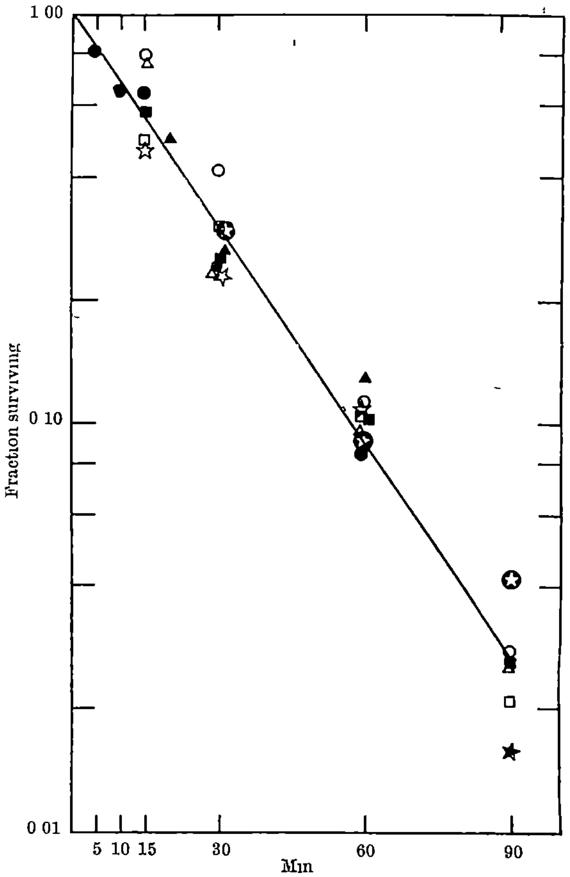

Fig 2 Nitrous acid inactivation of five variants, one parent and two other related TMV strains The data confirm those of Gierer and Mundry (ref 1)

Each TMV strain, regardless of its previous history, was inactivated by nitrous acid at essentially the same rate No significant differences were discernible This is in marked contrast to the different rates of inactivation of some of these strains by ultra-violet light Thus, inactivation of a mixture of two TMV strains with nitrous acid is equivalent to a simple dilution rather than a differential dilution Therefore, any absolute rise in the number of variants detected following a brief exposure to nitrous acid reflects induced qualitative changes in the starting material The results of Gierer and Mundry and of Siegel[6], who have investigated this phenomenon, all indicate that nitrous acid is mutagenic for TMV

FORTHCOMING EVENTS

Wednesday, September 12

Society of Environmental Engineers (in the Mechanical Engineering Department, Imperial College of Science and Technology, London, S W 7), at 6 p m —Mr Russell Lowe (U S A) "Structural Damping Allied to the Isolation of Electronic Equipment"

Thursday, September 13—Friday, September 14

Biochemical Society (in the Department of Agricultural Biochemistry, Institute of Rural Science, Penglais, Aberystwyth)—Colloquium on "Biochemistry of Plant Pigments" followed by original communications

Thursday, September 13—Friday, September 14

British Nuclear Energy Society (at the Institution of Civil Engineers, 1–7 Great George Street, London, S W 1)—Symposium on "The Advanced Gas-Cooled Reactor"

Friday, September 14

Society of Non-Destructive Examination (at the Institution of Mechanical Engineers, 1 Birdcage Walk, Westminster, London, S W 1), at 3 30 p m —Dr M McCraig "Magnetic Factors in Testing Materials"

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned

Lecturer (graduate or equivalent qualifications, and with sound industrial and teaching experience) in Electrical Engineering, to be responsible, under the Head of the Department of Engineering, for the development and supervision of electrical engineering courses and laboratories—The Principal, Aylesbury College of Further Education, County Offices, Aylesbury, Bucks (September 14)

Electronics Designer, Experimental Officer or Senior Experimental Officer grade (with a degree in physics or electrical engineering, or comparable qualification) in the Department of Chemistry, to collaborate with members of the teaching staff in designing and constructing electronic equipment to be used in research work in the Department—The Registrar, The University, Manchester 13 (September 15)

Hospital Biologist (with a university degree in physiology, biochemistry or zoology, or similar qualifications) in the Department of Chemical Pathology, for routine bioassay and chemical procedures mainly in the field of clinical endocrinology, research facilities also available—The Deputy Director, Vincent Square Laboratories of Westminster Hospital, 124 Vauxhall Bridge Road, London, S W 1 (September 15)

Research Fellow (preferably with a knowledge of many-electron atom theory and of computing) in Theoretical Chemistry, to work with Dr H O Pritchard on exact calculations for lithium and beryllium using the Atlas computer—The Registrar, The University, Manchester 13 (September 15)

Hargreaves Research Assistant (graduate in agriculture, agricultural science or science) in Agriculture, to do research over a period of three years on fertilizer placement in beet and potatoes—The Registrar, The University, Leeds 2 (September 17)

Research Student (graduate in zoology) in Zoology, to undertake research in relation to the ecology of the food consumed by salmonid fish—The Secretary, The University, Exeter (September 17)

Senior Research Officer (honours graduate in agriculture or science, with tropical experience or other evidence of appropriate research and administrative ability) at the Forest Products Station, Kade, University of Ghana, to accept professional and administrative responsibility for the running of the Station in consultation with a Committee of Management composed of members of the Faculty of Agriculture—The Registrar, University of Ghana, P O Box 25, Legon, Accra or The Assistant Registrar (Overseas), University of Ghana, 15 Gordon Square, London, W C 1 (September 17)

Senior Lecturer in Economics in the Faculty of Social Science, Queen's College—The Secretary of the University of St Andrews, Queen's College, Dundee (September 22)

Assistant Experimental Officer (graduate, drawing ability an advantage) in the Nematology Department, to work on the taxonomy of plant-parasitic nematodes—The Secretary, Rothamsted Experimental Station, Harpenden, Herts (September 24)

Bacteriologist, Scientific Officer or Senior Scientific Officer grade, at the Marine Laboratory, Aberdeen, to be responsible for statutory diagnosis of furunculosis and other diseases in salmonid fish, and to undertake research either in such diseases or in bacteriological aspects of marine productivity—The Establishment Officer, Department of Agriculture and Fisheries for Scotland, Room 73, St Andrew's House, Edinburgh 1 (September 24)

Lecturer or Assistant Lecturer in Bacteriology—The Registrar, The University, Leeds 2 (September 24)

Lecturer (graduate with a good honours degree) in Sociology at the University College of Cape Coast, Ghana—The Assistant Registrar (Overseas), University of Ghana, 15 Gordon Square, London, W C 1 (September 24)

Assistant Librarian (graduate with university library experience, preferably male, age 30–45), for general, including administrative, duties—The Goldsmith's Librarian, University of London Library, Senate House London, W C 1 (September 28)

Senior Lecturer (with an honours or higher degree in chemical engineering and with research and teaching or industrial experience) in Chemical Engineering at the University of Cape Town, South Africa—The Secretary, Association of Universities of the British Commonwealth, Marlborough House, Pall Mall, London, S W 1 (September 28)

Lecturer or Assistant Lecturer in Stability and Control of Aeroelasticity in the Department of Aeronautics and Astronautics—The Secretary and Registrar, The University, Southampton (September 29)

Physicist/Mineralogist (with a university honours degree in science, with adequate training in mathematics, physics and chemistry, preferably with postgraduate training to Ph D level or equivalent research qualifications in some field of X-ray studies) in the Mineralogy Section, Division of Soils, C S I R O , Adelaide, South Australia, to undertake research on soil problems by X-ray techniques —Mr P F Butler, Chief Scientific Liaison Officer, Australian Scientific Liaison Office, Africa House, Kingsway, London, W C 2, quoting Appointment No 270/246 (September 29)

Lecturer (with qualifications in either pure or applied mathematics) in Mathematics at the University of Canterbury, Christchurch, New Zealand, to engage in research in his own field or to assist with the work in the field of rocket ballistics already in progress in the mathematics department—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S W 1 (September 30)

Lecturer or Junior Lecturer in Social Anthropology at Rhodes University, Grahamstown, South Africa—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S W 1 (September 30)

Senior Lecturer and a Lecturer in the Department of Mathematics, University of the Witwatersrand, Johannesburg, South Africa —The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S W 1 (South Africa and London, September 30)

Senior Research Fellow (with Ph D or equivalent postgraduate research experience) in the Department of Zoology, Royal College, Nairobi, for work on the nature of the host/parasite relationships of Ixodid ticks—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W C 1 (September 30)

Lecturer in Philosophy at the University of Melbourne, Australia —The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S W 1 (Australia and London, October 15)

Lecturer in Physical Chemistry at the University or Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S W 1 (October 15)

Lecturer (with postgraduate qualifications and research interests in sensation and perception) in Psychology at the University of Auckland, New Zealand—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S W 1 (October 15)

Senior Lecturer in Social Anthropology at the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S W 1 (October 15)

Physicist (with an honours degree in physics, and preferably with a special interest and aptitude in electronics) in the Physics Section of the Anti-Cancer Foundation, for work on problems arising from the application of ionizing radiation to the diagnosis and treatment of disease—The Secretary, The University of Adelaide Anti-Cancer Foundation, Adelaide, South Australia (November 1)

Bibliographic Assistant, to assist with literature search and abstracting in connexion with medical and scientific research—Prof A C Frazer, Department of Medical Biochemistry and Pharmacology, The University, Birmingham 15

Biochemist—(non-medical) for the Group Laboratory, Guildford —The Hospital Secretary, St Luke's Hospital, Guildford, Surrey

Biochemist (science graduate, preferably with an honours degree in chemistry) in the Chemical Pathology Department, for duties including routine investigations and participation in research—The Senior Consultant Pathologist, Queen Elizabeth Hospital for Children, Hackney Road, London, E 2

Chief Technician, to take charge of electronic medical workshop —The House Governor, The Hospital for Sick Children, Great Ormond Street, London, W C 1

Entomologist (Medical) (national of, and resident in, Great Britain or the Republic of Ireland, with an honours degree in Zoology, and preferably with postgraduate specialist experience in entomology) with the Government of Uganda, to work under the general direction of the Senior Entomologist (Medical) on the general problems of medical entomology and the control of vector borne diseases the duties will entail a great deal of field work involving considerable physical hardship—The Director of Recruitment, Department of Technical Co-operation, 3 Sanctuary Buildings, Great Smith Street, London, S W 1, quoting RC 205/153/018

Principal Biochemist (male, with a university science degree, associate or graduate member of the Royal Institute of Chemistry), for duty at H M Prison, Wormwood Scrubs, London—Establishment Officer (JB 652), Prison Commission, Horseferry House, Dean Ryle Street, London, S W 1

Research Scholar or Assistant (with a degree or diploma in technology, and with an interest in the applications of computers) in the Computer Centre, to engage in a programme of research in methods of numerical analysis suitable for a medium-sized computer, the preparation of an Algol compiler or an approved data handling topic—The Academic Registrar, Loughborough College of Technology, Loughborough, Leics, quoting reference 21/G

Scientific Officer or Senior Scientific Officer (honours graduate in applied mathematics), to work on problems in rheology theory of plasticity, theory of elasticity and thermal stresses—Dr N F Astbury, Director of Research, The British Ceramic Research Association, Queen's Road, Penkhull, Stoke-on-Trent

Technician (with suitable qualifications and preferably with a knowledge of photography or tissue culture) to assist in chromosome research—Dr Martin Bodian, Department of Morbid Anatomy, Hospital for Sick Children, Great Ormond Street, London, W C 1

EMPLOYMENT OF SCIENTISTS AND TECHNOLOGISTS

WHEN the report on the *Long-Term Demand for Scientific Manpower* (which the Statistics Committee of the Advisory Council on Scientific Policy prepared at the request of the Council's Committee on Scientific Manpower) was published last autumn, the Committee's conclusion that by 1965 the supply and demand of such manpower should not be much out of balance and that thereafter a surplus might exist caused some concern (*Nature*, 192, 293, 1961) The assumptions and conclusions of the Committee were indeed questioned, notably in a debate in the House of Lords on November 15, but apart from the fact that, as the Committee itself points out, the balance is a statistical one and that supply and demand in individual disciplines cannot be so easily equated, the Committee on Scientific Manpower, in presenting the report, suggested that in the educational profession and in those disciplines which involve a high degree of mathematical skill the present shortage of scientific manpower is likely to continue for a long time

While as yet the assumptions which the Committee made regarding demand do not appear to have been seriously challenged, its assumption regarding supply is certainly rendered dubious by the Government's policy towards the universities It now appears unlikely that the universities will be able to achieve by 1971 the expansion figure of 170,000 assumed by the Statistics Committee, and, even if there were no similar check to expansion of the colleges of technology and similar institutions, it is now problematical whether it will be possible to count on the 147,300 technologists and 107,700 scientists at the beginning of 1965–69, 149,300 scientists and 196,000 technologists at the beginning of 1970–74, and 206,000 scientists and 257,500 technologists at the beginning of 1975–79 postulated in the report unless there is a very early change in Government policy The universities must be given the tools as well as the time to do the job, and the question of quality is of increasing importance Prof M Stacey, of the University of Birmingham, who believes that the demand for chemists will remain high, has recently given some impressive figures of the existing strain on the capacity of the universities, and although the universities are prepared to take as many more entrants as possible without lowering standards, they are determined not to relax these standards

The report from the Appointments Board of the University of Birmingham for 1961 * suggests, however, that in the meantime the point when the output of graduate scientists exceeds demand may be nearer than that forecast by the Statistics Committee The report does not indeed refer to an actual shortage of vacancies for scientists, though it comments that some technologists may have to be prepared to take staff positions rather than the more usual apprenticeships Furthermore, it expresses the hope that more technologists will turn to teaching, either in schools or in higher technical education Some firms, however, found in October that they had fewer vacancies than were expected in the previous spring, and the Scientific Civil Service, the Atomic Energy Authority and the Patent Office all reported fewer vacancies for chemists than in previous years Demand for specialists, such as petroleum production engineers, has markedly fallen in consequence of many oil companies cutting down on exploration Here the Appointments Board suggests that, as they meet stiffer competition, oil and chemical companies are re-examining the staff structure, with a resultant decrease in vacancies for chemical engineers, in any event for the present

Nevertheless, the report notes a marked interest in flexible and adaptable scientists who are good at languages and of acceptable personality, since these can easily find posts on the commercial side of any industry interested in exports or the Common Market The Board's general impression, however, is that there are both fewer inquiries for graduates than there were in the previous year and also few vacancies in the organizations seeking recruits A report for 1961 from the Appointments Committee of the University of Glasgow †, however, contains no evidence in support of this, and in respect of the Women's Section states definitely that there has been no falling off in the number of vacancies notified The report seems somewhat preoccupied with whether or not the graduates find employment in Scotland, and refers to a continuing shortage of engineers of good quality and the desirability of shortening the training period where possible

If it be judged that these reports from university appointments committees or boards support the conclusions of the Committee on Scientific Manpower which have been held in some quarters to be unduly optimistic, it should be remembered, first, that the Committee made numerous reservations which may or may not be operative It was fully aware, for example, that the requirements of the Atomic Energy Authority were likely to contract Secondly, it should be remembered that in the Committee's view the possibility of a balance or even a surplus should be welcomed It should facilitate a rational use of the scientific disciplines, and it should mean that at last the Nation has a supply of qualified manpower with a scientific training for management, administration and the professions generally, in addition to those who hitherto have been drawn normally into vocational employment

That the Committee on Scientific Manpower is right in thinking that it will be to the benefit of the

---

* University of Birmingham Annual Report of the Appointments Board for the year ending 31st December, 1961 Pp 6 (Birmingham University Appointments Board, 1962)

† University of Glasgow Appointments Committee Report for the year ended 31st December, 1961 Pp 20 (Glasgow University Appointments Committee, 1962)

Nation as an increasing proportion of those trained in specialized scientific disciplines find employment outside them is not to be doubted. Moreover, there is evidence in the Zuckerman Report on the management and control of research and development that that Committee also is thinking on the same lines (see *Nature*, **193**, 710, 1962). There are, however, two important points to be remembered if this situation arises. First, it will accentuate the need for some adjustments in the education of scientists and technologists, particularly in the direction of a broad and balanced education so as to encourage flexibility and avoid narrowness and rigidity.

The Committee on Scientific Manpower found some evidence that the universities are already thinking along such lines, and it is important that effective action should be taken before the expected surplus arises. On no account should the financial pressure which the Government has put on the universities be allowed to prevent such changes or developments. Secondly, however, and no less important, some changes are called for in the attitude of some of the professional associations.

It is clear from the Zuckerman Report and from what the Minister for Science has since said that changes are already contemplated in the Scientific Civil Service and the use made of scientists in the Government service which are both appropriate to the more effective use of trained manpower and in keeping with the situation visualized in the report on the *Long-term Demand for Scientific Manpower*. It follows that in such a situation it will not be so easy to equate supply and demand in terms of individual scientific disciplines. Demand must be interpreted with some elasticity as well as with judgment. Neither scientists nor technologists can expect to press for consideration for administrative appointments on equal terms with those qualified on other grounds and at the same time complain that their qualifications are wasted if they are expected to take up occupations in which the exercise of scientific skill as such is not a first requirement. Since the publication of the Zuckerman Report and the report on the *Long-term Demand for Scientific Manpower*, it is exactly this that some institutions and individual scientists seem inclined to do.

PROPERTIES AND STRUCTURE OF COAL

Coal. Typology—Chemistry—Physics—Constitution

By Prof. D. W. Van Krevelen. Pp. xviii+514. (Amsterdam: Elsevier Publishing Company; London: D. Van Nostrand Company, Ltd., 1961.) 100*s*.

IN 1957 *Coal Science*, by D. W. van Krevelen and J. Schuyer, was published. While in a sense the present book is a new edition of the earlier one, it is much broader in approach, and more mature as a result of the great advances made in the past five years. van Krevelen has taken sole responsibility for authorship. Much of the content of *Coal Science* will be found in *Coal*, and a good deal more besides, but the weaknesses noted in the former (see *Nature*, 181, 4, 1958) have largely been eliminated. The strong theme that runs through the book and its planned integration make for interesting reading. The author propounds detailed views on coal constitution that explain qualitatively many of its properties, but several unsolved features of coal structure remain, some common to the many "amorphous brown substances" found in Nature. The achievement of a more-or-less satisfactory model structure for coal does not yet rule out the possibility of related, yet different, structures superseding it.

A good balance within the limits of space (the book is half as long again as the previous one) is reached between the following main topics: occurrence and systematics, geology and metamorphism, physical structure (151 pages), chemical reactions (153 pages), physical properties (123 pages), and coal constitution including the mechanism of carbonization (49 pages). The book incorporates a topical selection of new information and omits some that has been superseded, and overcomes difficulties always experienced in a work of this type, for example, the correct place in which to describe X-ray diffraction studies. By selecting for Parts 2–4 the titles "Coal Chemistry", "Coal Physics" and "Coal Constitution", respectively, a logical classification of subject-matter has been combined with an integrated discussion of the evidence, from whatever source, concerning a given molecular feature.

Part 1 consists of a straightforward and authoritative account of coals: their distribution and nature, their classification, and theories of their formation in both geological and chemical terms. The composition, properties and technological functions of macerals are fully considered, and there is a systematic and greatly improved account of porosity, internal surface and molecular sieve properties. In Part 2, on the chemical properties, functional groups are first considered; a somewhat optimistic impression is given of the quantitative agreement reached on hydroxyl contents, and there is an occasional ambiguity about references to carbonyl groups which relates to differences in spectra between the conjugated and unconjugated forms. A considerably improved and extended account of solvent extraction is given. The complex literature on hydrogenolysis and on oxidation by various reagents is admirably clarified and condensed, though necessarily with the omission of many references. This is followed by an account of methods for the investigation of properties important in coke-making, and of a mathematical model describing the observed changes, the skilful use made of graphs greatly helps the exposition.

When discussing the physics of coal in Part 3, the author is especially interested in the deduction of chemical parameters from physical properties by means of additivity principles (statistical constitution analysis). The section on X-ray diffraction has been considerably expanded and constitutes a connected and critical discussion of the available results. Optical properties, ultra-violet and infra-red absorption spectra are given adequate treatment. There follows a good account of conclusions from the high-resolution nuclear magnetic resonance spectra of soluble fractions of coal and the broad-line nuclear magnetic resonance spectra of solid coals that were available; important papers on these topics have appeared since the book was written. Mechanical properties are considered from the physical point of view Constitutional evidence from heat of combustion (Table 21, 2 *et seq*) has been superseded by conclusions reached in a very recent paper Part 3 concludes with sections on thermal properties

Part 4, on coal constitution, is also closely concerned with statistical constitution analysis, for macromolecular substances of non-uniform chemical structure this, with other physical methods, is a necessary field of study, since classical chemical methods are limited in application and interpretation, at least in respect of skeletal structure The summing-up in terms of values of the statistical parameters is unexpectedly disappointing For example, values of carbon aromaticity are basic, and quantitative estimates concerning other features of the molecule are sensitive to variations in them, the values selected range, in the rank group 80–90 per cent carbon content, from 0 8 to nearly 0 9, and I would not be alone in considering a radically different range, 0 65–0 75, as most compatible with up-to-date evidence Some values of other parameters that have been shown since writing to be incorrect have unavoidably been included in the summing-up In general, the values quoted are largely based on indirect methods

The last two chapters in Part 4 are concerned with the interesting and imaginative work of the author and the late Prof Waterman on condensation products of aromatic compounds with radioactively-labelled formaldehyde With the aid of these model compounds, the coking properties and decomposition yields with coal can be much better understood

The book concludes with an interesting and useful 13-page appendix "Historical Development of Fundamental Coal Research" In effect, this includes an up-to-date directory of coal research

The book gains in clarity from the adoption of a critically selective approach to the literature It is impossible to refer in detail to all errors noted, but very few are serious, and misprints are of minor importance The index of 17 pages seems to be adequate The good features of layout in the earlier work, *Coal Science*, have been retained, and the style is eminently logical and readable

Coal will provide both those concerned with the use of coal and new recruits to the study of coal science with a firm basis of fact and an excellent critical introduction to present-day thought on the subject Production is excellent and the price moderate The book is strongly to be recommended

PROBLEMS OF BLOOD TRANSFUSION IN JAPAN

Proceedings of the Eighth Congress of the International Society of Blood Transfusion

Tokyo, September 12–15, 1960 Edited by L Hollander (Bibliotheca Haematologica, Fasc 13) Pp xiv + 546 (Basle and New York S Karger, 1962) 85 Swiss francs

THE first international congress of blood transfusion to be held in the Far East was held in Tokyo in September 1960 All but two of the 125 papers delivered at this Eighth Congress of the International Society of Blood Transfusion are now published *in extenso* in a single volume of 546 pages

One of the pleasing things about this volume is that it is prefaced by two charming songs, in Japanese and with an English translation, entitled "On Blood Transfusion", by Her Imperial Majesty, Empress Nagako In how many other instances, one wonders, have the published proceedings of a scientific congress been graced in such a heart-warming manner? Noteworthy also is the fact that the contributors adopted a suggestion made by the President of the Society that the longer papers read should not exceed 2,000 words, and the shorter papers 1,000 words, when prepared for publication In consequence, this volume is not only less bulky to handle than that of many other proceedings, but also the salient facts are more readily assimilated by the reader

It is disturbing to note that blood for transfusion is supplied in Japan almost entirely by professional donors, many of whom are so poor that they donate blood to the commercially run blood banks when they lose their jobs or are faced with some urgent pressing need to obtain money The fact of rapid repeated blood donations has led to a dangerous increase in the number of persons no longer acceptable as donors because of anæmia In 1959, for example, 45 per cent of persons offering their services as professional donors had to be rejected as unacceptable on health grounds In reporting on this problem, Dr Y Azuma states that the Japanese Red Cross Society has earnestly appealed to the public to create and support a voluntary blood donor system, but that the response in 1960 still fell far short of the requirements of the hospitals

The proceedings of this congress contain the views held in 1960 by leading authorities in every continent of the world on many aspects of immunohæmatology and transfusion The nine sectional sub-headings include the transfusion problems of extracorporeal circulation, new aspects of blood group serology, studies of the serum groups such as the haptoglobins and transferrins, the preservation of blood cells, and problems of transfusion reactions This volume contains, therefore, much of interest and value to all concerned with blood transfusion, and the editor, Dr L Hollander, and the publishers are to be congratulated on the high standard of production

VACUUM SCIENCE

Scientific Foundations of Vacuum Technique

By Saul Dushman Edited by J M Lafferty Second edition Pp xviii + 806 (New York and London John Wiley and Sons, Inc , 1962) 147*s*

SINCE 1949, when the first edition appeared, scientific workers all over the world have used "Dushman" as a valuable source-book However, the many advances of recent years have necessitated revision of this text Indeed, it highlights the rapid growth of vacuum science that, whereas the first edition was up to date, there is little or no mention in it of such recent innovations as the techniques of ultra-high vacuum, the getter-ion pumps Roots pumps, cryogenic pumping and alloy getters, while much progress has been made, for example, in studies of the interactions with solids of gases and gaseous ions of sorption and desorption, of diffusion processes, of measurements of partial pressure and of methods of detecting leaks All these topics and several more are included in this second edition

Dr. Dushman spent some thirty years compiling data on all aspects of the fundamentals of vacuum techniques. Now he has died it is unlikely that there is anywhere a successor with the breadth of knowledge and experience to undertake single-handed the writing of such a comprehensive treatise. Fortunately, the revision of this classic text has been entrusted to a team of eight specialists under the editorship of Dr. J. M. Lafferty, all of whom are members of the research staff of the General Electric Research Laboratory, Schenectady, N.Y., where Dushman was formerly assistant director. Sometimes books written by a team are badly co-ordinated and vexatious to the reader. Happily, this criticism certainly cannot be levelled at this second edition. The editor has most successfully woven the contributions of his team into the original text of Dushman to produce an up-to-date version which still retains the virtues of clear writing, comprehensiveness, full referencing and orderly development of the first edition.

As would be expected from its title, little appears in the book about applications. However, more detail of the scientific aspects of the design of very large vacuum plants would have been welcome. Again, stainless steel—increasingly used in modern ultra-high vacuum technology—receives little attention. Accounts of the kinetic theory are a little obscured by repetition of formulæ in various units, which would be preferably avoided by giving only basic formulæ and appropriate conversion tables.

But this is an excellent book. Dushman would have been proud of it. Like his own first edition, it will be indispensable for many years to come.

JOHN YARWOOD

MEASURING RADIOACTIVITY IN THE HUMAN BODY

Whole-Body Counting

Proceedings of the Symposium held by the International Atomic Energy Agency at the Neue Hofburg, Vienna, 12–16 June, 1961. Pp. viii+535. (Vienna: International Atomic Energy Agency; London: H.M. Stationery Office, 1962.) 60s.

THE whole-body counter is becoming increasingly important as a tool in health physics, to determine the amounts of radioactive materials which have entered the human body, generally as a result of an accident. It is, however, of greater interest than it appears to be at first sight; for example, its use can considerably extend many *in vivo* tracer experiments and the causes of obesity and similar disorders can be investigated by using it to determine the potassium-40 content of the body and hence the fat–lean ratio.

The earliest instruments of this type used ionization chambers, with low efficiency and poor geometry, but the development of the scintillation counter has brought tremendous advantages. Sodium iodide crystal counters have a higher γ-efficiency, and permit very good energy resolution for spectrometry but are restricted in size, thus limiting the solid angle. The geometry can be greatly improved by using plastic or liquid scintillators which are virtually unlimited in size, and a 4π counter using a liquid scintillator has already been constructed; these scintillators, however, have poor energy resolution.

Needless to say, the whole-body counter is very expensive, and considerable thought must be given to its siting, particularly in relation to the natural background and the type of shielding to be used. As a result, we are never likely to see large numbers of these instruments, but we should aim at making full use of those that are available, both for emergency measurements and for research.

Up to the present time, the method has been feasible only for measuring γ-emitters, but recent work in Sweden shows some promise of measuring body burdens of pure β-emitters by means of the associated bremsstrahlung. Another new development is the use of computer techniques for storage and processing of the data obtained in γ-spectrometry.

These are some of the problems discussed in detail in *Whole-Body Counting*. Those already in the field will probably be aware of progress elsewhere, but they will almost certainly find this book to be a useful survey. It will also be of considerable interest to health physicists, and to many users of radioisotopes who may well be surprised at the problems and possibilities of this type of instrument.

H. D. EVANS

ELECTRON MICROSCOPY

Traité de Microscopie Électronique

Sous la direction de Claude Magnan, avec la collaboration de Nina Carasso, Pierre Favard, Charles Fert, Angès Oberlin, Adrien Saulnier et Cyril Tchoubar. Tome 1. Pp. viii+1–650. Tome 2. Pp. viii+651–1301+33 planches. (Paris: Hermann, 1961.) 2 volumes 300 NF.

THINK of the most sumptuously produced scientific book you have ever seen—on any subject, animal, vegetable or mineral—double it, insert 33 full-page, glazed photographic prints, and you have the only complete treatise on electron microscopy in any language. The only comparable work has been *Electron Optics and the Electron Microscope* (1946) by a team colloquially known in the United States as 'We, the People'. But Zworykin, Morton, Ramberg, Hillier and Vance numbered only five and contained the subject within 760 pages, with very little on practical applications. The new French team of seven have need of almost twice the space, and at that, the electron optical part has been condensed into much less compass than the Americans allowed themselves; it is now the applications which have filled out to more than half the work.

Volume 1 describes the physical principles of electron microscopy and Volume 2 its applications. In addition to the basic optics, much attention is also directed to instrumentation—the theory of electron interaction with matter (including photography) as well as detailed descriptions of the many different types of electron microscope and their accessories. There are special chapters on the microscopy of solid surfaces, on electron interference effects and on electron diffraction, and on the aspects of crystallography with which these phenomena are concerned. Methods of specimen preparation are fully dealt with, and the first volume is completed by surveys of particle size and shape determinations and of physical and chemical transformations that can be followed by electron microscopy.

Volume 2 is devoted to the special preparation techniques for metallurgical and biological material, and surveys of the new knowledge which they have yielded about the very fine structure of biological tissues on one hand and of the texture of metals and alloys on the other The final chapter describes the role of electron microscopy in recent attempts at resolving the structural details of macromolecules, viruses and larger micro-organisms At the end of each chapter there is a list (usually very full) of references to original work, and the treatise has been given very extensive indexes by both author and subject

So far as random sampling could show, the treatment is comprehensive and thorough The French authors are all well known for their own contributions to the different fields on which they write, yet they take the wide view and do ample justice to work in other countries Inevitably, some aspects are stressed or neglected other than would have been done by a team under some other flag in Britain we should make more of metal physics, in the United States biological applications would loom even larger But the breadth and depth of electron microscopy are now so great that no country can be up on all the frontiers, and an editor has to pick the best team available Prof Magnan has done remarkably well in his task Anyone who has had to do with a composite work will know of the difficulty of collecting a team, ensuring reasonable uniformity of treatment and avoiding delay in publication This *Traité* appeared at the end of 1961, the references in most chapters are up to date to the end of 1960, and a few from 1961 are included

It is the only comprehensive, modern book on the subject and is certain to be the standard reference work for many years to come However, electron microscopy is still in rapid development, in techniques as well as applications, thin section-cutting in biology is barely ten years old, the preparation of electron-transparent films of metals only half this age Without in any way detracting from the magnificent achievement of our French colleagues, it may perhaps be queried whether so expensive a standard of production was really necessary Would it not have lowered the cost quite appreciably to use art paper only where needed for plates, and not for the whole text? We may be willing to pay £20 and more for an encyclopædia or art volume of permanent value, but no individual microscopist can face such a bill for a work that will need major revision within five years It is to be hoped, however, that libraries can be more open-handed, they may rest assured that the binding will stand up to the very heavy use any copy is certain to attract

V E COSSLETT

NEW METHODS FOR RAPID PUBLICATION

Proceedings of the Eighth Congress of the European Society of Hæmatology, Vienna, 1961

Part 1 Pp 1184 Part 2 Pp 1376 (Basel and New York S Karger, 1962) 172 Swiss francs the two parts

IT is usual to publish the Proceedings of international congresses, but during the past few years the advantages of this have been questioned The real benefit of congresses is to allow informal exchange of views between workers in allied fields who might otherwise never meet, for some participants can obtain a visa, or foreign exchange, only if their names appear on the programme as speakers It is difficult to exaggerate the value of these contacts, not only in the technical, but also in the social and political field, for, excepting the very carefully organized delegations which periodically appear, it is only during these congresses that ordinary workers from the two sides of the 'Iron Curtain' or the two sides of the Atlantic meet and talk freely

Although the reviews by famous speakers in plenary sessions are usually heard by a large audience and undergo simultaneous translation, original work by someone less well known is to be heard in a small lecture theatre by an audience of a dozen or so, half of whom have an imperfect understanding of the language used, and if the speaker is using a language not his own, the address may well be comprehensible to him alone This being so, publication of the Proceedings soon after the end of the congress is very desirable

However, in the past such publication has been slow, largely because very careful editing has been the rule, delays of a year or even eighteen months are usual, so that the authors of original work have already published it in the recognized journals—and indeed, it is quite impossible to give a detailed account of complicated experimental work in 1,000 words, which is as much as can be made comprehensible in the ten minutes the speakers are usually allowed

Messrs Karger have now cut the Gordian knot and produced the Proceedings only six months after the end of the eighth congress of the European Society of Hæmatology This feat has been accomplished by a radical re-organization of the editorial process—indeed, one might almost say by the abolition of the editor. Soon after the end of the Congress, all speakers received sheets of special paper on which to type the text of their contribution, after collation, these were photographically reduced on to offset plates and printed, special art paper being used wherever illustrations were required The results fully justify this departure from tradition, all the papers are reasonably legible, though some authors have submitted tables, graphs or line drawings so small that after reduction they are virtually illegible, should this process be used again this particular disadvantage may require special attention Those authors who use electrically operated typewriters have produced texts as legible as is type-set copy, but there are a few whose typists omitted the desirable cleansing of the type-face, with consequent reduction in legibility In fact, one of the most interesting things about these two volumes is the contrast in type-face, almost every type-face available on a typewriter is to be seen here, and one can see what a great increase in legibility has been obtained by using the new type-faces compared with the old and traditional styles, and how large a part is played by the spacing between letters

When 551 papers are contributed in 52 sections by about 800 authors, it is clear that they must represent a cross-section of present-day world opinion on the growing points of hæmatology, it is for this reason, rather than any single contribution, that one welcomes these volumes, even though at 285*s* they will be beyond the pocket of most individual contributors one would have hoped that at this price the publishers could have provided a proper binding instead of the thin card covering which they have used, but this is probably unavoidable with publication so quickly accomplished

G DISCOMBE

NATIONAL INSTITUTE FOR RESEARCH IN DAIRYING

GOLDEN JUBILEE

By Prof. R. G. BASKETT, O.B.E.

Director

FIFTY years ago, with the aid of a grant from the Development Fund, a Dairy Research Institute was established at the then University College, Reading. The income of the Institute was of the order of £2,000 per annum and there were two members of staff, R. Stenhouse Williams, a research bacteriologist in dairying, and John Golding, a research chemist in dairying. The Institute was accommodated in the attics and cellar of a dwelling-house near the College. These were small beginnings, but the initial lack of facilities was balanced by the clear vision and energy of Stenhouse Williams. As a medical man he was aware of the high nutritional value of milk in the human diet, but he was equally aware of the bad conditions in which milk was produced on the farm and handled during distribution. The older generation of dairy farmers and dairy scientists will remember the almost missionary zeal with which Stenhouse Williams advocated the production of clean milk from healthy cows and will also remember the apathy and misunderstanding he had to combat.

The First World War inevitably slowed down the work of the Institute, but plans were laid for future development and after the War an appeal committee was formed under the chairmanship of the Earl of Iveagh. Funds were collected which, together with Development Fund grants and very generous help from Lord Iveagh, financed the purchase of the Shinfield Manor Estate. The old Manor House was suitable for conversion into laboratories, and the farm buildings and 350 acres of farmland provided facilities for field trials.

The government of the Institute was now delegated by Deed of Trust to a Board the members of which represented the College, the Ministry of Agriculture, the Ministry of Health, the Royal Agricultural Society of England, the National Farmers' Union, the British Dairy Farmers' Association and the staff of the Institute.

Thus, 1920 saw not only a new form of government for the Institute and new premises but also a change of name to the National Institute for Research in Dairying. By 1923 the Manor House had been converted into laboratories and the staff, numbering ten scientists, seven laboratory assistants, a librarian and a small secretarial staff, occupied their new home.

These were exciting years with so much worthwhile research waiting to be done against a background of financial stringency—a history common to most research organizations in the years between the Wars. Nevertheless, the Institute grew and embarked on a wider programme of research, but it was to suffer a sad blow in 1932 by the death of its first director, a man much beloved by his colleagues who, with them, had pioneered the application of science to the dairy industry.

Prof. H. D. Kay succeeded Dr. Stenhouse Williams and remained director of the Institute until he retired in 1958. It was under his guidance that the Institute grew to its present size and acquired new departments and laboratories which provided the scientific facilities essential for the very much expanded programme of research. Dr. A. T. R. Mattick, who for many years had been head of the Bacteriology Department and deputy director, succeeded Prof. Kay and was acting director until 1959 when I came to Shinfield as director[*]. The total staff of the Institute now numbered about 370 and included a scientific and experimental staff of 114. This staff was distributed over the departments of dairy husbandry, feeding and metabolism, physiology, radiobiochemistry, bacteriology, chemical microbiology, chemistry, physics, engineering and nutrition. There were also an experimental dairy, a statistics section and a unit concerned with liaison work with the dairy industry. The departments acted as hosts for about fifteen visiting workers from overseas. The Institute now farmed some 700 acres and even with this acreage had difficulty in providing sufficient dairy cattle for experimentation.

At the end of June, in celebration of the Jubilee, the Institute held two open days which were attended by some five thousand visitors. The staff of the ten departments staged more than eighty exhibits to illustrate the research on which they were engaged. Results of investigations relating to reproduction and lactation were shown and included those of workers in the Physiology Department who have made significant contributions to knowledge concerning the hormonal control of growth of the mammary gland and the formation and removal of milk. Exhibits from other departments covered work on the metabolism of synthetic œstrogens in ruminants and the counting and sizing of spermatozoa electronically.

Three departments staged exhibits on the formation of milk. That from the Chemistry Department dealt with the different routes by which the individual fatty acids are metabolized in the ruminant and how the end-products of their metabolism affect the rate of synthesis of milk constituents. The other two exhibits, one from the Radiobiochemistry Department and one from the Physiology Department, dealt respectively with studies in which radioisotopes were being used to determine the chemical form in which fat is transported to the udder and with research concerning some key enzymes involved in the control of mammary gland and liver metabolism.

The Departments of Dairy Husbandry, Nutrition, Chemistry, and Feeding and Metabolism staged ten exhibits which dealt with the results of experimental work on the feeding of dairy cattle. These ranged over calf-feeding trials, rumen development, development of the secretion of digestive enzymes in relation to utilization of nutrients by young calves and studies concerning the absorption of magnesium and calcium as affected by age. In recent years dairy farmers and others have been concerned by the variations occurring in the solids-not-fat fraction of cow's milk, and for several years the staff of the Dairy Husbandry Department have examined the effect of inherent and environmental factors and prepartum feeding on the solids-not-fat and fat contents of the milk from

---

Fig. 1. The Manor House and Library at the National Institute for Research in Dairying, Shinfield, Reading

Friesian heifers. The results of these trials were demonstrated and had considerable interest for farmer visitors. Other exhibits dealt with requirements for energy and protein of growing heifers and factors affecting appetite.

For many years the staff of the Chemistry Department has been studying factors which affect the composition of cow's milk. More recently, the use of cows provided with rumen fistulæ has enabled quite rapid advances to be made in knowledge concerning the role of ruminal fatty acids in relation to milk composition, and these observations, together with the results of earlier experiments concerning diet and composition, were used to demonstrate how these findings may in time have a practical application in the formulation of feed mixtures. The same Department staged an exhibit based on work concerning genetic variations in milk proteins in the cow and related species and changes in protein distribution induced by stage of lactation.

Great interest was displayed in the prototype of an infra-red milk analyser designed for the automatic analysis of milk. This apparatus, developed by the Physics Department, is capable of determining fat, protein, lactose and solids-not-fat in a small milk sample in less than 1 min.

The Institute has made full use of its experimental dairy husbandry unit in developing and testing milking and management techniques, and visitors were able to see demonstrations relating to pipeline milking in parlour and cowshed, circulation cleaning, machine stripping, slatted floors and hygiene control of mastitis.

Staff in the Bacteriology Department staged exhibits to illustrate methods of evaluating disinfectants and bacteriological techniques used in mastitis investigations. Other exhibits dealt with the influence of different species of bacteria on cheese flavour and an attempt to relate flavour assessment by a tasting panel to the results obtained by an examination involving gas chromatography. Further demonstrations dealt with work relating to brown discoloration in Stilton cheese and the isolation of nisin and its characterization and practical application.

The staff of the Physics Department, in addition to demonstrating the infra-red milk analyser, showed apparatus which had been developed in the department for measuring the spreadability of butter and the results of work on the determination of the activity and purity of commercial rennets. A modified torsiometer for use in a cheese vat in measuring the 'firming up' of curd was also demonstrated.

The staff of the Nutrition Department, in addition to its interest in animal feeding and production, has been concerned with the assessment of the nutritive value of milk and other foods. Microbiological assay techniques have been developed for measuring vitamins and protein quality and these were demonstrated to visitors. In addition, the results were shown from comparisons which are being made of the nutritive value as between milk fat and various vegetable oils using rabbits and chicks as the experimental animals. A very extensive survey has been carried out in the Nutrition Department of the variations in vitamin A, carotene and tocopherol in milk fat throughout the year and scientific visitors were particularly interested in a newly adapted laboratory which has been air-conditioned for work involving the use of dangerous solvents.

Although the Institute is concerned mainly with the production and utilization of milk and milk products, a considerable amount of work has been done on pig nutrition, and the present work in the experimental piggeries was demonstrated and a display made of some practical applications of recent research findings in pig nutrition.

Recently, staff in the Nutrition and Bacteriology Departments have been using techniques involving the production of germ-free chicks. After preliminary work, a special unit has been built to house the 'germ-free' work, and it is hoped that these new facilities will enable staff to tackle further work on the role of micro-organisms in the nutrition of animals.

The staff of the Engineering Department design and manufacture many of the specialized instruments and pieces of equipment used in other departments, and specimens were on view. They also co-operate in many research projects, for example, in investigations of the spoilage of heat-treated milk and in problems associated with ultra-high-temperature sterilization of milk and the aseptic filling of this product into bottles.

Many departments in the Institute use the facilities of the Experimental Dairy. The staff of the Dairy, in collaboration with the Engineering Department, have developed an apparatus for enabling the continuous cheddaring of curd in the manufacture of Cheddar cheese. This apparatus was on view. Another process concerned with the continuous preparation of cheese curd has been developed by the staff of the Chemical Microbiology Department, and a film could be seen by visitors illustrating the work which has so far been done in connexion with the process.

The Institute possesses an excellent library which houses probably the largest collection of dairy literature in the world. It was erected as a memorial to Stenhouse Williams.

The demonstrations to visitors on these open days illustrate the distance which has been travelled since the early days when the staff of the Institute could be counted on the fingers of one hand. At this milestone in the history of the Institute it is only right to pay tribute to those who had the courage and vision to direct and carry out the research for which the Institute is held in such high regard the world over.

CÆSIUM-134 IN MAN

By KURT LIDÉN

Radiation Physics Department, University of Lund, Sweden

AND

INGVAR Ö. ANDERSSON

AB Atomenergi, Stockholm, Sweden

After the discovery of the high cæsium-137 body burden of Swedish Lapps in the beginning of 1961[1], measurements of larger groups of Lapps and other people on a similar diet have been performed both in Sweden and Finland. In August 1961, twelve Swedish Lapps were measured in the whole-body counter of AB Atomenergi, Stockholm[2]. With a small semi-portable whole-body counter, built in the Department of Radiation Physics, University of Lund, 160 persons were examined at Jokkmokk (66·6° N., 19·9° E.) in Sweden in September[3] and 190 persons at Inari (68·9° N., 27·0° E.) in Finland in October 1961[4]. In all these cases the whole-body γ-ray spectra contain the same peak or bump at 800 keV. as discussed in ref. 1. In Fig. 1 the γ-ray spectrum of subject L. B. measured at AB Atomenergi on August 16, 1961, with an NaI(Tl) crystal 4 in. in diameter and 4 in. thick clearly demonstrates a well-resolved peak at that energy. The net sum spectrum of 52 Finnish Lapps, each measured for 10 min. at Inari during October 20–24, 1961, is shown in Fig. 2. Also in this case the 800-keV. peak is present; the crystal size was 5 in. in diameter and 4 in. thick.

As the 800-keV. peak is not found in the γ-ray spectra of Swedes from the Stockholm and Lund areas at 59·3° N., 18·0° E. and 55·7° N., 13·2° E. respectively, it could be assumed that there was a relation between this peak and the increased cæsium 137 level in people on a reindeer meat diet in northern Sweden. Measurements at the Department of Radiation Physics during March–May 1961 of 3 Lapps by means of a 5 in. by 4 in. crystal showed that the mean ratio of the number of pulses in the full (extrapolated) 800-keV. photopeak and the full cæsium-137 photo peak was (1·65 ± 0·2) : 100. In reindeer meat, measured on March 11, 1961, the ratio was (1·42 ± 0·07) : 100. A study of 12 Lapps at AB Atomenergi in August 1961 gave a mean ratio of (1·2 ± 0·1) : 100 and no significant deviation between different human subjects. In Fig. 3 we have given the net γ-ray spectrum of reindeer meat extract obtained at AB Atomenergi on October 20, 1961; the potassium-40 contribution is subtracted. In this case the ratio is (1·10 ± 0·05) : 100. Thus in both series of measurements the 800-keV. peak to cæsium-137 ratio has the same value in meat and man within the statistical limits.

At AB Atomenergi an attempt was then made to determine the half-life of the 800 keV. peak[5]. 3 kgm. of reindeer meat was treated with concentrated nitric acid + 5 per cent sulphuric acid for about 15 hr., during the first 2 hr. at slightly increased temperature (50° C.). The fat floating on the surface was removed by filtering. The solution was then boiled until a black viscous liquid remained. It was treated with 30 per cent hydrogen peroxide at about 50° C. giving a colourless liquid. Water was added so that a sample of 1 litre of solution was obtained. A solid deposition remained at the bottom of the container. The sample was measured in an accurately defined geometry with a 4 in. by 4 in. NaI(Tl) scintillation spectrometer. The measurement was repeated after 130 days. The half-life was calculated both from the number of pulses in the 800-keV. peak and from the ratio of the number of pulses in the 800-keV. peak and the cæsium-137 peak. In the second case a correction has been made for the decay of cæsium-137. The average value of the half-life obtained from the experimental results is 2·4 ± 0·5 years.

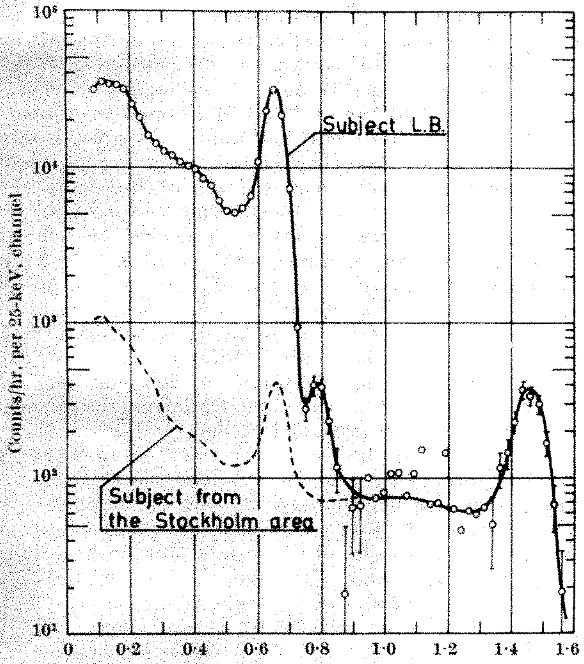

Fig. 1. Whole-body γ-ray spectrum of subject L. B. Cæsium-137 burden 0·60 μc.

When the 800-keV. component was found at the Department of Radiation Physics in March 1961, cæsium-134 was the first tentative interpretation of its origin but this hypothesis was rejected[1], since there was no known yield of cæsium-134 in nuclear weapons fission. However, results obtained from further investigations of the 800-keV. component, in the food-chain lichens–reindeer–man, strongly supported the first theory. A more direct approach in order to prove the theory was then made at the Department of Radiation Physics. The level scheme of cæsium-134, recently revised[6], shows that the most intense γ-ray lines at 605 and 797 keV. are emitted in cascade (Fig. 4). An attempt was then made to study the γ-ray spectrum of reindeer meat by a γ–γ coincidence technique. A 75-gm. sample of vacuum-dried meat, corresponding to 240 gm. fresh weight, in a cylindrical container 9 cm. in diameter by 1·5 cm. in height was placed between two crystals of NaI(Tl) 3 in. in diameter and 2 in. thick. One was connected to an integral discriminator (channel I) and the other to a 200-channel transistorized pulse amplitude analyser (channel II). Pulses in channel I corresponding to 530 keV. or more opened the gate of channel II. This coincidence system had a resolving time of 1 μsec. Two successful long-term runs were made, one at 45 hr. and one at 20 hr. The 45-hr. coincidence spectrum, corrected for background and potassium-40 contribution is plotted in Fig. 5. It shows two distinct peaks at 600 keV. and 800 keV. The increased counting-rate at lower energies is caused mainly by various Compton events. The random coincidence-rate is negligible even at the position of the cæsium-137 peak. A test with a cæsium-134 sample of the same size and density as the meat sample resulted in a coincidence spectrum of the same shape as for the meat.

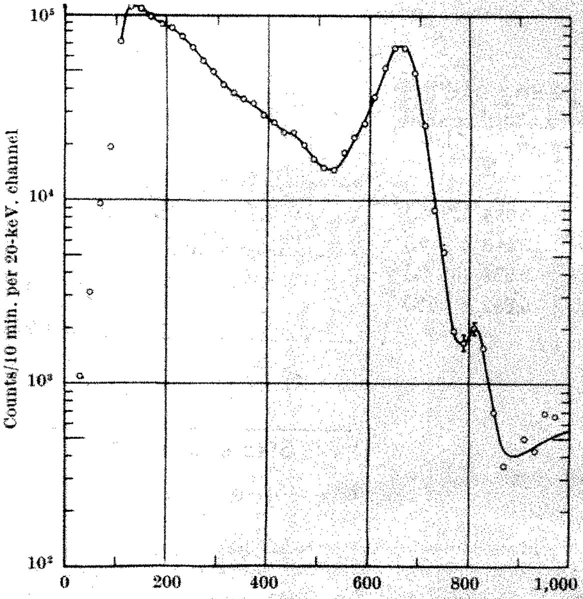

Fig. 2. Net sum spectrum of 52 Finnish Lapps. Average cæsium-137 burden 0·20 μc.

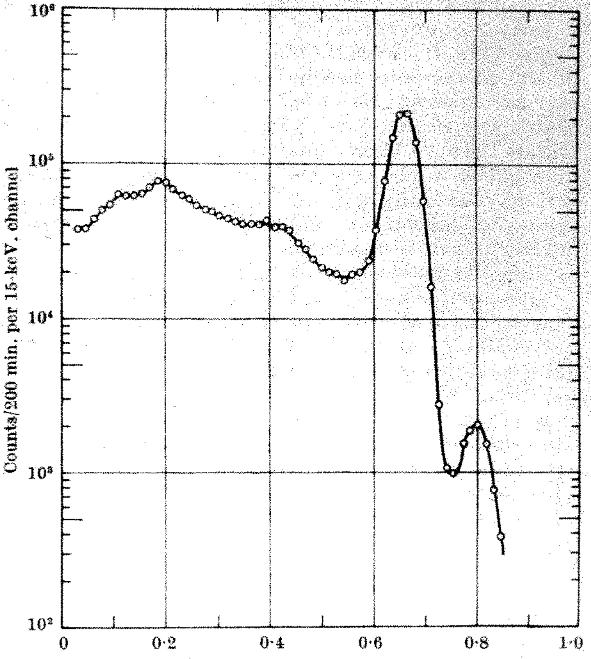

Fig. 3. γ-Ray spectrum of reindeer meat extract. Potassium-40 contribution is subtracted

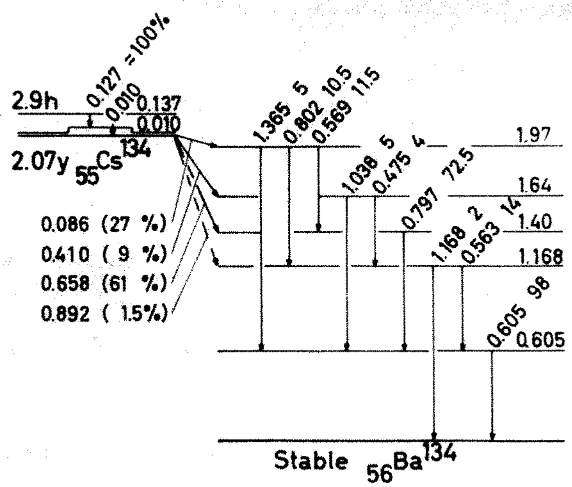

Fig. 4. Level scheme of cæsium-134

Thus these investigations have given us a knowledge of: (1) the energy of the 800-keV. peak; (2) its half-life of 2·4 ± 0·5 years, compared with 2·07 ± 0·02 years for cæsium-134 (ref. 7); (3) the presence of a 600-keV. γ-ray peak in coincidence with the 800-keV. peak. After correction for crystal efficiency the intensity ratio for these two peaks was found to be 10 : 6, in accordance with the level scheme for cæsium-134 from which the ratio 100 : 67 for the two groups 563 + 569 + 605 and 797 + 802 keV. is obtained (Fig. 4); (4) a metabolic behaviour of the 800-keV. component in reindeer meat and man very similar to that of cæsium-137.

That the origin of the 800-keV. peak in man's γ-ray spectrum is a cæsium-134 contamination of human tissue thus seems to be proved.

The origin of cæsium-134 in the biosphere is not known. There seem to be no figures in the literature concerning a direct cæsium-134 yield in fission. Indirect formation in the 134 mass chain by successive β-decay is prevented by the existence of stable xenon-134. Baerg *et al.*[8] found the independent yield of the metastable cæsium-134, half-life 2·9 hr., in thermal neutron fission of uranium-235 to be less than 1·4 × 10^{-5} per cent. From the measurements of March 1961 we have found the cæsium-134 activity in reindeer to be 1·6 per cent of the cæsium-137 activity assuming a total intensity of 0·83 photon per disintegration for the 800-keV. lines and correcting for crystal efficiency. This corresponds to a cæsium-134 yield of about 0·01 per cent.

An observation of cæsium-134 in soil samples taken close to the ground zero after an atomic balloon shot in Nevada is reported[9]. However, only a very slight indication of cæsium-137 was found, which is rather puzzling. Neutron-induction processes are suggested as a tentative interpretation in this case.

Cæsium-134 is produced in reactors by neutron activation of the stable fission product cæsium-133. There is no direct yield of cæsium-133, but it is created by the decay of other fission products. As this build-up of cæsium-133 is slow, it is not possible to interpret the biospheric cæsium-134 as a result of such an activation process in weapons tests. As cæsium-134 is produced in reactors, reactor release or reactor accidents might be the origin of this isotope in the biosphere. The isotopic composition of the fission product elements has been calculated for different irradiation times and three thermal neutron fluxes 10^{12}, 10^{13} and 10^{14} n./cm.²/sec. (ref. 10). If uranium-235 were irradiated at a neutron flux of 10^{13} for 6 months or at 10^{14} for 1 month the cæsium-134/cæsium-137 activity ratio would be about 1 : 3.

The Windscale accident in October 1957 was in fact detected in Sweden[11] and Norway[12]. A relatively heavy cæsium-137 fall-out was found at Bergen, Norway (60·4° N., 5·3° E.), during the period September–October 1957, which could be due to the Windscale accident. From that observation it can be estimated that about 10 per cent of the cumulative cæsium-137 fall-out up to August 1961 could be from that accident. If we assume that the cæsium-134/cæsium-137 activity ratio in the cæsium release from Windscale was 1 : 3, that ratio in the cumulative cæsium fall-out in August 1961 should be 0·8 : 100, a value which is the same, within a factor of two, as the ratio reported here. However, it should be emphasized that this is only a rough estimate. If the cæsium-134/cæsium-137 activity ratio in the Windscale reactor had been 0·05 as mentioned by Wheatley[13] our hypothesis will not hold. We would only wish to show that the release of activities from reactors has to be considered when discussing the possible origin of the biospheric cæsium-134. It remains to investigate other processes in nuclear weapons tests, for example, cæsium-134 fast neutron fission yield, multiple neutron capture, activation of non-fissionable material, etc.

Investigations of the ratio cæsium-134/cæsium-137 in biospheric samples from different parts of the world collected before September 1, 1961, are now in progress at the Department of Radiation Physics in order to check the proposed theory.

The radiation dose to man from cæsium-134 is small. From the newly proposed level scheme (Fig. 4) it can be calculated, using the proper geometric factor[14], that a uniform concentration of 1 μc. cæsium-134/gm. of tissue in a 70-kgm. standard man gives an average radiation dose of 1·43 rads/hr. (from β-rays 0·33 and from γ-rays 1·10 rads/hr.). For cæsium-137 the corresponding value is 0·91 rad/hr. (0·51 and 0·40). Thus, in this case the dose contribution from cæsium-134 is 1·6 times larger than from cæsium-137 per unit activity. In the case of Lapps with a total body burden of 0·5 μc. cæsium-137, which is not unusual, the radiation dose from cæsium-

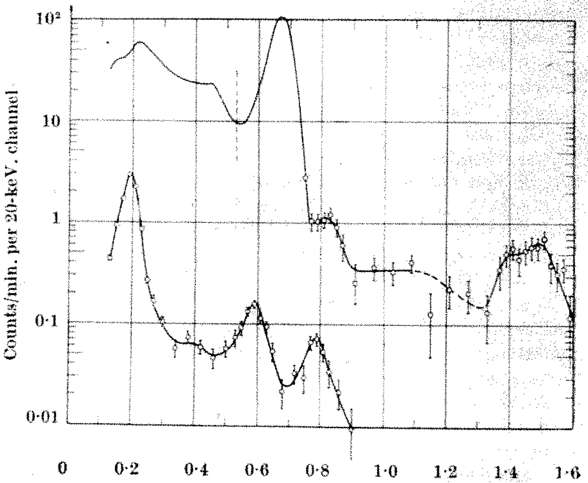

Fig. 5. γ–γ Coincidence net spectrum of a reindeer meat sample (lower curve, 45-hr. run) and a single crystal spectrum of the same sample in the same geometry (upper curve, 100-min. run)

137 is 57 mrad/year. An average cæsium-134 content of 1·5 per cent of the cæsium-137 level then contributes 1·3 mrad/year or approximately 2 per cent of the total radiocæsium irradiation. It should be added that the ICRP method[15] used in dose calculations for internal γ-ray radiation results in a 50 per cent higher dose than we have found for a standard man of 70 kgm., due to their approximation of the body as a sphere with 30-cm. radius.

AN EVALUATION OF CONTROLLED-TEMPERATURE ENVIRONMENTS FOR PLANT-GROWTH INVESTIGATIONS

By Dr. A. JOFFE*

Division of Crops and Pastures, Department of Agricultural Technical Services,
Pretoria, South Africa

A DOZEN years have elapsed since the first large-scale controlled environment facility for plant growth was erected at the California Institute of Technology, Pasadena. Interest in the use of this type of facility (a so-called 'phytotron') has increased rapidly in many countries, and there are at present more than a dozen phytotrons in the world, while the number of additional facilities of one type or another must now number several hundred.

At approximately the same time as the Pasadena phytotron was erected, the late Prof. M. G. Mes was responsible for the construction of a smaller and somewhat different installation at the University of Pretoria, South Africa. After twelve years of use, certain fundamental principles of design and operation have become apparent, and in view of the ever-increasing demand for controlled-environment facilities, which are necessarily expensive, it appears timely to evaluate the validity of some of the assumptions which seem to have been tacitly accepted.

The present article will be mainly limited to the fundamental aspect of temperature control. The attainment of reliable temperature control in the dark is relatively simple, the main problem undoubtedly occurring under conditions of high light intensity, especially in glasshouses, but also in growth rooms where radiation effects have to be considered. It is presumed that the usual object of a glasshouse is to grow plants under conditions of high light intensity and as near natural light quality as possible. Thus, the use of shading or other devices that impede the entry of light is not considered.

Some of the engineering problems of temperature regulation in a glasshouse have been discussed by Went[1], who has also pointed out that although it would be desirable to control accurately the temperature of the whole plant, it is impossible to produce an even temperature throughout a land plant exposed to light. He states further that "in general, leaf temperatures are rather close to air temperature, because on the one hand radiation and transpiration hold each other more or less in check, and because on the other hand the leaves are so thin that through conduction and convection they exchange heat easily with the surrounding air".

The heat-transfer principles involved are fundamental to the whole concept of temperature-controlled facilities, and the view expressed here does not appear to be in harmony with the numerous investigations on leaf temperatures and transpiration which have been published since the appearance of Curtis's[2] analysis of the problem 25 years ago. Leaf temperatures between 5° and 10° C, or more, above ambient temperature have been consistently reported for thin-leaved mesophytes in sunlight in widely differing latitudes and under various conditions. Far higher values have been recorded in the case of succulent plants and thick plant organs. If temperature differences of the same order exist between plant and air in a phytotron, they can scarcely be regarded as insignificant.

So far as can be ascertained, no work has been published to date on the temperatures of plants or other objects in a so-called, constant-temperature glasshouse. Measurements obtained in the Pretoria glasshouses over a number of years, using 40-gauge thermocouples, have shown that the temperature of leaves of various thin-leaved mesophytes supplied with adequate water was consistently above the ambient temperature during high-radiation periods. Values of +3° to +10° C have been obtained for more than ten species when the leaves were horizontally exposed to insolation values of approximately 1·0 cal cm^{-2} min^{-1}, a wind speed of 80–120 f.p.m., wind direction obliquely from above, and relative humidities of 30–75 per cent at a dry-bulb temperature of 22° C. Though this radiation value is high, it may undoubtedly be encountered in glasshouses in many countries of the world. The wind speed of approximately 100 f.p.m. appears, on the other hand, to be somewhat higher than that prevailing in most research glasshouses.

Temperature measurements of sand and other objects are presented in Fig. 1 and Table 1, and from these it is evident that the actual temperature of objects in a glasshouse may bear little resemblance to the air temperature. Root medium temperatures

---

* Present address: Margaretha Mes Institute for Plant Physiology and Biochemistry, University of Pretoria.

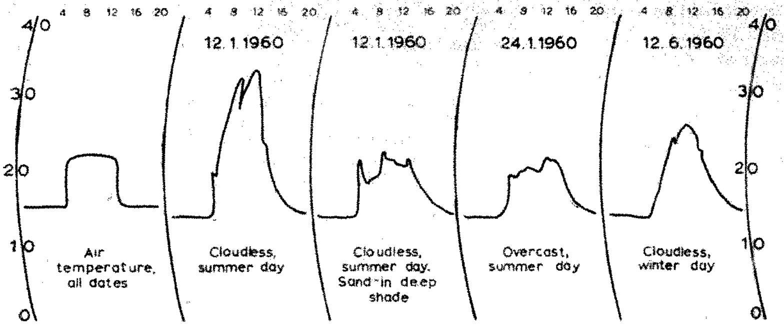

Fig. 1. Extracts from typical distance thermograph records of river sand in asbestos flats, 39 × 45 × 12·5 cm deep, in an air-temperature-controlled glasshouse. Thermograph elements 4 cm below sand surface. Water at 24° C applied at 8.00, 12.00 and 16.00 h in summer, and at 18° C applied at 12.00 and 16.00 h in winter. Wind speed, 100 f.p.m., direction obliquely from above

may be more than 11° C higher on a clear summer day than on an overcast day in a constant-air-temperature glasshouse (Fig. 1).

Certain controlled temperature experiments have been conducted in the glasshouses at this Institute in summer and have been repeated as exactly as possible in the winter: significantly different results were obtained. An analysis of the results suggested that one of the main variables was plant, and especially root, temperature rather than light intensity or quality.

Raschke[3] has recently stated "that it is surprising that the botanist neglects the significance of the infra-red radiation exchange; radiation laws have been known for 80 years and such contributions as Curtis's provide the proper emphasis". Curtis[2] had expressed the view as early as 1936 that, for interpretation of certain physiological experiments, air temperature readings alone may be highly misleading. Yet with the advent of highly efficient control equipment for air-conditioning purposes, the assumption is usually made that, once air temperature is controlled, everything else will look after itself. (The reliable control of air temperature is, in itself, not always simple under conditions of high insolation especially when low ventilation-rates are utilized. The air temperature in, for example, a return air-duct, where it is sometimes monitored, will not necessarily be the same as in the vicinity of the plants. Ideally, the reference air temperature should be that of the plant-growing space, this in fact being possible in practice.)

This approach is evidenced by the principles of design and construction sometimes used in phytotrons. In discussing these principles, it is necessary to stress that, for a given radiation-level and ambient temperature, the most important external and readily controllable factor affecting the temperature of plants and other objects is the rate of ventilation. The effect of wind speed on various objects exposed to high radiation in a glasshouse is presented in Fig. 2. The exponential nature of the curves has a great bearing on the thermodynamic and aerodynamic principles involved in the successful air-conditioning of a phytotron. It should be noted that, unlike the evaporimeter, the temperature of leaves and certain other objects approaches asymptotically the air temperature with increasing wind speed.

Table 1. SURFACE TEMPERATURES OF OBJECTS IN AN AIR-TEMPERATURE-CONTROLLED GLASSHOUSE MAINTAINED AT 22° C

Object	Surface temperature (°C)	Increase above ambient (°C)
River sand, wet	29	+ 7
River sand, dry	46	+24
Red loam soil, wet	31	+ 9
Red loam soil, dry	48	+26
Cotton wool, dull white	36	+14
Cotton wool, red	47	+25
Water-culture, in 1 l. white container	27	+ 5
Black seedcoat of *Phaseolus* sp. in moist, closed glass Petri dish	53	+31

Readings obtained with 40-gauge thermocouples under following approximate conditions: radiation, 1·0 cal cm^{-2} min^{-1}; wind speed, 100 f.p.m., direction obliquely from above; relative humidity, 50 per cent.

The usual method of air injection in most phytotrons appears to be from a perforated or slotted floor. It has been claimed that this system produces a uniform temperature régime in the glasshouse or growth room. With a carefully designed distribution system this is possible provided the chamber is not utilized for plant-growth purposes. As soon as plant containers standing on trolleys are introduced into the chamber the entire air-flow distribution pattern undergoes a radical change: high resistances to air flow are introduced and the ventilating air is channelled into passages between the trolleys. Thus, the wind speed is far higher in the non-growing spaces than in the space above the plants. This results in a zone of relatively stagnant air where the effect of radiation will be at a maximum. Of equal importance is the effect of this system on the microclimate immediately above an individual plant container; when air is passed in an upward direction between containers, a non-uniform flow pattern exists in the zone above the pots. This is due to the back-flow of air above the soil surface, resulting in the formation of vortices and 'dead-spot' areas.

The degree of inefficiency of the slotted floor ventilation system will depend on the size and spacing of the containers. However, even with liberal spacing, the position is aggravated by the presence of overhanging and intertwining foliage which is sometimes unavoidable. The cost of controlled environment space on a unit area basis is normally too high to permit the luxury of isolated plant containers, even if the 'dead zones' above the containers could be eliminated.

If the effect of incoming radiation on plant and soil temperatures is recognized and the nature of the effect of increasing wind speed on the heat balance is considered, one must come to the conclusion that the attainment of greatest uniformity of air, plant and soil temperatures is only possible if a relatively high wind speed and maximum uniformity of air movement in the correct direction are present.

The most satisfactory method of accomplishing this in a glasshouse or growth room appears to be the use of one or other lateral overhead distribution system. If the air distribution equipment is located at the maximum height on one of the long walls of a correctly oriented glasshouse, that is, the long axis east–west, then shadow effects are largely or entirely eliminated. Provided the width of the glasshouse does not exceed certain limits, air distribution is satisfactory with injection from one side only[4].

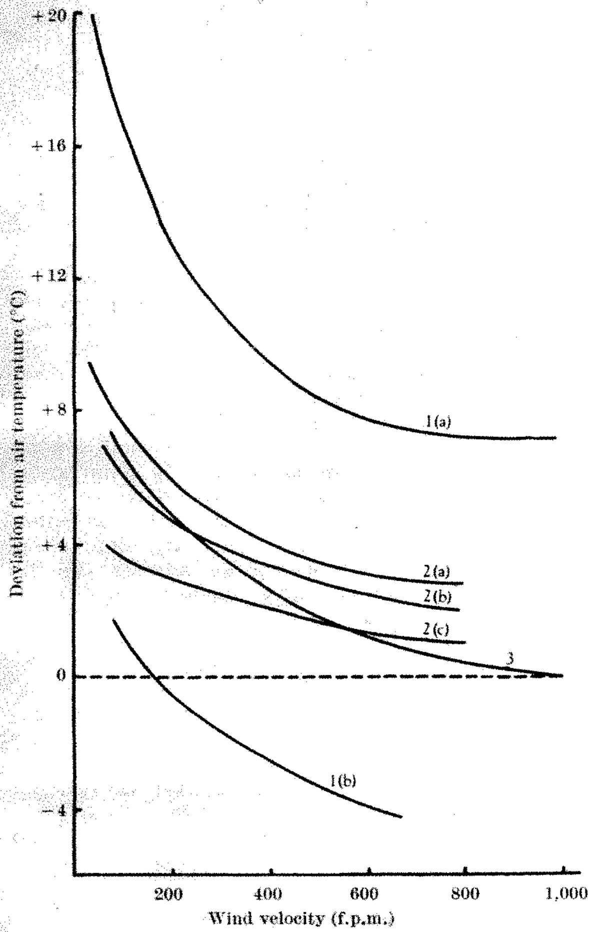

Fig. 2. Effect of wind speed on the temperature of objects in a glasshouse maintained at an air temperature of 22° C. Radiation, 1·1 cal cm^{-2} min^{-1}; humidity, approximately 50 per cent; wind direction, obliquely from above

1, green cloth, 3·5 cm square, (*a*) dry, (*b*) wet; 2, leaf temperatures, (*a*) *Fuchsia* sp., (*b*) *Fragaria* sp., (*c*) *Lotus corniculatus*, L.; 3, surface of wet river sand

Two methods of air distribution incorporating these principles have been used: (*a*) from one or more separate fans, usually in conjunction with evaporator coils and heating elements; or (*b*) by means of a continuous distribution duct with discharge slots, the duct being so designed as to produce a constant static pressure along its length. The advantage of the latter system lies in the fact that differences in wind speed and consequently temperature are at a minimum in the controlled area. These systems operate on the principle that relatively high-velocity jets of air are discharged in the unoccupied space above the plants in one direction, while air movement in the occupied space occurs in the opposite direction. Mixing of the incoming conditioning air occurs in the unoccupied space of the chamber and, in general, wind movement in the plant growing zone is predominantly lateral, but movement in the vertical direction is also present because of air entrainment. By using correctly chosen air velocities and slot areas to produce the desired entrainment ratios and terminal velocities, it has been shown that a high degree of uniformity with regard to wind speed and air temperature can be attained[4], thereby promoting uniform plant and soil temperatures. It must be stressed, however, that perfect conditions can really only be expected in a wind tunnel, and even then the presence of tall plants on the upstream side of shorter plants may create imperfect conditions.

It has been suggested that, because radiation effects are in any event present in Nature, it may as well be left that way in the phytotron. However, the main object of a phytotron does not appear to be to reproduce Nature but rather to obtain as complete control of the environment as possible, one of the objects being the reproduction of experimental conditions in time and in space both within and between chambers and even between institutes.

In the case of temperature control under high or variable radiation-levels, especially in a glasshouse, this is not entirely possible with any system. By making use of existing knowledge of heat-transfer principles it is, however, possible to reduce aberrations. From the nature of the curves presented in Fig. 2 it is evident that by simply using a uniform ventilation-rate of approximately 250–300 f.p.m. over plant and soil surfaces, the effect of radiation is considerably reduced (but not eliminated); wind speeds above this value become proportionately less effective for cooling purposes. Under conditions of adequate water supply, this wind speed is neither harmful to plant growth[5] nor difficult to attain in practice and ensures a satisfactory supply of carbon dioxide to plants for a given number of air changes per unit time.

In view of the nature of the heat transfer processes, one may well ask what purpose is served by installing expensive and highly accurate equipment under variable or high-radiation conditions. In the case of a glasshouse, the presence of a shadow from the structure or a passing cloud can considerably change the temperature of objects in a very short while. Even under constant insolation, temperature differences exist due to, for example, self-shading of leaves, partial shading of the soil and variations in long-wave radiation from other objects. Under conditions of net radiation loss, plant and soil temperatures will often be below ambient temperature (Fig. 1). These facts also serve to indicate the desirability of properly controlled root temperature facilities, independently from aerial temperature control and protected from radiation effects[6]. It is also evident that morphological and anatomical properties of a plant may influence not only the volume of the total heat exchange but also the predominance of one or other heat transfer process[3].

These facts show how pointless it really is to place a literal meaning on the usual statements that a phytotron experiment was conducted at a particular temperature plus or minus a negligible deviation.

Fortunately, radiation effects on objects in the phytotron are virtually independent of the air temperature, while the other components of the energy exchange are only relatively slightly affected by ambient temperature. Valuable comparative results of the influence of temperature can be, and have already been, obtained from phytotron experiments, and this should serve as an incentive to study in detail the many aspects of the control of the environment in modern installations.

EXPERIMENTAL FOLDING IN ROCKS

By Dr. M. S. PATERSON and Dr. L. E. WEISS*

Department of Geophysics, Australian National University, Canberra

ONE of the most common features of bedded or foliated rocks seen in the field is the folding of surfaces which are presumed to have been initially plane. This folding may have arisen in a number of ways, depending on the circumstances, and it has been the subject of many theoretical and experimental investigations. Theoretical studies have been concerned mainly with the buckling of layers embedded in material of different properties (for example, Biot[1]). Most experimental investigations have aimed at simulating folding, using model materials such as wax, putty or 'Plasticine' (for example, Ramberg[2]). However, folding has not hitherto been produced experimentally in rocks except in a slight degree (ref. 3, Fig. 44).

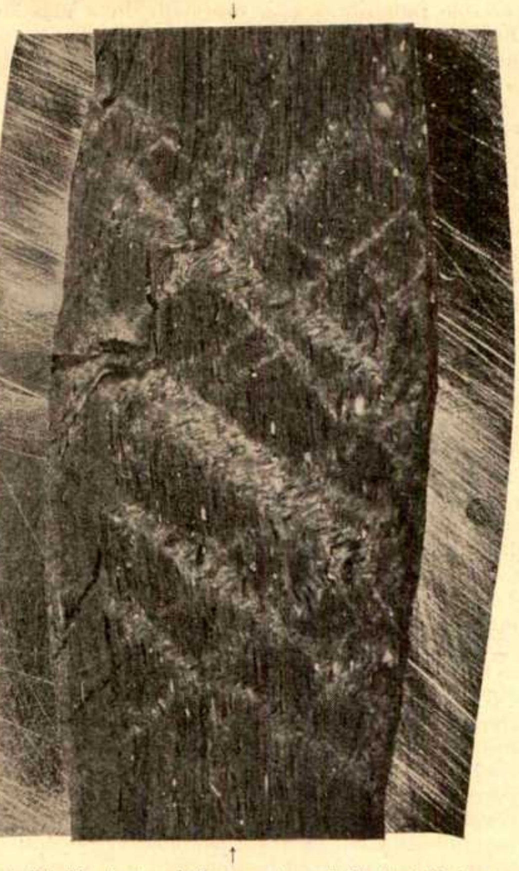

Fig. 1. Phyllite shortened 13 per cent parallel to the foliation in thick brass jacket, showing development of kinking. (Polished section, × c. 6.) (In all figures, arrows indicate direction of differential load)

Field study suggests that folding often involves flexural slip on the folded surfaces, a process analogous to bend gliding or kinking in crystals. Such behaviour is believed to be characteristic of the deformation of rocks such as slates, phyllites and mica schists which are already strongly foliated. We give here a preliminary account of experiments on a fine-grained phyllite and a mica schist in which prominent kinking and folding by flexural slip have been achieved, leading to microstructures that are strikingly similar geometrically to many structures observed in the field in such rocks.

The phyllite consists mainly of chlorite and sericite, with some fine quartzose layers and, in some specimens, an appreciable number of relatively large clastic quartz grains. Cylindrical specimens 7 mm. in diameter and 10 or 20 mm. long have been cut at angles of 0, 10°, 25° and 45° to the foliation. In the main series of experiments, the specimens have been sealed into thick brass or copper jackets of 10 mm. outside diameter.

The deformation experiments have been carried out at room temperature and at a confining pressure of 5,000 kgm. cm.$^{-2}$. The specimens were compressed between parallel platens, without a spherical seat, at a rate of shortening of the order of 1 mm. per min. The total strains corresponded to relative changes in length ranging from 5 to 80 per cent.

The following are the main observations on the phyllite specimens which were jacketed in thick brass or copper:

(1) Except in the most highly strained specimens, there is no substantial dimensional change in the cross-sectional direction parallel to the foliation. Therefore, since the behaviour remains elastic in this direction while large permanent changes in length occur in other directions, the rock is markedly anisotropic mechanically. This anisotropy is a reflexion of the dominant role of gliding or slip on the foliation as the mechanism of deformation.

(2) At small strains, narrow bands of kink folding appear at approximately 50° to the direction of shortening. In the specimens compressed parallel to the foliation, the kink bands are in symmetrically oriented conjugate sets (Fig. 1), and where the foliation crosses successively two conjugate kink bands

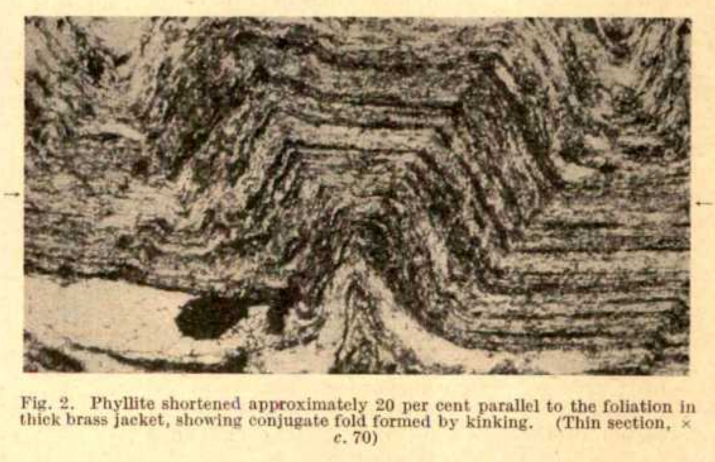

Fig. 2. Phyllite shortened approximately 20 per cent parallel to the foliation in thick brass jacket, showing conjugate fold formed by kinking. (Thin section, × c. 70)

---

* On leave from the University of California, Berkeley.

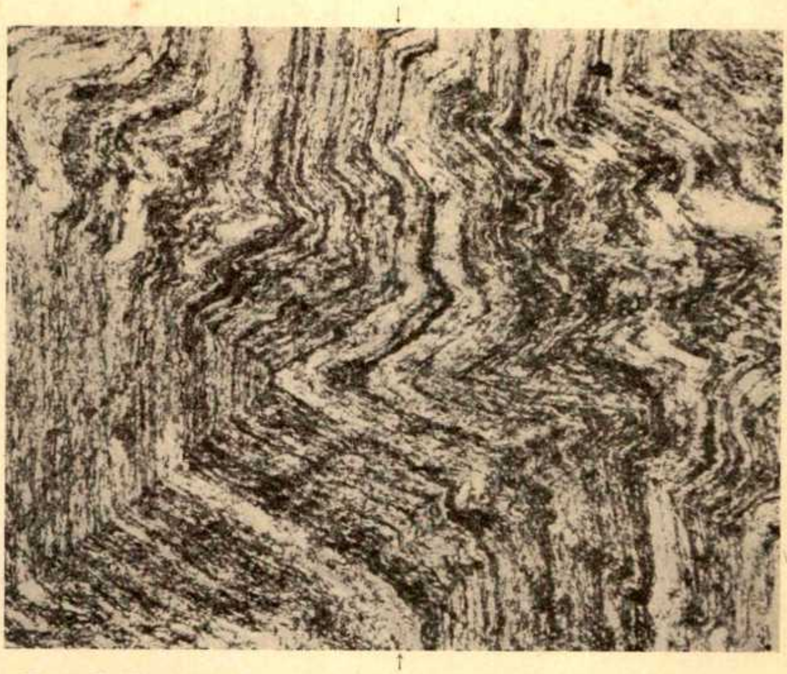

Fig. 3. Phyllite shortened approximately 20 per cent parallel to the foliation in thick brass jacket, showing folds formed at intersection of kinks. (Thin section, × c. 65)

Fig. 2) it shows the form of a conjugate fold[4]. In the other specimens, the kink bands are asymmetrically developed and in specimens compressed at 25° and 45° to the foliation only one set of kink bands generally appears. For all orientations, the kink bands grow in number and width as the strain increases, almost filling the whole specimen when 30–40 per cent shortening is reached.

(3) In the domains where kink bands intersect, folds appear in the foliation which are distinctly different in style and orientation from the folds forming the kink bands (Fig. 3). Whereas the kink folds are asymmetrical and open, with axial planes inclined to the specimen axis, these folds are commonly symmetrical in form and tightly appressed, with axial planes perpendicular to the specimen axis; they closely resemble the similar folds so widespread in strongly deformed rocks. The more highly strained specimens in which the coalescence of intersecting kink bands is nearly complete tend to contain only folds of this kind (Fig. 4). With further strain, these folds become more tightly appressed (Fig. 5). In contrast to the predominant similar folding in the phyllite, individual quartz layers which have deformed cataclastically show concentric folding (Fig. 5).

(4) In specimens compressed at 25° and 45° to the foliation in which only one set of kink bands develops, such a second generation of folds does not appear at moderate strains (Fig. 6). Instead, further deformation is by uniform gliding on the foliation accompanied by external rotation of the glide plane, similar to that observed in single crystals deformed by gliding (ref. 5, Plate 3).

In other experiments, specimens of mica schist were compressed parallel to the foliation in thick brass jackets. The mica schist consisted mainly of muscovite and biotite with some quartz and was of much coarser grain size than the phyllite. After deformation, it showed extensive kinking and small-scale folding, generally similar to that observed in the phyllite.

In some further experiments on specimens of phyllite jacketed only in rubber, the structural development was different:

(1) In specimens compressed parallel to the foliation, the deformation was mainly concentrated in two conjugate kink bands, one near each end of the specimen so that they intersected to only a small extent.

(2) In specimens compressed at 45° to the foliation, there was no kinking. The deformation took place inhomogeneously by gliding in the foliation within

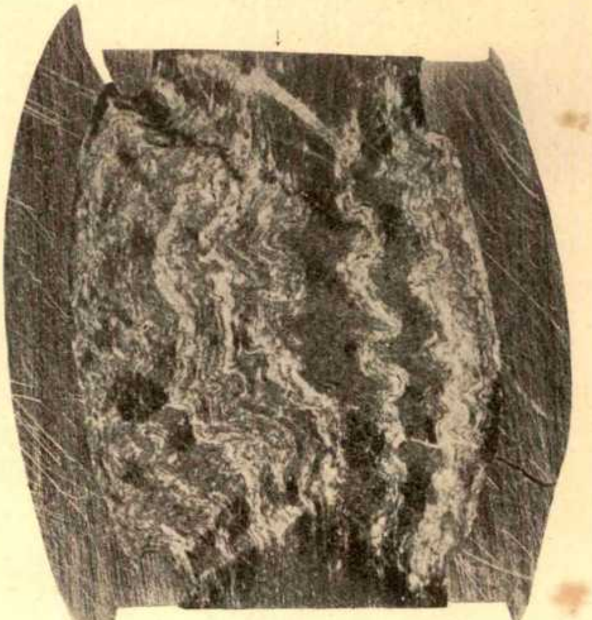

Fig. 4. Phyllite shortened 30 per cent parallel to the foliation in thick brass jacket, showing development of folding. (Polished section, × c. 5)

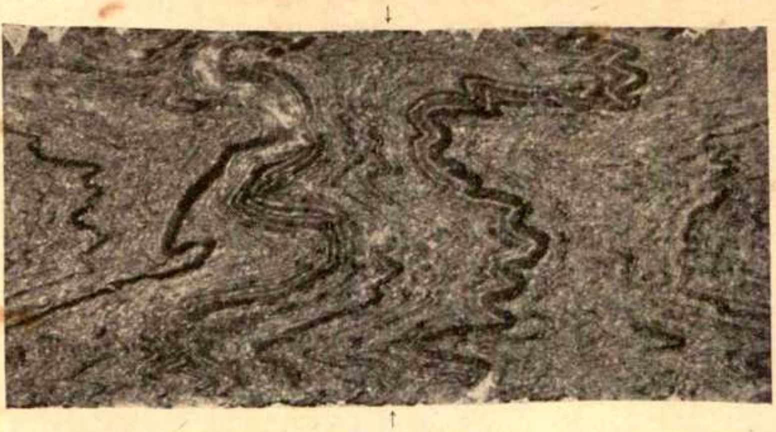

Fig. 5. Phyllite shortened 70 per cent parallel to the foliation in thick brass jacket, showing advanced stage of folding (central portion of specimen only). (Polished section, × c. 15)

central parts of the specimen, during which one end of the specimen slid laterally on the platen so that no change in the orientation of the foliation occurred (Fig. 7). This behaviour is the simplest expression of the basic mechanism of deformation in the rock in these experiments.

Clearly, therefore, the constraint offered by the thick brass or copper jackets strongly influences the structures produced by preventing the development of major inhomogeneity or arbitrary change of shape such as is observed in specimens jacketed only in rubber; that is, the role of the thick brass or copper jacket is to prescribe the gross strain in the specimen, which can only be realized by small-scale kinking and folding because the strong planar anisotropy restricts gliding to the foliation plane. In this prescription of the gross strain, the experiments go some way to simulate natural situations in which a given part of a body of rock undergoing deformation is not free to change its shape arbitrarily, but must conform with the deformation of neighbouring parts of the same body. It is presumably mainly for this reason that the structural features produced are similar to many occurring naturally in such rocks. Otherwise, it must be emphasized that the present combination of physical conditions (short duration, room temperature, confining pressure equivalent to that at about 15 km. depth) may not be representative of the natural conditions under which such types of folding are produced. However, it is believed that the observations in these experiments are of considerable value in aiding the geometrical understanding of the development of similar folding by flexural slip in foliated rocks, including such aspects as the orientation of kink bands and of axial planes of later folds relative to the mean strain ellipsoid and the close connexion between the generation of the similar folds and the intersection of kink bands.

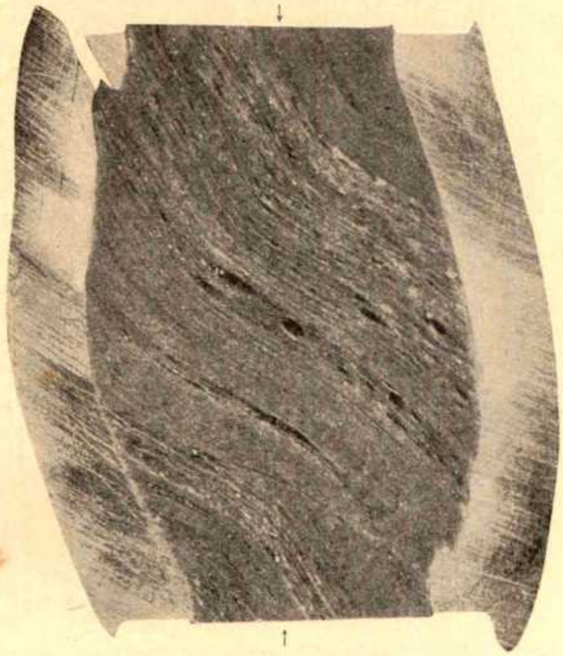

Fig. 6. Phyllite shortened 28 per cent in direction at 25° to the foliation in thick brass jacket, showing absence of small-scale folding in early stages of deformation. (Polished section, × c. 5)

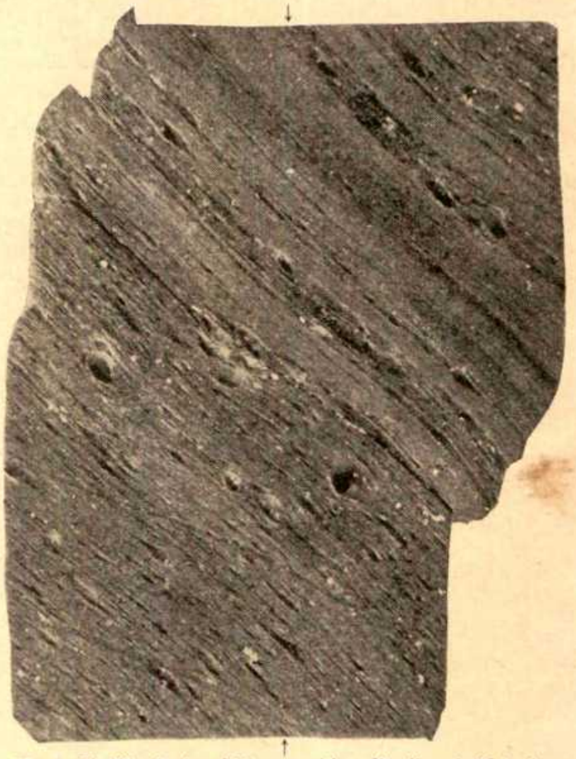

Fig. 7. Phyllite shortened 19 per cent in a direction at 45° to the foliation in rubber jacket only, showing simple gliding on the foliation. (Polished section, × c. 8)

A fuller description and more detailed analysis of the results will be published elsewhere. One of us (L. E. W.) thanks the Guggenheim Foundation for a fellowship which enabled him to visit the Australian National University and take part in this work.

OBITUARIES

Dr R S Bassler

RAY SMITH BASSLER, who died on October 3, 1961, was born at Philadelphia on July 22, 1878 He was the last link with some of the earlier American geologists —he numbered James Hall among those he had known His childhood was spent in Cincinnati, where he came to know not only the abundant, local, well-preserved fossils but also, through them, such local (and later famous) geologists as J M Nickles, Charles Schuchert and E O Ulrich Their influence on his career was lasting

While Bassler was still at high school, Ulrich took him as a part-time assistant in his business of selling fossils (including thin sections of Palæozoic Polyzoa), and the boy learnt much After Schuchert had gone to be curator of invertebrate fossils at the United States National Museum in Washington, Bassler followed him there as assistant curator His scientific life was thus settled, and, after his retirement in 1948 as head curator, he was made associate in palæontology

Bassler's world-wide reputation rests mainly on his work on the Polyzoa He published several papers on the Palæozoic forms, notably on those of the Baltic Provinces (1911) and of Timor (1929) But it is by his voluminous joint papers with Ferdinand Canu on tertiary and recent Polyzoa that he is best known Their extensive research work, carried on for nearly twenty years from 1913, has profoundly influenced all later investigations into the systematics and structure of the post-Mesozoic Polyzoa

Bassler's duties at the U S National Museum necessarily entailed studies of other groups Thus he wrote (sometimes in collaboration with others, and especially with Ulrich) on echinoderms, ostracods, conodonts and sponges The first two claimed much of his attention, and he published a classification of the Edrioasteroidea in 1935 The last years of his life were largely devoted to a study of the Cystoidea, on which he had already published in 1943

Bassler had a flair for bibliographical compilation, and he published indexes of Polyzoa, ostracods, pelmatozoan echinoderms and Palæozoic corals Perhaps his best-known work of this kind is his *Bibliographic Index of American Ordovician and Silurian Fossils* (two volumes, 1915)

From his early days Bassler was keenly interested in stratigraphy, particularly that of the Lower Palæozoic, and in 1932 his *Stratigraphy of the Central Basin of Tennessee* appeared, based largely on his own field-mapping He also wrote the large *Cambrian and Ordovician* volume of the Maryland Geological Survey (1919)

Despite the great amount of time that Bassler spent on his official duties, he still found the energy to lecture at the George Washington University, where he was assistant professor during 1904–43 His friendly nature warmed to the difficulties and ambitions of youth, and he was regarded with affection by his students The University conferred on him an honorary D Sc in 1932

Besides filling various posts in American societies, Bassler was a correspondent of the Academy of Natural Sciences of Philadelphia Abroad, he was elected a foreign member of the Geological Society of London, an honorary member of the Natural History Society of Tartu, and a foreign correspondent of the Geologiska Foreningen, Stockholm

Energetic and vital as his work showed him to be, Bassler nevertheless could readily relax He welcomed visitors to the Museum and to his home, and delighted in showing them the sights of Washington, he was well read and cultured, with a tolerant outlook, and he never forgot his numerous friends.

H DIGHTON THOMAS

Dr A T R Mattick, C B E

DR A. T R MATTICK died at his home in Reading on July 2, 1962, nearly three years after his retirement from the National Institute for Research in Dairying.

Mattick was a student at University College, Reading, and obtained the Degree of B Sc as an external student of the University of London He served in the forces in the First World War and, after being demobilized, he returned to Reading to join the staff of the Research Institute in Dairying as an assistant for bacteriological research The Research Institute was, of course, the forerunner of the National Institute for Research in Dairying where Mattick spent his working life He became head of the Bacteriology Department and during 1946–58 was deputy director of the Institute On the retirement of Prof H D Kay from the directorship of the Institute, Mattick acted as director until Prof R G Baskett became director in 1959 [see also p 1038 of this issue] Mattick was a founder member and a president of the Society of Dairy Technology and served as president of the Society of Applied Bacteriology For twenty-seven years he was joint editor of the *Journal of Dairy Research* and acted as associate editor of the *Journal of General Microbiology*

Mattick entered the field of dairy bacteriology at a time when huge losses were being sustained by the dairy industry because of the lack of elementary hygiene In these early years the production of clean milk was a crusade, and Mattick as a worker, talker and fighter must have enjoyed every moment of it He and his colleagues fought and won the battle of dirty churns and they brought to a successful conclusion the campaign for bacteriological standards relating to designated milk His writings on the production and distribution of clean milk have become classics in their field

While Mattick had a clear understanding of the practical application of bacteriology to farm problems and the problems associated with milk distribution, his contributions to the advancement of the science of bacteriology were considerable and he played a leading part in the recognition and isolation of the antibiotic, nisin Shortly before his death the use of nisin was permitted as a food preservative

Mattick will be remembered as an outstanding character and a lively and interesting speaker whether on the platform or in private conversation On occasion he could appear brusque and he spoke and acted without fear or favour in the interest of what was just and right Those who knew him well recognized his essential humanity and he himself frequently asserted that people were more important than things His understanding of individuals was swift and accurate and his ready kindness could on occasion be tempered with more or less astringency according to the recipient

As he was a man of special and unique quality, so will be the affection with which his colleagues remember him

N J BERRIDGE

Prof W Rothmaler

PROF WERNER ROTHMALER, the well-known plant taxonomist, died at Greifswald, East Germany, in April 1962

Rothmaler was born in 1908 in Thuringia, he went to school at Weimar and then to the University of Jena At the age of twenty-five he emigrated to Spain, where he worked at the Botanical Institute in Barcelona, he later moved to Lisbon and worked there at the Estação Agronomica Nacional It was during this period that he made important contributions to the taxonomy and ecology of the flora of the Iberian Peninsula, and he retained an interest in this area all his life

In 1941 he was recalled to Germany and served as a soldier in Greece, where he was attached to a mapping unit In 1943, because of illness, he returned to Germany and after a short stay in Berlin found a home in Vienna with Prof Wettstein In 1944 he became director of the Botanical Department at Gatersleben and in 1945 went to Halle, where he became professor in 1950 In 1953 he made a final move to Greifswald, where he was appointed director of the new Institute for Agrobiology, and he remained there until his death, though he continued to travel widely

Rothmaler published many papers, and was known as an authority on the genera *Alchemilla* and *Antirrhinum* He recently produced an excellent short Flora of Germany, the final, critical volume of this was nearly complete at the time of his death and will probably appear soon He proposed as early as 1944 the preparation of a Flora of Europe, a project which had to be abandoned because of war-time circumstances, but he co-operated whole-heartedly in the new Flora Europæa and had already given much valuable assistance In this, as in other botanical research, both in his own country and internationally, his early death leaves a place difficult to fill

Rothmaler's interests both inside and outside science were unusually wide, he was an active exponent of the philosophy and history of science, and had expert knowledge of many branches of art and archæology British botanists, many of whom had got to know him during the past ten years, will miss him greatly To work with him in the field was an unforgettable experience, wise, witty and critical, he could always produce the right comment and the illuminating observation

He leaves a widow and four children

D H VALENTINE

NEWS and VIEWS

Scientific Attaché in Moscow

T Garrett

MR TERENCE GARRETT has been appointed scientific attaché to the British Embassy in Moscow and will take up his post this month He succeeds Dr D A Senior, who was the first to hold this post (see *Nature*, 183, 1018, 1959), and who is moving to the Department of Scientific and Industrial Research's Forest Products Research Laboratory on completion of his term of appointment As scientific attaché Mr Garrett will advise the British Ambassador (Sir Frank Roberts) on scientific matters, promote scientific contacts and report on Soviet scientific and technical development in the civil field Mr Garrett, who is 32, is at present senior lecturer in the Department of Mathematics and Physics at the Royal Military College of Science, Shrivenham Mr Garrett attended Alleyn's School, Dulwich, and then won an open scholarship to Gonville and Caius College, Cambridge, where he read mathematics He went on to take a diploma in mathematical statistics with chemical engineering as a special field of application Before going to Shrivenham he was, for a year, lecturer and head of the Mathematics Section at Ewell Technical College Mr Garrett, who speaks Russian and German fluently, has for some years been interested in the problems of translating technical literature and in the statistical analysis of languages He has written about education in the U S S R and the Russian Orthodox Church He has been to the U S S R several times, recently as interpreter at the British Trade Fair in Moscow

Biology in the University of East Anglia

Prof J Dainty

DR JACK DAINTY has been appointed professor of biology in the new University of East Anglia, Norwich Dr Dainty was a pupil at Mexborough Grammar School and obtained an Exhibition in mathematics at Queens' College, Cambridge, where he obtained firsts in the Mathematics Tripos Part I and Natural Sciences (Physics) Tripos Part II For six years he did research and teaching in nuclear physics at the Cavendish Laboratory, where he was in charge of the cyclotron After the Second World War he worked for a short time at Chalk River He came to the Natural Philosophy Department at Edinburgh in 1949 and, after some years spent building up the High Tension Laboratory, decided that biology was perhaps the most interesting branch of physics Appointed reader in biophysics at Edinburgh in 1955, he has since built up a research and postgraduate teaching department that is unique in Britain Dr Dainty's main interest is in the permeability and electrical properties of cell membranes, working particularly on the giant internodal cells of the Characeae He has developed and applied the as yet incomplete methods of non-equilibrium thermodynamics to permeability studies, and has stressed the serious errors that can arise from the use of simpler less rigorous methods Dr Dainty will no doubt attempt at Norwich to encourage a more rigorous and quantitative approach to biological teaching and research Dr Dainty has also wide interests in natural history He will be fully aware of the proper importance of field work and ecology, particularly in a county such as Norfolk

New Chemical Enzymology Unit for Shell Research

DR J W CORNFORTH, for some years a member of the National Institute of Medical Research, and Dr G J Popják, at present director of the Medical Research Council's Experimental Radiopathology Research Unit, will be jointly in charge of Shell Research's new Chemical Enzymology Unit They will be assisted by Dr Rita Cornforth, wife of Dr John Cornforth, and a group of experienced biochemists and technical assistants The Unit will have a new laboratory at Sittingbourne, in Kent (due for completion in April 1963) Its work will embrace both basic research and research on topics of shorter-range interest—mainly in the sphere of 'biological chemistry', on which Shell Research largely relies in the development of pesticides and herbicides

Babcock and Wilcox Nuclear Development Center

Dr W M Breazeale

Dr William M Breazeale, a nuclear scientist who holds the first reactor operator's licence issued by the U S Atomic Energy Commission, has been appointed director of the Babcock and Wilcox Co Nuclear Development Center Comprising a 3 5 million dollar test reactor and nuclear fuel laboratory, now under construction, and an existing critical experiment laboratory, the Center is being established near Lynchburg, Va Dr Breazeale will be responsible for providing laboratory and experimental support to the Atomic Energy Division, which has overall responsibility for the Company's nuclear power business Joining Babcock and Wilcox Co in 1956 as assistant manager in the Atomic Energy Division's Nuclear Engineering Department, Dr Breazeale became assistant manager of the Project Management Department in 1959, and in 1960 was made senior technical adviser for the Division Dr Breazeale received his first degree from Rutgers and later took his Ph D degree in physics at the University of Virginia at Charlottesville

International Academy of Astronautics

Corresponding Members

The following have been elected corresponding members of the International Academy of Astronautics of the International Astronautical Federation

Basic Sciences Section Prof Edoardo Amaldi, Istituto Física Università, Rome, Prof K O Kiepenheuer, Fraunhofer Institut, Freiburg i/B , Prof S K Mitra, national research professor, Institute of Radio Physics and Electronics, Calcutta, Dr Svein Rosseland, Institute of Theoretical Astrophysics, Oslo University, Blindern, Dr Harry Wexler (now deceased), U S Weather Bureau, Washington, D C , Dr John R Winckler, professor of physics, Institute of Technology, University of Minnesota, Minneapolis

Engineering Sciences Section Dr Sydney Goldstein, Harvard University, Cambridge, Mass , Dr William R Hawthorne, Engineering Laboratory, Cambridge, England, Dr Hideo Itokawa, Institute of Industrial Science, University of Tokyo, Dr W F Klemperer, Douglas Aircraft Co , Santa Monica, Cal , Dr Hans W Liepmann, California Institute of Technology, Pasadena Cal , Mr George P Sutton, manager, Long Range Planning, Rocketdyne, Canoga Park, Dr Herbert York, chancellor, University of California at San Diego, Cal , Mr M J Zucrow, Jet Propulsion Center, Purdue University, Lafayette, Indiana

Life Sciences Section Dr Pierre Biget, Centre d'Enseignement et de Recherches de Médecine Aéronautique, Paris, Dr E O Errebo-Knudsen, Institute of Aviation Medicine, Copenhagen, Dr O H Gauer, Freien Universitat, Berlin, Dr C J Lambertsen, University of Pennsylvania, Philadelphia, Mr Alfred M Mayo, manager, Advanced Systems Department, Astronautics Division, Chance Vought Corp , Dallas, Texas, Dr Hermann Rahn, Department of Physiology, University of Buffalo, N Y , Dr Cornelius A Tobias, Donner Laboratory, University of California, Berkeley, Dr F M Violette, Centre d'Enseignement et de Recherches de Médecine Aéronautique, Paris, Lt -Col Stanley C White, Life Science Division, National Aeronautics and Space Administration, Langley Air Force Base

The Academy now has a total membership of 140, from 22 countries The second meeting of the officers and trustees of the Academy will be held during the Thirteenth Congress of the International Astronautical Federation at Varna, Bulgaria, on September 25

Employment of Graduates

The sixteenth annual report of the University of Durham Appointments Board covering the academic year 1960–61 records that the demand for mathematicians continued to mount faster than supply, and that the similar position with physicists also worsened (Pp 12 Durham The University Appointments Board, 1962) On the other hand, the demand for chemists eased and the supply of chemical engineers began to catch up with demand, but while there were very few vacancies for geologists, especially in industry, the shortages of good mechanical and electrical engineers remained chronic Demand for arts graduates from all employers remained good, and more women found jobs in the chemical and allied industries, mainly in consumer research and information work The nationalized industries remained unpopular, but as a whole the public service gained more recruits, especially in central government departments, local government had little attraction Competition for the most outstanding engineers, scientists and arts graduates intensified, whereas the least-able and least-effective had more difficulty in locating suitable employment Grave concern is expressed over the numbers entering the teaching profession in arts and science alike there was a distinct drop in the numbers of both men and women going on to train as teachers, and the numbers of women science graduates and of men arts graduates taking up teaching posts untrained also decreased Comment is made on the ineffective character and handling of recruitment literature, the doubling of the number of men entering the private sector of employment, and the quadrupling of the number of men entering public service

The Australian Society of Limnology

At a meeting held at Monash University on May 26 a constitution was drawn up for an Australian Society of Limnology The objectives of the Society will be "To establish effective liaison between all persons interested in any aspect of fresh and brackish water research in Australia, and to promote the study of and encourage these interests in State and Commonwealth Research Institutes and Departments, and educational Institutions" The means of attaining these objectives will be "(*a*) The establishment and maintenance of a register of all persons working in appropriate fields in Australia and adjoining countries, giving details of their current interests and relevant publications, (*b*) The holding of an annual congress which will coincide with the annual general meeting, (*c*) The production of a *Newsletter* by an editor to be appointed by the executive" At the meeting the following officers were elected *President*, Dr A Nicholls, *Vice-President*, Mr J Lake, *Secretary-Treasurer*, Dr W Williams Further information and details of membership can be obtained from Dr. W Williams, Department of Zoology and Comparative Physiology, Monash University, Box 92 P O , Clayton, Victoria

Freedom in Science in the Nineteenth Century

Dr J R Baker's essay, "The Controversy on Freedom in Science in the Nineteenth Century", describing the debate between E Haeckel and R Virchow beginning at the Congress of German Naturalists and Physicians at Munich in September 1877, which originally appeared in the volume of essays, *The Logic of Personal Knowledge*, presented to Prof M Polanyi on the occasion of his seventieth birthday, has now been issued by the Society for Freedom in Science as *Occasional Pamphlet* No 22 (Pp 13 Oxford Assistant Secretary, Society for Freedom in Science, Department of Zoology, University Museum, 1962 1*s*) Dr Baker shows how radically this controversy differs from that which developed in the 1930's and 1940's, and notes how it led to the exclusion of biology from the curricula of all senior classes in schools—a result which neither Haeckel nor Virchow could have foreseen and which both must have deplored No one then had any intention of restricting the fredom of research workers to choose the subjects of their investigations, and, although it is not clear exactly what Virchow proposed, it is probable that he was concerned solely with the schools, where it is appropriate that instruction in science should be mainly factual

Idiopathic Clubbing of Fingers in the African

From time to time Africans are admitted to medical wards with a gross degree of finger and toe clubbing, it is difficult to determine its cause The clubbing is pronounced and cannot be missed, and, except for this, the patients enjoy good health Similar cases occurring in other members of the family are not mentioned On the other hand, clubbing is commonly met with in an African medical practice due to such diseases as chronic and sub-acute pulmonary disorders, notably bronchiectasis, lung abscess, bronchial carcinoma, empyema, silicotuberculosis and also, occasionally, in tuberculous disease of the lungs, when a bronchiectatic basis is a possible explanation Heart disease also accounts for a number of cases including congenital lesions, sub-acute infective endocarditis and aneurysm of the aorta Liver disease is often met with in the African, but Dr Michael Gelfand, physician to the Harare Central Hospital, Salisbury, is not satisfied that this is a factor in its causation Although steatorrhœa is given as a cause, this is rarely seen in the African The same causes of clubbing apply also to hypertrophic osteoarthropathy, in which an idiopathic variety has been described Dr Gelfand has not detected this and, in the *Central African Journal of Medicine* (8, No 6, June 1962) a case of clubbing is described for which no possible explanation can be found

Conservation of Marshes, Bogs and other Wetlands

Alarmed by the progressive loss of marshes, bogs and other wetlands through drainage and 'improvement' the Executive Board of the International Union for Conservation of Nature and Natural Resources proposed early in 1961 that the Union, in close co-operation with the International Council for Bird Preservation and the International Wildfowl Research Bureau, should develop a programme on conservation and management of temperate marshes, bogs and other wetlands to be called 'Project MAR' The final goals of the programme are to prepare a broad statement on the importance of marshes and wetlands to modern mankind and to give the widest publicity to this statement, to assemble all important data on means of conserving wetlands, to keep and improve them for wildlife through proper management, to restore them when debilitated and to make man-made aquatic habitats useful for wildlife, to make this information known and available to all those in a position to take action to advance the conservation of wetlands, to make an inventory and classification of all European and north-west African marshes, bogs and other wetlands of international importance and to offer technical assistance for the establishment of reserves in marshes, bogs and other wetlands classified as of international importance The initial 'Project MAR' is described in an issue of the *Bulletin* of the International Union for Conservation of Nature and Natural Resources (New Series, No 3, April–June 1962)

Myxomatosis Survey

D A Chapman, of Oundle School, has described investigations into myxomatosis (Oundle School Natural History Society, Annual Report 1961 Pp ii + 54 Oundle Oundle School Natural History Society, 1962) The survey was begun after several rabbits with the disease had been noticed on a small stretch of road between Warmington and Morborne Since then records have been made by many boys of the School and information collected from farmers and game-keepers within a five-mile radius of Oundle The aim of the survey was to find the effect of the disease on the numbers of rabbits within this area Chapman describes many observations on diseased rabbits "In the later stages I have seen rabbits crouching in the grass with their ears folded backwards over their backs and the fur ruffled by the wind They remain motionless for a long time like this, and I would not be surprised that if not interrupted they would stay like this until they die Before the eyes have completely sealed over the rabbits still eat, but after this they lose their appetite " "Before the eyes sealed the diseased rabbits seemed to prefer to keep together, but once they close they lose each other and would scatter I have never seen a diseased rabbit run into a burrow, and, where there is an infected warren, often the holes have not been kept clean, being semi-blocked by leaves and twigs Whether the diseased rabbits go into burrows or are not allowed by the still healthy ones I do not know In the advanced stages of the disease they sometimes take to wandering, and eventually die 11 to 18 days after infection " Nearly every farmer in the area affected north of Oundle pays a yearly membership to the Rabbit Clearance Society The rabbit clearance worker, whose territory covers the north-west of the area, is fully employed and estimates that there are no more than about 70 rabbits in his small district On February 8, ferrets were put into a set of warrens near Glapthorne Cow Pastures and only one rabbit was killed Before myxomatosis had been found, three ferrets were put into the warren and 47 rabbits were shot in a morning

Verbal Learning and Verbal Behaviour

ALTHOUGH new psychological journals proliferate almost as rapidly as the rats which feature so extensively in their contents, there is perhaps a need for a journal devoted to the special problems of human verbal behaviour *The Journal of Verbal Learning and Verbal Behaviour*, under the editorship of Dr Leo Postman and an all-American editorial board, should go far to meet this need and provide a focus for psychological work in this admittedly specialized field ((1, No 1 (July 1962) Pp 78' New York and London Academic Press, Inc, 1962 Subscription Volume 1 (6 issues), 1962, 15 dollars)) The first issue contains papers on one-trial learning (a matter of some significance for modern statistical learning theories), paired-associate learning, and some effects of grammatical category on rote learning and word association The appearance of this journal would no doubt have given warm pleasure to Hermann Ebbinghaus, from whose heroic labours in mastering strings of nonsense syllables the modern interest in verbal learning may be said to have sprung

The Harkness Fellowships of the Commonwealth Fund—New York

THIRTY Harkness Fellowships of the Commonwealth Fund—New York are tenable during 1963 for education and travel in the continental United States The fellowships are offered to candidates from the United Kingdom, Australia, New Zealand and Western Europe, who are British subjects, and either are graduates or have experience in Government service, the professions, the arts, branches of business or industry or other comparable careers or vocations, and have the equivalent of a degree in qualifications conferred by professional bodies or an attested level of professional competence Forms of application, which must be returned before November 15, can be obtained from the Warden, Harkness House, 38 Upper Brook Street, London, W 1, from whom further information can be obtained

Nuclear Reactor Chemistry and Technology

THE third conference on "Nuclear Reactor Chemistry" and the sixth conference on "Analytical Chemistry in Nuclear Reactor Technology", sponsored by Oak Ridge National Laboratory, will be held in Gatlinburg, Tennessee, during October 9–11 Subjects under discussion will include preparation of fuel, moderator, coolant and nuclear poison materials and their properties in the presence and absence of nuclear radiation, particle behaviour in nuclear reactor accidents, chemical problems of organic moderated and organic cooled reactors, the chemistry of corrosion processes in nuclear reactors, use of isotopes in analytical chemistry, instrumentation, analysis of organic moderators, spectroscopy, analytical developments in radiochemistry and nucleonics Further information can be obtained from Oak Ridge National Laboratory, P O Box X, Oak Ridge, Tennessee

Announcements

THE second interscience conference on "Antimicrobial Agents and Chemotherapy" will be held in Chicago during October 31–November 2 Further information can be obtained from the American Society for Microbiology, 19875 Mack Avenue Detroit 36 Michigan

THE second world congress of undersea activities, organized by the British Sub-Aqua Club and the World Underwater Federation, will be held in Westminster during October 18–24 Further information can be obtained from Kendall McDonald, 4 Pytchley Crescent, Upper Norwood, London, S E 19

A MEETING of the British Biophysical Society will be held in University College, London, during December 17–18 The programme will include two symposia physical aspects of electron microscopy, structure of the nucleus Further information can be obtained from Prof D D Eley, Chemistry Department, University of Nottingham, University Park, Nottingham

AN autumn meeting on metallurgy, organized by the Société Française de Métallurgie, will be held in Paris during October 15–19 The themes of this meeting will be high temperature-resisting metals and alloys, and the use of the vacuum and rarified atmosphere in metallurgy Further information can be obtained from La Société Française de Métallurgie, 25 rue de Clichy, Paris 9

THE sixth plenary meeting of the World Power Conference will be held in Melbourne during October 20–27 The technical programme will include energy resources, the production and amelioration of primary sources of energy, transformation of primary to secondary energy and transportation of energy, utilization of primary and secondary energy, economic evaluation of alternative energy sources Further information can be obtained from the Australian National Committee, World Power Conference, 1 Collins Place, Melbourne, C 1, Victoria

"SPACE SPECTROSCOPY" is the title of a meeting of the Spectroscopy Group of the Institute of Physics and the Physical Society to be held at the headquarters of the Institute and Society on October 12 Speakers will include Dr R Tousey (U S Naval Research Laboratory), Dr J Lindsay (U S National Aeronautics and Space Administration), Dr K A Pounds (University of Leicester) and Dr D W O Heddle (University College, London) Further information can be obtained from the secretary, Dr L Bovey, Building 329, Atomic Energy Research Establishment, Harwell, Didcot, Berks

THE second international symposium on "Phosphorylated Glucides" will be held in Milan during October 12–14 The programme will include biology of phosphorylated glucides, phosphorylated glucides and metabolism of the myocardium, phosphorylated glucides in cardiosurgery and anæsthesiology, phosphorylated glucides and metabolism of the myometrium, phosphorylated glucides in physiopathology and therapy of liver, phosphorylated glucides in physiopathology and therapy of the nervous system, metabolism diseases and phosphorylated glucides Further information can be obtained from the Organizing Committee of the Second International Symposium on Phosphorylated Glucides, Via Modica 6, Milan

ERRATUM In the article entitled "The Future Natural Sciences Programme of Unesco" by Dr Hilliard Roderick which appeared on p 215 of the July 21 issue of *Nature*, the percentages 50, 40 and 10 should be inserted in place of 56, 10 and 10 respectively in the fourth paragraph on p 221 (section iii)

THE UNITED KINGDOM ATOMIC ENERGY AUTHORITY

THE eighth annual report of the United Kingdom Atomic Energy Authority*, covering the year ended March 31, 1962, contains 73 pages, compared with 70 in the previous report However, the material is arranged in 16 instead of 13 chapters, the new chapters being on magnox reactors and on plasma physics (incorporating fusion research), as well as one on supporting technical developments, that on controlled thermonuclear research has now been dropped A chapter, "Isotopes and Irradiation Programme", replaces that on "Commercial Operations" Even more noteworthy, for the first time, an estimate is included of the Authority's expenditure on research and development which, over the next five years, is put at about £50 million per annum For 1961–62, the current expenditure on this programme was £33 million with £16 million on capital expenditure, of this, £21 million was expended on the reactor programme, £4 million on general reactor technology, £5 million on general research, £2 million on plasma physics and fusion research, and £1 million on isotopes research Out of 2,740 graduate or professional - engineers or scientists employed on the whole programme at March 31, the corresponding deployment at the end of the year was 1,460, 300, 520, 170 and 90 The level of general research is designed to provide the minimum necessary effort on fundamental problems in such fields as nuclear physics, chemistry and metallurgy, together with the essential scientific basis for the Authority's development activities, while that in the field of reactor technology includes work on materials for reactors and for their fuel

The Authority's non-industrial staff increased slightly during the year, from 20,234 to 20,543, while the number of industrial employees fell from 20,606 to 20,017 From the review of the Authority's forward civil research and development programme, and the known trends in the weapons and production fields, it seems probable that the total manpower will remain roughly steady for the time being Recruitment of non-industrial staff was generally satisfactory during the year, but the Authority did not secure quite as many qualified scientists and engineers from the universities as were needed It is suggested that the wide range of interesting work which will continue to be available for scientific and engineering graduates of many disciplines is not yet fully appreciated Recruitment of non-industrial staff has recently been confined to younger people, especially those leaving school or completing a first or research degree at university, and this will be the future general policy, so that reliance for the future succession to managerial posts is in the main placed on staff who have made their careers with the Authority

The net expenditure in 1962–63 is estimated at £67,875,000 compared with £78,071,000 in 1961–62, which included some £6 million for the National Institute of Research in Nuclear Science, and includes some £4 881,000 for research, development and design contracts with industry, the universities, etc (compared with £4,531,000 in 1961–62) Commercial sales during the year realized more than £20 million, with an additional £500,000 for consulting services and royalties Sales of isotopes yielded a return on capital of more than 7 per cent The first two contracts with the Central Electricity Generating Board for fuel elements were signed in May 1961, and a contract to supply fuel for the Latina nuclear power station in Italy in December 1961

The production reactors and processing plants continued to perform satisfactorily, process efficiencies were improved during the year, and progress on the advanced gas-cooled reactor supported the expectation that electricity generated from such stations will be as cheap as, and later cheaper than, electricity generated from conventional stations in the United Kingdom In the reactor development programme much experimental work was concentrated on the oxidation of the graphite moderator by the irradiated carbon dioxide coolant A vigorous programme of research aimed at an economically attractive marine propulsion unit is being carried out in conjunction with the United Kingdom industry, and a working group on marine reactor research has been set up to advise and make recommendations on the programme of research required to advance nuclear propulsion for merchant ships A team to consider the design of a marine reactor has been formed within the Authority, and a team of engineers has been seconded from the British Shipbuilding Research Association to study the special features of the design operation and safety of a nuclear ship

During the year, 332 unclassified reports were issued and 390 papers by members of the Authority's staff were published in periodicals From the topics selected for mention in the chapter on general research and development, only a few can be taken as illustrative Research at Culcheth on radiation damage in stainless steels containing niobium has given interesting results, and the investigations are continuing to obtain a clear understanding of the phenomena and to determine methods of fabrication and heat treatment which will eliminate embrittlement A wide programme of general research into ceramic fuels stimulated by their high promise for power reactors includes investigation of the release of fission product gases in irradiated oxide ceramic fuels, the stability of various phases in the uranium–plutonium–oxygen system over a range of temperatures including those used in fuel fabrication and in reactor operation, and the investigation of carbides of uranium and plutonium Small-scale exploratory studies are being made of the possibilities of direct conversion of heat to electricity, while in nuclear physics improved detectors for charged particles have been developed at Harwell from silicon which can discriminate between particle energies closely similar in value and respond rapidly to a particle, producing an output signal within a hundred-millionth part of a second Further development of these semi-conductor detectors is directed particularly at establishing production methods and finding ways of making larger detectors

---

* United Kingdom Atomic Energy Authority Eighth Annual Report for the period 1st April, 1961–31st March, 1962 Pp ix+87+4 plates (London H M S O , 1962) 6s 6d net

Basic nuclear research is being carried out with the view of improving the imperfect understanding of the arrangement of the constituent particles within nuclei and of the forces that hold them together Work has continued at Harwell on the nature and properties of radioactive aerosols, with particular attention being directed to iodine A new laboratory designed specifically for remotely controlled experiments of plutonium critical assemblies came into use at Dounreay, and considerable progress was made at the Culham Laboratory site where the objective is the generation of power from fusion reactions In the extensive research in plasma physics, the key problem is the stability of the plasma and magnetic field system, and the emphasis of the experimental work is on those systems of magnetic confinement thought theoretically to be stable

THE GHANA SCIENCE ASSOCIATION

THE Ghana Science Association held its second annual congress during June 28–July 1, at the University of Ghana The highlight of the conference, the start of which coincided with the ending of the Accra assembly on "The World Without the Bomb", was the participation of a number of scientists from various other countries who were in Ghana for the Accra Assembly The visiting scientists had been informed of this meeting before their arrival in Ghana, and some of them read papers to the Association during the conference, including Prof J D Bernal (United Kingdom), Prof Ivan Supek (Yugoslavia), Prof Gerd Burkhardt (West Germany), Sir Robert Watson-Watt (U S A), Prof Alexjandro Lipschutz (Chile) and Dr H Marcovich (France)

The Ghana Science Association is a body in Ghana which is devoted solely to encouraging scientific and technological research and advancing both the understanding and teaching of science To this end, the Association provides a forum for scientists working in Ghana and guests from outside It also serves as a medium for informing the public of the part which science and technology are playing and can continue to play in the development of Ghana

The second annual congress was opened by the Minister Responsible for the National Research Council of Ghana, Mr Kofi Baako, who deputized for Osagyefo Dr Kwame Nkrumah, who is president of the Ghana Academy of Sciences—Prof J D Bernal having given a pre-conference open lecture on June 22 on "The Origin of Life" In his opening address, the Minister recognized that science was no magic wand with which to convert poor deserts to rich fertile lands, but that hard work was what was needed in all scientific endeavours The presidential address was given this year by Dr S R A Dodu In his speech, which set a high standard, Dr Dodu traced in outline the stages of development in the history of medicine He observed that contemporary primitive practices are often just echoing fragments of the past activities of pre-scientific man, and that by means of science we are able to dissipate superstitions and fears based on ignorance and to evaluate and assess the traditions and inherited customs by which we habitually order our lives and finally shape the very destiny of mankind

Later that evening, Dr H Marcovich, of the Pasteur Institute in Paris, gave an open lecture, the topic of which was, "Small Doses of Radiation, What are Their Biological Effects?" In his lecture, Dr Marcovich produced evidence to question the assumption in some quarters that small doses of radiation had no biological effects of any significance

There were two full sessional days, namely, June 29 and 30, and on each there were two morning sessions and one afternoon session, each session consisting of three papers The evenings were taken up by some open items

The first morning session on June 29 was under the chairmanship of Dr P M J Phillips, deputy chief medical officer It was devoted to subjects of medical importance such as "Drugs and the Organization of Mind", by Dr A C Mundy-Castle of the National Institute of Health and Medical Research, Accra, "Age and Tuberculosis Morbidity", by Dr E Laing of the Department of Botany, University of Ghana, and "Structure and Activity of the Steroid Hormones", by Prof J A K Quartey of the Department of Chemistry University of Ghana The first of these papers aroused great interest, and the speaker dealt with the varied characteristic disturbances evoked in humans by certain drugs and the investigations being carried out on the biochemical origin of madness He also showed cases where similar disturbances were induced without resort to chemicals In Dr Laing's paper an analysis of variance carried out on tuberculosis morbidity data in parts of Ghana showed a significant positive regression of morbidity with age Prof Quartey traced some of the chemical problems encountered in obtaining hormone substitutes in sufficient quantities for clinical hormone therapy, in particular that of determining the required structural features of the steroid molecule.

The second morning session concerned some aspects of agricultural research, under the chairmanship of K A Quagraine, chief scientific officer The first in this series was a paper by O Snow, adviser on agricultural matters to the Ministry of Agriculture on "The Economics of Agricultural Research" Recognizing that research is one item in the cost of production, Mr Snow considered, in an exploratory fashion, the problem in Ghana as to how much money can justifiably be spent on agricultural research, with the provisos that the research is well guided, gives results and is efficiently utilized The second speaker was P Ahn of the Faculty of Agriculture, University of Ghana, who read his paper on "Climate, Soils and Agriculture in the Forest Zone" (of Ghana) He showed in an elegant manner how the differences in rainfall in various parts of the forest zone are related to differences in the type of forest, both in floristic composition and in structure, and also to important differences in the soils The speaker emphasized that, as a result, both soils and natural vegetation can be correlated with agricultural belts The final paper in the series, on "Land Capability Classification of the Soils of Ghana", was read by Mr H B Obeng and Mr G K Smith, both of the Scientific Services Division of the Ministry of Agriculture The paper attempted to make a preliminary classification of the soils of Ghana under seven capability classes The classification, which is based on the American system, involves a critical evaluation of a number of important soil characteristics and the degree of limitation of each soil to mechanized farming and management It aimed at ensuring proper use of land and efficient crop and livestock production From the discussion that followed this excellent attempt, it became obvious that the scheme would have to be modified when more results became available concerning soils in Ghana

The afternoon session, under the chairmanship of Dr J Yanney-Wilson of the Department of Botany, University of Ghana, consisted of a mixed bag of topics The first speaker, H R B A Prempeh, acting regional agricultural officer for the Eastern Region, read a paper on "Improvement of Poultry in Ghana by Progeny Testing" He called for a programme by which the small number of imported birds which have been able to maintain their high breeding values could be 'progeny-tested' to form a foundation stock Dr J D Thomas, senior lecturer in zoology, University of Ghana, next gave his paper on "A Preliminary Account of the Life-cycle of *Mesocoelium monodi* (a trematode)" This parasite is widely distributed in West Africa and elsewhere in the tropical belt, and could be used as type specimen in tropical schools The last speaker was Dr O Davies, reader in archæology at the University of Ghana, and his topic was "The Stone Age in West Africa" The speaker, who is well known for his work in this field, gave a general account of the stone-age cultures in West Africa south of the Niger–Senegal, and showed a number of specimens that he had collected

There were two open items later that evening Prof Ivan Supek, professor of theoretical physics and philosophy at the University of Zagreb, spoke on "Science, Philosophy and Art", and after supper there was a symposium on "The Hopes and Dangers of Atomic Energy", under the chairmanship of Sir Robert Watson-Watt.

The second sessional day, June 30, commenced with the first morning session which was devoted to physics Under the chairmanship of Prof A Nunn May of the Department of Physics, University of Ghana, the session started with a paper by Prof Gerd Burkhardt of the Institute of Theoretical Physics, Hanover, West Germany He spoke on "Some Aspects of Plasma-Physics" Prof Burkhardt stated that the great interest now shown in research concerning the plasma-state of matter stems from the problem of controlling thermo-nuclear reaction The long-range forces between charged particles which make the kinetic behaviour of a plasma different from that of a neutral gas give rise to different modes of wave propagation, characteristic of a plasma, he then showed how these space charge waves could excite electromagnetic waves which are observed from the Sun and other cosmic bodies in the radio-frequency range The next paper was on "Atomic Reactor Research in Ghana", by Dr A H Ward of the Radio-Isotope Research Unit at Legon He gave a simple explanation of the construction and operation of reactors in general and, in particular, the *VVR–C* tank-type, and ended with an evaluation of the proposed 2,000-kW research reactor for Ghana in the light of its timing in the general development plans of Ghana, the capabilities of the reactor and its cost, including the problem of highly trained personnel The final speaker in the series was Father J R Koster of the Department of Physics, University of Ghana, who read a paper on "Some Recent Scientific Applications of the Doppler Shift" With illustrations of tape recordings, Father Koster showed how Doppler shift techniques are now being applied to some recent problems in ionospheric studies and satellite location

The second morning session, with Prof Hugh Nicol as chairman, had a zoological bias G C Rawson and J N N Adjetey, fisheries officers at Tema, read a paper on "The Development of Fishery Resources" in which they emphasized the need to tackle fisheries development from the aspects of biology, technology and economics E A Kwei, also a fisheries officer at Tema, read a paper on "The Spawning Migration of *Sardinella aurita* (Val)" He showed that the appearance of this very important fish near the shore coincided with its spawning, which thus has effect on the fishing season in Ghana Finally, W Pople of the Zoology Department, University of Ghana, gave a paper on "The Annual Cycle of a Lagoon in Ghana" He pointed out the features of the small blind estuaries of Ghana and described the annual features of the Kpeshi Lagoon of Accra

The afternoon session was chaired by O Snow, adviser on agricultural matters Dr W K Agble, deputy chief scientific officer, spoke on "Improvement of the Yields of Maize in Ghana" He reviewed the work done in this field since the adoption of a breeding programme on conventional lines as well as on emergent concepts of breeding tropical maize leading to the development of new synthetic hybrid maizes The next paper was that of Dr K Kadambi, formerly of the Indian Forestry Service, whose paper was read in his absence by Dr B J Harris It was on "Vegetative Propagation of Tropical Plants by Means of Air-layers" Finally, in this series was a paper by P Appiagyei-Danka of the Scientific Services Division on "Porosity Status of Some Major Soils of Ghana" The paper gave in much detail original investigations carried out by P Appiagyei-Danka on this vital aspect of the soil, and provided information that is much needed with the introduction of mechanization and intensive cropping throughout Ghana

The sessions for the day and for the whole conference were rounded off with a special short session of two papers read by two of the visiting scientists The first speaker was the 80-year-old Chilean experimental physiologist, Prof Alexjandro Lipschutz, who read a paper on "Some Progress with Hormones in Cancer Research—Experimental Aspects" The final speaker was Sir Robert Watson-Watt, who read a paper on "The Ethical Responsibilities of the Scientist" In the evening there was a film show

The final day of the conference, July 1, was devoted to excursions to Tema, Akosombo and Nungua Station The conference was rounded off with the annual dinner of the Association in the evening

There is no doubt that the second annual congress constitutes an improvement over the first one in many ways, particularly in respect of the participation of a number of leading scientists from other parts of the world Most of the papers read at the congress are to be published in the forthcoming issues of the *Ghana Journal of Science*

J Yanney-Wilson

THE TROPICAL PRODUCTS INSTITUTE

REPORT FOR 1961

DURING the next five years, the Department of Scientific and Industrial Research's Tropical Products Institute should expand its facilities to meet the increasing need for advice and investigatory work which is expected to result from technological and industrial development in tropical countries*.

Every year the Institute receives an increasing number of requests for specialist staff to visit tropical countries to give on-the-spot advice on problems connected with the use of natural products. The present commitments at the Institute often prevent the release of existing staff for this work. The Institute's Managing Committee considers that additional staff should be recruited so that experienced scientists will be available at relatively short notice for overseas investigations and, possibly, for the training of overseas laboratory staff in their own countries. Many tropical countries are beginning to set up their own research organizations with facilities for undertaking some investigations which previously would have been carried out at the Tropical Products Institute. However, the lack of suitable trained staff is still a problem, and it is recommended that opportunities for training them should be provided at the Institute in London.

The Director reports more than 960 inquiries for advice and assistance from 65 countries during 1961. About 20 per cent of these inquiries related to marketing, trade and economic aspects of various tropical commodities. A further 30 per cent were concerned with processing methods and machinery, packing, storage and transport and the capital, plant and labour required for the establishment of small industries.

Among the investigations was one which may lead to a new coffee industry in British Guiana. For the first time an 'instant coffee' has been made from Liberica coffee beans grown in British Guiana. This was done during an investigation to find out if a local 'instant coffee' industry could provide an additional market for the increasing production of Liberica coffee beans, almost the only remunerative crop that will grow in the peaty soils of the British Guiana plantations. Coffee infusions were prepared at the Tropical Products Institute from two blends of Liberica and Robusta coffees. The powders proved to be of good flavour, the objectionable tang normally associated with Liberica coffee being largely removed during the processing operations. It would seem, therefore, that an acceptable 'instant coffee' could be manufactured from this coffee bean, with or without the addition of Robusta coffee. As a result the British Guiana Government has asked the Institute to obtain an estimate of the cost of a machine to prepare 'instant coffee', and plans for a suitable factory building, including machinery layout.

Other research workers examined an African weed to see if it could be used as a new source of oil. The seeds of *Trichodesma zeylanicum* (a member of the borage family), which grows as a pernicious weed in many parts of Africa, and especially on maize farms in Northern Tanganyika, may now prove to be a commercial source of oil. Investigations have shown that the seed contains about 30 per cent of a drying oil, similar to linseed oil, which, if it could be produced economically, might be used in the paint, linoleum and leather industries. This oil content is low compared with major oil-producing crops such as groundnuts (about 50 per cent), copra (some 60 per cent), and linseed (about 40 per cent), but it might be improved by plant breeding, as has been done with linseed. As the seed contains supinine, an alkaloid which causes liver damage, the extracted meal is not suitable as an animal feeding material.

Cloves are Zanzibar's biggest export, providing about three-quarters of the world's supply. The islanders are largely dependent on this spice for their livelihood, and efforts have been made to find new uses for cloves so that the local economy can be improved. Clovebud oil, which is responsible for the aroma and flavour of cloves, is now being re-examined at the Tropical Products Institute with the use of new chemical techniques which may reveal the presence of components overlooked or wrongly identified in earlier analyses.

Although regular spraying of tea bushes with DDT is not a normal practice, it is important to know to what extent DDT persists in tea, both before and after processing, and in any infusion prepared from it, since such sprays are occasionally used. Research workers at the Tropical Products Institute have found that, while a large proportion of DDT present in the green leaf persisted throughout all stages of processing, only very low levels could be detected in infusions. This was so even when levels of DDT were much higher than those likely to be encountered in commercial practice. A similar study of sacks of whole root ginger, sprayed with DDT in Jamaica, showed that the levels of DDT persisting on the ginger after storage were sufficiently high to suggest that this insecticide should not be used for the protection of large stacks of ginger without further investigation. Tests with malathion, however, showed that the persistence of this insecticide was much lower than that of DDT and that contamination of stored ginger would be only slight if the insecticide were applied at normal rates.

Experiments at the Tropical Products Institute may lead also to a new industry in West and Central Africa, South America, India and other sub-tropical countries. Large quantities of groundnut shells, or husks, have no industrial use at present and disposal is difficult. They do not burn easily, nor do they rot quickly enough when returned to the land. Preliminary trials have produced an experimental particle board which is technically adequate and cheap to produce.

There are three important reasons why this industry could be developed in these countries with economic advantage. There is an abundant supply of the raw material in areas where there is often a shortage of low-priced building and furniture materials. No machinery would be required to reduce the shells to suitable sized particles, and the shells would be sufficiently dry when produced to be made into board without further drying. Preliminary trials are also in progress using rice hulls, coir waste, bagasse and other materials.

---

TRAINING OF BIOLOGISTS

A CONFERENCE arranged by the Institute of Biology to discuss the training of biologists in all spheres of their activity was held during April 17–18 at The Polytechnic, Regent Street, London

The problems discussed during the first session were largely those concerned with the early training of biologists in the schools The first speaker was Mr Hugh P Ramage, chairman of the panel which framed the proposals of the Science Masters' Association and the Association of Women Science Teachers[1] Their view was that all pupils should pursue a balanced course of scientific study up to the sixth form In the sixth form, regardless of their special aims, all should continue with a broad 'general study' of science, if they were scientists the detailed factual content of their Advanced Level courses should be reduced Dr L H Finlayson (University of Birmingham), discussing the Biology Panel report in the Gulbenkian inquiry[2], endorsed the view commonly shared that the separate disciplines of botany and zoology should be abandoned in favour of the single subject biology, this would allow better opportunity for young biologists to acquire essential collateral training in chemistry, physics and perhaps mathematics Both he and Mr D A Coult (University of Liverpool) discussed the as yet unconfirmed proposals of the Northern Universities Joint Matriculation Board Biology Panel for a syllabus in which a synthesis of these two reports had been attempted It had been accepted that the basic language of biology could well be taught by reference to mammals and flowering plants, but that thereafter the Northern Universities Joint Matriculation Board Panel had adopted (with modification) the Gulbenkian proposals, whereby essential biological principles were taught with complete freedom of choice of illustrative material on the teacher's part Only by this means could individual enthusiasms be encouraged, it was planned to provide fairly extensive notes to help teachers who needed more guidance Many speakers expressed anxiety about the text-book situation and the need not only for good 'narrative' accounts of biological fields in which exciting advances have been made, but also for help in teaching biology as an experimental science Considerable criticism was voiced about the value at this stage of the demand for detailed dissection of the rat It was pointed out that even if the demand for a detailed dissection could be justified, the rat was almost an economic necessity for all but the small examining bodies

Prof C T Ingold (Birkbeck College, London) and Prof B M Jones (Aberystwyth) discussed university requirements for entry into botanical and zoological departments respectively Both agreed that most freshmen would be all the more acceptable for having received some training in mathematics and the physical sciences in addition to biology, but that it would always be a pity if this precluded entry for the naturalist with no aptitude for the physical group of sciences Both agreed also that a wide spread of at least three, if not four, Advanced Level subjects was desirable, and, should this prove too great a load, the proper remedy was surely to reduce the factual content of syllabuses Prof Jones, supported by Dr S. J Pirt (Queen Elizabeth College, London), advocated the reintroduction of subjects at a lower level (effectively the old subsidiary level of the Higher School Certificate) in order to make the spread more realizable It was greatly to be hoped that by this means sixth-form pupils with a flair for chemistry and physics could also be introduced to biology

The second session of the conference was concerned with the teaching of biology in the universities, and was opened by Prof J W S Pringle (Oxford), who analysed the problems of teaching in twenty-nine departments of zoology Variations were to be seen in respect of exemption from first-year work on the basis of good Advanced Level qualifications, and on the amount of specialization allowed in the last (third or fourth) year of the course Generally speaking, he said, a measure of specialization was found inevitable, but should never be allowed to prejudice the essentially broad training for a first degree Nevertheless, comparative anatomy should always leave time for teaching those non-taxonomic aspects of zoology which gave true integration to the course The problem, as he saw it, was to reconcile the slower-moving evolutionary studies, attractive to the naturalists, with the newer experimental fields in which the pace is at present being set He then outlined the projected first-year biology course at Oxford, which includes physics, chemistry and geology for biologists, who in their own right also take a course including genetics, general physiology, taxonomy, evolution and ecology This can then lead on in subsequent years to more specialized studies of plants and animals, of which systematic study is only one aspect It was planned also to provide for instruction in biology to postgraduate physicists and chemists

Prof W O James (Imperial College of Science and Technology, London) said that his Botany Department was concerned with the training not only of teachers and botanical technologists and the research workers of to-morrow, but also of those who were unlikely to become professional botanists He spoke strongly in favour of catering more meaningfully for the needs of our teachers, as for potential professional botanists, he pointed out that training must make it possible for such students to understand the language of the cognate sciences, so that communication and co-operation between the sciences might become more fruitful He was not in favour of a special project in the final year, which as low-grade research often got out of hand, but preferred the student to make a choice of one out of three options, namely, ecology with taxonomy, physiology with plant biochemistry, and mycology with plant pathology All such options also involved advanced formal teaching and long-term practical work

Prof H E Street (University College of Swansea) turned to consider the postgraduate training of biologists He strongly criticized the system of three years' training for a doctorate, first, in that it did not involve enough compulsory formal tuition and, second, because there was such a high pass-rate He did not believe in the attitude of 'sink or swim' for postgraduates any more than he believed in boosting a poor performance, at the last, with all the skills of the supervisor, a middle course was infinitely preferable He would prefer to see the Ph D candidate selected after an M Sc year consisting of broadly based formal teaching and an initiation into research, and he deplored the fact that too many candidates with 'lower seconds' were being given postgraduate degrees or diplomas in topics such as microbiology and biochemistry, etc , on the basis of formal tuition alone Prof D J Carr (Queen's, Belfast) thought that Prof Street's views might not easily apply to small departments Dr K Mellanby (Nature Conservancy) thought that suitable research stations might play quite an important part in postgraduate training Prof A H Bunting (University of Reading) asked for a better liaison between schools, universities and research institutions in order to promote better vocational orientation toward the satisfying careers available especially in applied biology Mr T A Oxley (Civil Service Commission) directed attention to the fact that students could gain valuable experience by taking vacation jobs in Government research establishments, while at a higher level a research fellowship scheme was operated Details of these could be found in a pamphlet recently published by the Civil Service Commissioners and entitled *The Scientific Civil Service*

The third session, held on the morning of April 18, fell into two parts Mr H Tristram (University College, London) spoke first on the teaching of microbiology in the universities He thought that there was some justification for a first degree in microbiology, provided that micro-organisms were used to illustrate the fundamental properties of living organisms, and that a full coverage of all types of micro-organisms was available, cutting across all the traditional boundaries He emphasized the value of micro-organisms in biochemical teaching, each organism, too, occupied its own ecological niche and demanded a 'naturalist' approach Practical work should concern itself with fundamental principles, and with experimental techniques which were a means to an end, and not an end in themselves Entrance requirements for such courses as exist all show a demand for initial training in chemistry, and for preference also in physics and mathematics Dr S J Pirt (Queen Elizabeth College, London) in a joint paper with Dr J R Postgate (Microbiological Research Establishment, Porton) discussed the desirable training for research in economic microbiology Having outlined the scope of economic microbiology, he underlined Mr Tristram's case for non-medical microbiology as a separate and specialized discipline, rather than as a branch of botany Posts available up to now had largely been filled by chemists, who picked up their microbiology second-hand A proper training course was to be preferred and should include advanced instruction in chemistry and the physical principles appropriate to aseptic engineering techniques, and enough mathematics to handle quantitative data and to design experiments that could be statistically controlled He deprecated ancillary training in the macrobiological aspects of botany and zoology, while welcoming the comparative biochemistry of higher plants and animals To the microbiological disciplines advocated by the first speaker he would add the techniques of tissue culture, and he thought that optional courses in microbial genetics, cytology and ecology would be indispensable The evolution of microbiology was fast and exciting, and it demanded a considerable flexibility of approach for the solution of its problems Prof D G Catcheside (University of Birmingham) thought that, as time was so limited, each course in whatever department should be built around a theme In Birmingham, for example, microbiology was developed about the theme of the genetic material and its expression As to the demand for more physics, chemistry and mathematics in biology, he thought that biologists without such training would be squeezed out of a larger increasing part of biology

Mr J B Copp (general secretary, Institute of Biology) discussed the means whereby biological laboratory assistants in industry and Government service might proceed by an alternative route to full professional status as biologists At present there were two levels, Ordinary and Higher, of the National Certificate Since 1957 the Ministry of Education has joined with the Institute in endorsing these certificates for biology In Scotland candidates have been able to sit for National Certificate examinations in biology since 1961 In England it is proposed to replace the Ordinary National Certificates at present available in scientific subjects with a generalized Ordinary National Certificate in Science The Ministry has been asked to introduce a Higher National Certificate in biology for subsequent training of those specializing in biology

Dr T G Onions (Brunel College of Technology) reviewed the institution and progress of the Diploma in Technology in applied biology This Diploma was open to entry both from schools ('college-based students') and from biological industry ('industry-based students') The first group predominated and received some of their training with the active co-operation of industry though as yet industry was not sending many of its own employees for sandwich courses The academic course was completed by a project and thesis, often the result of ideas stimulated by work with the host organization

Dr Onions commented on the need for liberal studies during this period and especially for continued training in the writing of good English He pointed out that the Diploma in Technology was intended to have the equivalent of graduate status, whether for purposes of proceeding to higher degrees, for full membership of the Institute of Biology, or generally for grading in the Scientific Civil Service

In discussion at the end of this period, a variety of opinions was expressed about the proposed Ordinary National Certificate in Science so far as biology, now much reduced in content, was concerned Mr D O Weitzel (Coventry Technical College) felt that a complete revision of syllabuses was required at both Ordinary and Higher Levels Mr E Norris (Ewell County Technical College) suggested a synthesis in which a good background of chemistry, physics, mathematics and English was deliberately slanted towards biology, even though specialization in biology itself was deferred to a later level It might, however, be necessary, he said, to combine this early general training with a general qualification in biological technology

The final session was opened by Mr T A Oxley (deputy commissioner, Civil Service Commission), who dealt with the requirements of the Civil Service for biologists He explained the classification of scientific officer, experimental officer and scientific assistant, pointing out that these categories were also in use in the Nature Conservancy and the Agricultural Research Council, although these bodies were strictly separate from the Scientific Civil Service He gave an analysis of the distribution of biologists of all grades throughout the various Governmental services He commented on the greater degree of specialization among biologists, which made it more difficult for them to change their field of employment than for, say, physicists He urged the importance of training in clear thinking and writing of reports There was a difficulty, he said, in persuading physicists or mathematicians to enter biological research teams, and one remedy would be for biologists with the appropriate flair to read a second degree in either subject

Prof F L Milthorpe (University of Nottingham) followed with a paper on the type of training suitable for agricultural research He sketched out the ramifications of the whole agricultural system and stressed the need in a successful course for presenting the basic principles of each of the interrelated disciplines, while keeping the integrated complex in mind The need for the use of teachers of so many disciplines helped to avoid the inbred narrowness of botany and zoology As for postgraduate training, he was certain that such training should be by research, that recruitment was to be preferred from a lower level such as plant physiology into a higher level such as agronomy, and lastly, that projects framing a very restricted part of an extensive programme are rarely satisfactory for training in research

Dr F Kingsley Sanders (director Medical Research Council Virus Research Unit) gave his views on the necessary qualifications for research in virology and molecular biology Biologists appeared to occupy a rather lowly position in his scheme for selection, unless they had undergone considerable training in physics beforehand

The final contribution from Dr W A Bain (Smith, Kline and French) dealt with the use of biologists in research and development in the pharmaceutical industry He thought that pharmacologists were in particularly short supply Working conditions in industry, he said, compared very favourably with those in universities, both in respect of emoluments, equipment and promotion prospects He paid tribute to the work of the biological technicians, and voiced the view that industrial firms were less liable to make the mistake of the universities, who had largely failed to appreciate the importance of technical staff in their scientific departments He congratulated the Institute of Biology, which, in conjunction with the Ministry of Education, had promoted the Higher Endorsed Certificate in biology, which should prove invaluable in this field

In the discussion at the end of the fourth session, disquiet was expressed that in the specialist demand for chemistry, physics and mathematics, biology would be even more than at the present squeezed out of its rightful place in the school Dr J C Smyth (Paisley Technical College) thought that the Institute's most important task was to improve the public image of biology, especially in the schools, by presenting it as a more rigorous scientific discipline Mr D O Weitzel (Coventry Technical College) thought that an Advanced Level course of 'background science for biologists' would meet the needs of the schools better than training in Advanced Level mathematics, physics and chemistry

Mr R Weatherall (Avery Hill Training College) spoke of the need for research into the whole educational process Were it more possible with the aid of the educational psychologists to detect and train real scientific ability, the way would be open for the already urgent reform of the examination system, which in its turn would bring more freedom at all levels to scientific teaching

The conference was well attended throughout and it was abundantly clear that there is a widespread and lively interest in improving the ways and means of training all categories of biologists during this present explosive period of expansion in biology

ASPERGILLUS FLAVUS AND TURKEY X DISEASE

Isolation in Crystalline Form of a Toxin responsible for Turkey X Disease

THE toxin responsible for the so-called Turkey *X* disease has been described by Sargeant *et al* [1] as a metabolite of the mould *Aspergillus flavus* Link ex Fries Elsewhere[2] we have described the examination by thin-layer chromatography of toxin-containing extracts of groundnut meals and cultures of *Aspergillus flavus*, and presented evidence which suggests that such extracts may contain more than one substance toxic to ducklings This communication is concerned with the isolation in crystalline form of one of these substances from cultures of *Aspergillus flavus*, and gives an account of some of its physico-chemical properties

Mould cultures grown on a medium of wetted, crushed sterile groundnuts were extracted with chloroform/methanol (2 1), and the residue remaining after evaporation of the solvent defatted by partition between 90 per cent aqueous methanol and light petroleum The methanol-soluble material was chromatographed on a column of 'Silicagel' ('Mallinckrodt') in chloroform/1 per cent ethanol, and the zone fluorescent in ultra-violet light further purified by thin-layer chromatography on 'Kieselgel *G*' (Merck), column chromatography over 'Kieselgel *G*'/'Celite', and finally, filtration through a short column of alumina After crystallization from chloroform/ethanol, the recovered material was obtained as gleaming, almost colourless, anisotropic, monoclinic platelets (Fig 1) which had no sharp melting-point but decomposed at about 220° C Seventy-two chromatoplates yielded 40 mg

The same substance, which pending complete structural characterization we refer to as FB_1, was more simply isolated from liquid cultures of the mould in glucose/ammonium nitrate medium Chromatography of a chloroform extract of the culture medium

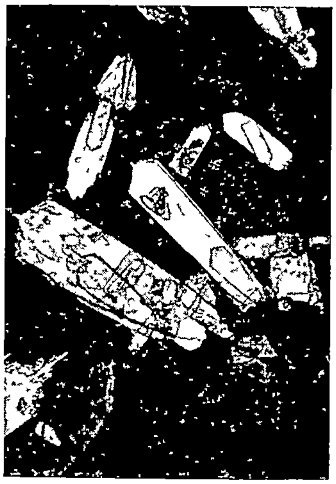

Fig 1 Crystalline toxin (× c 84)

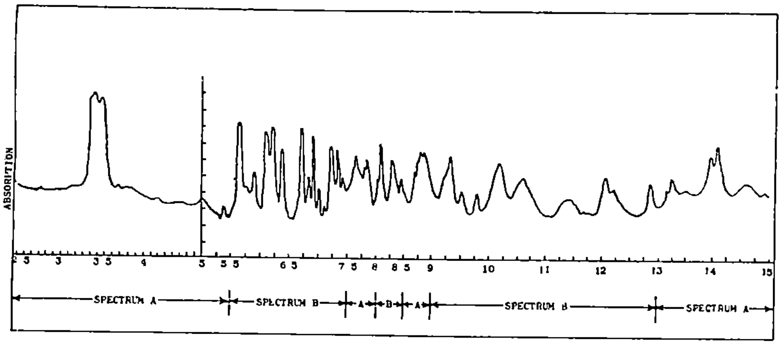

Fig 2 Infra-red absorption spectrum of fraction FB_1

State of sample

(*A*) Mulled in nujol	(*B*) in bromoform
2 5 μ–5 5 μ	5 5 μ–7 5 μ
7 5 μ–8 0 μ	8 0 μ–8 5 μ
8 5 μ–9 0 μ	9 0 μ–13 μ
13 0 μ–15 μ	

on a column of a 'Kieselgel *G*'/'Celite', developed with chloroform containing 0 25 per cent ethanol, provided a fraction which exhibited a blue-violet fluorescence in ultra-violet light, and which gave a single fluorescent spot on a chromatoplate coated with 'Kieselgel *G*' Evaporation of the solvent yielded a residue which readily crystallized from chloroform/ethanol, this crystalline substance was identical with FB_1 obtained from cultures on groundnut medium

The LD_{50} value of FB_1 to ducklings (one-day old Peking ducklings), 55 g mean body-weight, single dose (observed for 48 h), was 30–50 μg

Infra-red, nuclear magnetic resonance, and ultra-violet absorption spectra of FB_1 are shown in Figs 2–4, *E* (1 per cent, 1 cm) at λ_{max} 360 mμ was calculated to be 660

Under certain conditions, FB_1 is apparently photosensitive. In hydroxylic solvents such as water, methanol, ethanol, acetic acid, and particularly in the presence of oxygen, irradiation with ultra-violet light caused fading of the fluorescence, and a change in the ultra-violet absorption spectrum The change brought about by brief exposure is shown in Fig 4, curve II, prolonged exposure resulted in the disappearance of the peak at 360 mμ Moreover, solutions of FB_1 in these solvents which before irradiation gave a single spot on a chromatoplate afterwards were resolved into several additional fluorescent spots of lower R_F values

Treatment of FB_1 with alkali caused a shift of λ_{max} 360 mμ to λ_{max} 370 mμ, the shift being reversible on immediate acidification For the irradiated material, the shift was from λ_{max} 353 mμ to λ_{max} 401 mμ, this change was reversible on immediate acidification, but after prolonged contact with alkali, the peak at 401 mμ disappeared, and the 353 mμ maximum was not regenerated on acidification

The interpretation of ultra-violet, infra-red and nuclear magnetic resonance and mass spectroscopic results (and certain chemical data not reported here) in terms of chemical structure is in hand

We thank the Central Veterinary Laboratory, Ministry of Agriculture, Fisheries and Food, Wey-

bridge, for the supply of cultures of *Aspergillus flavus*, and for extracts of cultures grown in liquid medium.

Note added in proof. Since submitting this communication we have obtained evidence, as a result of isolating larger quantities of material, that the crystalline toxin still contains some impurities. This evidence is from ultra-violet absorption spectra and from mass spectrometry, and will be described in a later communication.

Toxic Metabolites of *Aspergillus flavus*

Further work has been carried out on the purification and characterization of the toxin produced by certain strains of *Aspergillus flavus* and described by Sargeant *et al.*[1]

The fluorescent material which was described as running on paper in *n*-butanol–acetic acid at R_F 0·7 has been further resolved on alumina chromatoplates in 98·5 per cent chloroform/1·5 per cent methanol[2]. Two spots which fluoresce in ultra-violet light are obtained, one running at R_F approximately 0·6 and having a violet-blue fluorescence and the other running slightly more slowly and having a green fluorescence. For convenience, these are referred to as Aflatoxin '*B*' and Aflatoxin '*G*' respectively.

Mixtures of these two compounds in varying proportions have been obtained both from sterilized groundnuts inoculated with the toxic strain of *A. flavus* and from Czapek's Dox medium with added zinc sulphate on which the fungus had been grown for 5–7 days at 27° C. The toxic mixture was isolated from the nuts by extraction with hot methanol, the methanolic extract was then concentrated, diluted with water and defatted with 40°–60° petroleum ether. The methanol was distilled off and the toxin extracted into chloroform, the chloroform extract was concentrated and passed down a column of silica gel. The fluorescent fraction from the column was evaporated to dryness under reduced pressure and the residue recrystallized from benzene or methanol. Crude crystalline toxin was obtained from the synthetic culture by direct extraction with cold chloroform, followed by chromatography of the concentrated chloroform extract on silica gel.

Aflatoxins '*B*' and '*G*' have been separated from one another by counter-current distribution in chloroform/carbon tetrachloride/water/methanol, 2 : 2·5 : 1 : 3 (200 transfers). After recrystallization from methanol, Aflatoxin '*B*' was obtained as irregularly shaped plates which melted with decomposition at about 270° C with prior softening at 250°–260° C. Elementary analysis gave C = 65·6, H = 4·4, O = 30·9 per cent and mass spectrometric examination gave 312 or 314 for the molecular weight. $C_{17}H_{12}O_6$ requires C = 65·4, H = 3·9, O = 30·7 per cent, mol. wt. 312. The ultra-violet spectrum showed peaks with maxima at 223 mμ, 265 mμ and 363 mμ, the molar extinction coefficients being 23,400, 12,700 and 20,500 respectively (assuming a molecular weight of 312). (In earlier work, blue fluorescent material was obtained with higher molar extinction coefficients for the ultra-violet peaks, in particular $\varepsilon_{363\ m\mu} = 44,500$. The other characteristics of this material were closely similar to those of Aflatoxin '*B*'.) The fluorescence spectrum showed a peak at 429 mμ, the absorption peak at 363 mμ in the ultra-violet being the excitation peak for this fluorescence. The infra-red spectrum in chloroform indicated that OH groups were absent, unless chelated; there were two peaks in the carbonyl region at 1,755 cm⁻¹ and 1,688 cm⁻¹. Measurement of optical rotation in chloroform gave $[\alpha]^{25}_{D} = -562 \pm 15$ ($c = 0·115$).

Preliminary biological tests on day-old ducklings indicate an LD_{50} of less than 20 μg.

Aflatoxin '*G*' has been purified by rapid filtration through a column of acid alumina and repeated recrystallization from methanol, giving fine, colourless needles with melting-point 247°–250° C. Elementary analysis gave C = 61·8, H = 4·0, O = 34·4 per cent, and mass spectrometric examination indicated a mol. wt. of either 326 or 328. $C_{17}H_{12}O_7$ requires C = 62·2, H = 3·7, O = 34·1 per cent and mol. wt. 328. The infra-red spectrum was closely similar to that of Aflatoxin '*B*', the major difference being a shift of a peak at approximately 1,125–1,140 cm⁻¹. The ultra-violet absorption spectrum has peaks with maxima at 265 mμ and 363 mμ (molar extinction coefficients 10,500 and 18,700 respectively, assuming a mol. wt. of 328). The fluorescence peak is at a slightly longer wave-length (450 mμ) than that of Aflatoxin '*B*'. The value for the optical rotation, $[\alpha]^{25}_{D}$, was -533 ± 5 ($c = 0·133$).

Biological tests on day-old ducklings indicate an LD_{50} of about 60 μg for this material

Work is in progress on the further characterization of the compounds described and on the elucidation of their structures

We thank Mr R B A Carnaghan of the Central Veterinary Laboratory for the biological tests Miss H Brown for technical assistance, Dr R I Reed of the University of Glasgow and Dr H Powell of the British Petroleum Research Centre for mass spectrometric determinations and Dr V Thaller of the University of Oxford for the measurement of optical rotations

Note added in proof. Since submitting this communication we have obtained evidence that Aflatoxin '*B*' is a mixture of two closely similar compounds

LOSS OF INFECTIVITY ON DRYING VARIOUS VIRUSES

By F. E BUCKLAND and D A J TYRRELL

Medical Research Council, Common Cold Research Unit, Salisbury

ALTHOUGH certain viruses survive drying in air, others do not, and it has been shown recently by Hemmes, Winkler and Kool[1] that the survival of the latter is affected by the relative humidity of the air Poliomyelitis virus type 1 and one strain of influenza virus type *A* were sprayed into a chamber and the rate of decline of infectivity was measured The rate of poliovirus decline was low in air of a relative humidity greater than 50 per cent but higher in drier air the rate for influenza virus was low when the relative humidity was below 40 per cent and high when it was above 50 per cent These observations have in general been confirmed by Harper[2]

We have examined the effect of drying a number of viruses by means of a much simplified method Viruses were grown in eggs or in tissue culture and for test were suspended in or diluted in 2 per cent calf serum and 0 25 per cent lactalbumin hydrolysate in Hanks's saline containing 0 09 per cent sodium bicarbonate and antibiotics Twenty 0 0001 ml drops of the suspension were distributed with a microsyringe on each of four clean glass slides which were put at once into (*a*) a desiccator containing a saturated solution of potassium acetate (relative humidity of air 20 per cent at 20°), (*b*) a desiccator containing a saturated solution of potassium bromide (relative humidity of air 84 per cent at 20°), (*c*) a Petri dish containing wet filter paper maintained at room temperature (as were *a* and *b*), (*d*) a similar Petri dish kept at 4°

After 2½ h, the drops in *a* and *b* had dried while those in *c* and *d* were wet The slides were then washed down thoroughly with 1 ml of suspending medium and this was immediately titrated for infectivity the influenza viruses were titrated in embryonated eggs and the other viruses in tissue cultures

Preliminary experiments showed that no detectable virus was lost on to the slide by this procedure, whereas there were considerable losses if the drops were spread on cotton, or nylon

The results of a representative experiment are summarized in Table 1 The titres in *c* and *d* were usually very close, but we detected marked thermal inactivation of RS (respiratory syncytial) virus at room temperature under these conditions and so this virus was not studied further Experiments were usually repeated two or three times and the results are given in Table 2 This shows that although conditions of drying were different from those used by Hemmes *et al* we were in general able to confirm their results, in that the infectivity of all three serotypes of poliovirus was more unstable at 20 per cent relative humidity than at 84 per cent relative humidity, the other six enteroviruses tested gave a similar result Strains of influenza *A* were, on the other hand, more stable at low relative humidity

Rhinoviruses and adenoviruses behaved like enteroviruses and survived better at high relative humidity Parinfluenza and *REO* viruses survived as well at high as at low relative humidity The arbor virus we tested seemed to survive best at low relative humidity but this result must be viewed with caution since Harper's data (his Table 1) suggest that the arbor virus he studied (*VEE*) survived best at high relative humidity up to 4 h and at low relative humidity afterwards We note that the viruses that

lack lipids, namely, enteroviruses and adenoviruses, all survived best at high relative humidity while those which have lipid components, namely, influenza viruses and the arbor virus, survive best at low relative humidity The method seems, therefore, to subdivide the viruses we tested into the same groups as the ether sensitivity test[3], although the results with parainfluenza and *REO* viruses are indeterminate However, vaccinia is ether stable and Harper[2] found that it survived better at low than at high relative humidity His data also show (Table 1) that at relative humidity 50 per cent inactivation of poliovirus was more complete and rapid than at relative humidity 35 per cent or 65 per cent It is of interest that some viruses which survive less well at low relative humidity, for example, poliovirus, cannot be successfully freeze dried, while others, for example, adenovirus, can It is clear, therefore, that it is premature to suggest physiochemical explanations for these phenomena

Hemmes *et al* suggested that the survival of viruses at high and low humidities might account for their seasonal prevalence In winter, when the relative humidity indoors became low because the air was artificially heated, poliovirus would survive badly This difference might account for the prevalence of influenza in winter and of poliovirus in summer We consider that the effect of relative humidity on virus survival may indeed influence seasonal prevalence but it cannot determine it completely, for Table 2 shows that some respiratory viruses such as *B*633 [4] and adenovirus type 3, which are particularly common in the cold months of the year, have a stability pattern like that of poliovirus In addition, Hemmes *et al* calculated, from the recorded outdoor humidities and the temperatures indoors and outdoors, that indoor humidities of 40 per cent occurred in Britain in the winter This, however, does not take account of the water vapour produced by human beings and by domestic activities In the winter of 1960–61 the lowest relative humidity recorded in this centrally heated laboratory was 47 per cent In a centrally heated house nearby the relative humidity was between 50 and 60 per cent Similar findings have been reported by Hope-Simpson[5] In the exceptionally cold dry spell in March 1962 measurements in a centrally heated house and in the kitchen of a cottage heated by a range showed a relative humidity that never fell below 40 per cent Readings taken in the local theatre at that time showed that the relative humidity rose from 46 to 53 per cent during a performance and fell back to 45 per cent in 15 min when the theatre emptied Hutcheon[6] has shown that even in the Canadian winter the relative humidity inside a house may be much higher than that calculated from conditions outdoors It is therefore probable that in Britain, except in unusually dry cold winters, the relative humidity in living rooms and public places, where virus transmission probably takes place, rarely falls below 50 per cent, the level at which the factors demonstrated by Hemmes *et al* may be expected to operate

It is possible that changes in relative humidity affect the reaction of the host to virus infections, but we feel that in future any attempt to make a complete analysis of the effect of the environment on the epidemiology of a virus will have to include the demonstrated effect of relative humidity on virus survival outside the body We thank Dr D Taylor-Robinson for help in certain experiments

EFFECT OF THE MATERNAL ENVIRONMENT ON STRAIN-SPECIFIC DIFFERENCES IN THE OVARIES OF NEW-BORN MICE

By DR ESTHER C JONES and PROF P L KROHN*

Department of Anatomy, The Medical School,
Birmingham, 15

WE[1] have reported that inbred strains of mice differ widely in the stage of development reached by their ovaries at the time of birth Thus, most of the oocytes in *CBA* strain ovaries have already entered the dictyate stage whereas in *A* strain ovaries the majority of oocytes are still in meiotic prophase The question arises whether these strain differences are due to inherent differences in the ovaries themselves or whether the maternal environment in which the ovaries develop can influence the course of oogenesis One way of analysing the problem would be to examine the stage of ovarian development reached at birth by mice derived from fertilized eggs of one strain transferred to the Fallopian tube or uterus of the other An alternative is to use orthotopic transplantation of the ovaries from one strain to another to produce pure-strain litters from genetically alien mothers[2] The discovery of methods of inducing immunological tolerance[3] has made it possible to overcome the obstacles which the homograft reaction ordinarily places in the way of this approach, and we have preferred it, since it allows the oocytes before ovulation, as well as the ova after ovulation, to develop in the foreign environment

CBA female mice have, therefore, been made immunologically tolerant of *A* strain tissues and vice versa, by the usual technique of injecting an appropriate spleen cell suspension either intraperitoneally or intravenously into the new-born The foreign ovaries were transplanted orthotopically[4] as soon as a test skin graft on the host revealed a state of complete tolerance (survival in perfect condition for 75 days) After recovery from the operation, *A* strain hosts were first test-mated with an *A* strain male, to provide a colour marker check that ovariectomy of the host had been complete,

and were afterwards mated with a *CBA* male to produce pure *CBA* offspring This preliminary step was unnecessary for the *CBA* female hosts bearing *A* ovaries, since any remaining *CBA* ovarian tissue would immediately reveal itself in the form of agouti hybrid offspring from the mating with an *A* male Once the experiment was under way, the females of the first litters born provided donor ovaries for further transplants to other tolerant mice and the males were used for mating with these later generations The general scheme is laid out in Fig 1

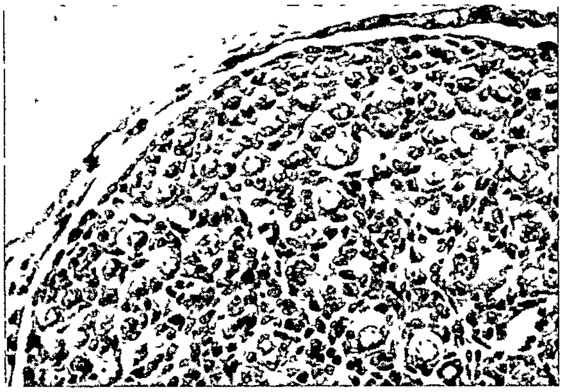

Fig 2 Ovary of a normal new-born *CBA* mouse (× *c* 100)

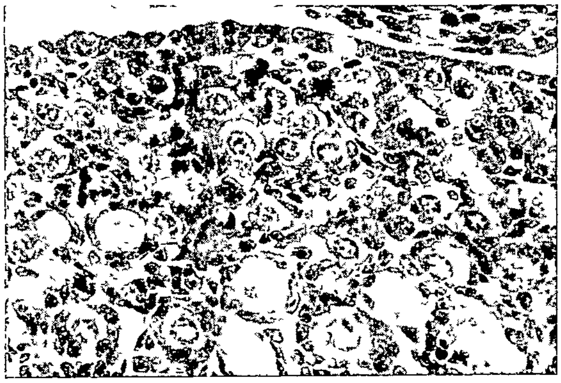

Fig 3 Ovary of a new-born *CBA* mouse derived from a *CBA* strain ovary transplanted into a tolerant *A* strain mouse (× *c* 100)

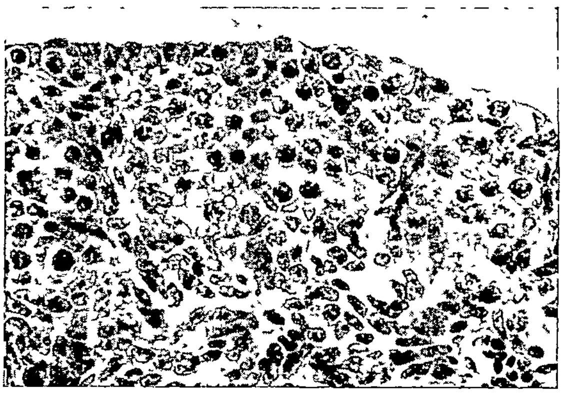

Fig 4 Ovary of a normal new-born *A* mouse. (× *c* 100)

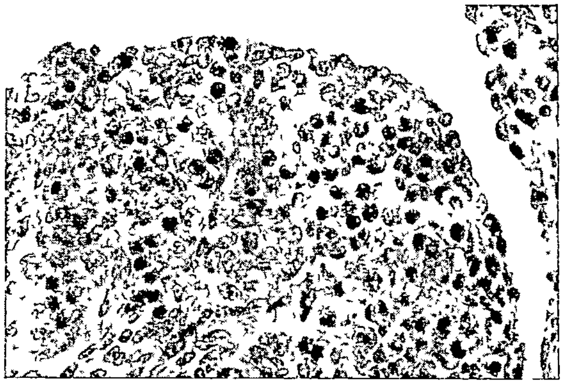

Fig 5 Ovary of a new-born *A* mouse derived from an *A* strain ovary transplanted into a tolerant *CBA* strain mouse (× *c* 100)

Seven *CBA* strain and 7 *A* strain female offspring from these immunologically tolerant mothers were killed immediately after birth and the ovaries removed and fixed Serial sections were prepared and counts made on the coded slides of the total number of oocytes, the proportion of normal to atretic cells and the proportion which were still in meiotic prophase The general histological appearance was always unequivocally that of normal *A* strain or of *CBA* strain ovaries, using the presence or absence of a large proportion of meiotic figures to divide the slides into two categories These observations, together with the results of the counts (Table 1), show that all the ovaries from new-born genetically *A* strain mice were entirely *A*-like and had been unaffected by the *CBA* environment The same was true of *CBA* ovaries, which all remained *CBA*-like (Figs 2–5)

The offspring, the ovaries of which have been examined, derived from ova which developed from the primary oocyte stage after the first transplantation, or the germ cell precursors in the second and subsequent passages, in a foreign environment Apart from the possibility of endocrine differences between strains, which might have altered the rate

Table 1 NUMBERS AND CONDITION OF OOCYTES IN THE OVARIES OF NEW-BORN *CBA* AND *A* STRAIN MICE

Strain	Environment	No of mice	Total oocytes	Normal oocytes (per cent)	Pre-dictyate oocytes (per cent)
CBA	*CBA*	3	10,900	87	55
CBA	*A*	7	10,700	85	55
A	*CBA*	7	21,100	90	93
A	*A*	8	17,200	87	91

of development of the ovaries, there are considerable opportunities during maturation and growth of the follicle for the transfer of large molecules (possibly strain specific) from the host's blood vessels to the oocytes in the grafted ovary via the closely apposed and interdigitating surfaces of granulosa cells and egg[5], and transfer could possibly have continued after fertilization both in the tube and in the uterus There are no indications, however, that even passage of *CBA* ovaries through six generations of tolerant *A* hosts has modified the specific pattern of development of the offspring Failure to show any effect also rules out the *a priori* possibility that the usual strain differences depend on differences in gestation time and hence of post-conceptional age at the time of birth

It may be concluded that even prolonged and repeated sojourn in the environment provided by a foreign strain cannot modify the pattern of oogenesis This retention of specific characteristics has also been observed for the histocompatibility antigens which determine the fate of grafted tissues Six members of earlier generations of *CBA* offspring and 13 members of the most recent generations have been tested with *A* strain skin to see whether the normal homograft reaction had been at all modified There has been no detectable deviation from the normal response Transplants of skin from the experimental *CBA* mice to 16 normal *A* strain mice have also been destroyed in the usual way

MODIFICATION OF THE STRUCTURE OF HÆMOGLOBIN BY CHLORAMBUCIL

By J. H. LINFORD

Department of Biochemistry, University of Manitoba, Winnipeg

A RECENT report[1], concerning changes that have occurred in the *p*K of the carboxyl groups in protein as a result of acetylation of a large proportion of the amino-groups, directed attention to the lack of data concerning the effect of chemical modification of a protein on the electrical character of the molecule In this connexion it may be of interest to recount an investigation into the reaction with hæmoglobin of *p*-N, N-di (β-chorethyl) aminophenylbutyric acid (chlorambucil), as it has been shown[2-4] that the carboxyl groups in protein are esterified by this compound Hæmoglobin, molecular weight 64,450, contains 8 38 × 10^{-7} equivalent of acid carboxyl groups per mg[5] Chlorambucil, molecular weight 304, contains 65 8 × 10^{-7} equivalent of reactive chloro groups per mg, 25 mg of the latter is therefore equivalent to 196 mg of hæmoglobin

Solutions of human adult hæmoglobin which contained 1,000 mg of hæmoglobin. and which contained 300 mg of hæmoglobin, were prepared Chlorambucil solutions were prepared at 5° C by dissolving 25 mg of the compound in 3 5 ml of 0 025 N sodium hydroxide The solutions of chlorambucil and of hæmoglobin were mixed together and adjusted to the required *p*H with the 0 025 N alkali The volume was made up to 20 ml with water and the mixture was shaken at 37° C Control mixtures of the same concentrations of hæmoglobin only were prepared, adjusted to the required *p*H, and shaken at 37° C At measured intervals of time, the *p*H was adjusted to the initial value by addition of measured volumes of the standard alkali, as shown in Fig 1

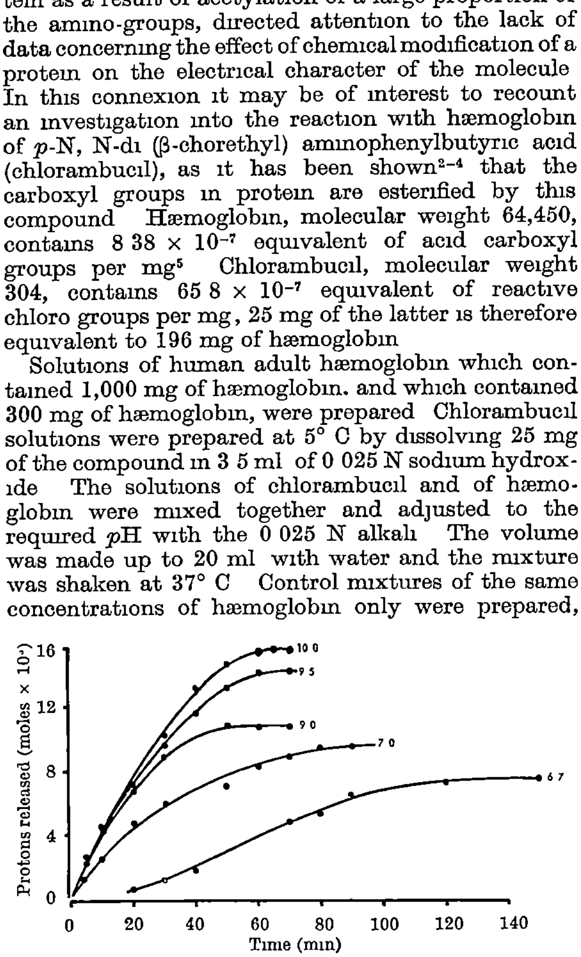

Fig 1 Rate of release of protons from 1,000 mg of human adult hæmoglobin during reaction with 16 4 × 10^{-5} moles (25 mg) of chlorambucil Numbers refer to *p*H values

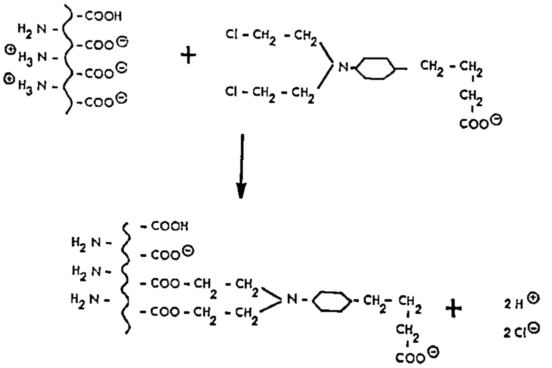

Fig 2 Diagrammatic representation of the reaction of protein with chlorambucil

Above *p*H 8 0 an appreciable change occurred in the *p*H value of the control solutions At *p*H 10 the corrected total amount of added alkali was 16 × 10^{-5} equivalent The 25 mg quantity of chlorambucil present was 16 4 × 10^{-5} equivalent It may be inferred that the esterification reaction at *p*H 10 0 was accompanied by the release of two hydrogen ions from protonated basic groups for each molecule of chlorambucil that was utilized (Fig 2) At *p*H 9 5 and below, dissociation of the basic groups was incomplete relative to the number of modified carboxyl groups

The control solutions and those containing the esterified protein were evaporated by freeze-drying, and each residue was dissolved in 5 ml of 0 15 M potassium chloride The protein which was precipitated by the addition of 8 volumes of ethanol was separated by centrifuge and was dissolved in 5 0 ml of N/5 hydrochloric acid Each acid solution was then back-titrated with 0 080 N sodium hydroxide The protonation of the protein that was esterified at *p*H 10 0 required one more equivalent of acid per mole of combined chlorambucil than was the case with the unmodified control protein (Fig. 3). At pH 9.5 and below, the amount of acid used for protonation was decreased in proportion to the reduced ionization of the charged basic groups. The amounts of chlorambucil remaining in the supernatant alcohol solutions were measured[6]. In the presence of 1,000 mg of hæmoglobin, 2 per cent of the chlorambucil remained in the uncombined reactive form; in the presence of 300 mg of hæmoglobin 2 per cent of chlorambucil was recovered in the reactive form and a further 8 per cent was recovered in the hydrolysed form. The basic groups from which the hydrogen ions were released were almost certainly the guanidyl groups in arginine, or the amino-groups of lysine, which have pK values of 12.5 and 10.5. The percentages of charged basic groups that dissociate per equivalent of modified carboxyl groups are plotted against the pH of the solutions in Fig. 4, which shows that the degree of dissociation of the affected groups approached 50 per cent at pH values near 7. The shape of the curve indicates that the degree of dissociation was directly proportional to the concentration of hydroxyl ion in the solution.

Reduction of the amount of hæmoglobin to 300 mg led to an apparently greater degree of dissociation of the charged basic groups at a given pH (Fig. 4). However, this apparent increase is accounted for by the amount of acid released during the hydrolysis of the chlorambucil. Therefore, over the range of equivalent ratios of hæmoglobin to chlorambucil from 5 : 1 to 1.5 : 1, the same change in pK occurs in certain charged basic groups which are equivalent in number to the amount of combined chlorambucil.

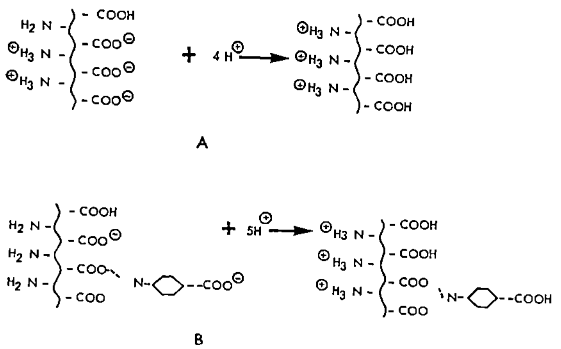

Fig. 3. Diagrammatic representation of the reaction of hydrogen ion with (*A*) protein, and (*B*) protein combined with chlorambucil

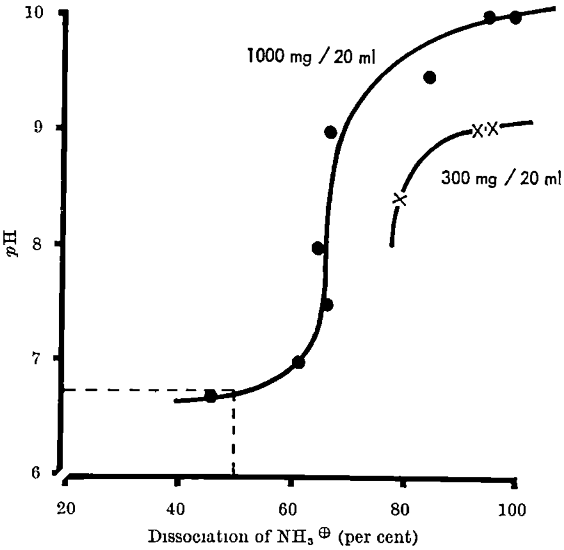

Fig. 4. Curve showing the relationship between the pH of the reacting mixture and the per cent dissociation of charged basic groups of hæmoglobin relative to the number of equivalents of combined chlorambucil

AMINO-ACID COMPOSITION OF GRAMICIDIN

By KIYOSHI OKUDA*, CHIN-SHIN LIN and PROF. THEODORE WINNICK

Department of Biochemistry and Biophysics, University of Hawaii, Honolulu

It is more than twenty years since Hotchkiss and Dubos[1] isolated the antibiotic substance tyrothrycin from an organism identified as *Bacillus brevis* and fractionated this material with organic solvents into gramicidin and tyrocidine. Later, Craig *et al.*[2] demonstrated by the countercurrent method that both of these peptide fractions were in turn heterogeneous. Tyrocidine *A* has the structure[3]:

$$\begin{tikzcd}
\text{L-valine} \arrow[r] & \text{L-ornithine} \arrow[r] & \text{L-leucine} \arrow[r] & \text{D-phenylalanine} \arrow[r] & \text{L-proline} \arrow[d] \\
\text{L-tyrosine} \arrow[u] & \text{L-glutamine} \arrow[l, "\gamma"'] & \text{L-asparagine} \arrow[l, "\beta"'] & \text{D-phenylalanine} \arrow[l] & \text{L-phenylalanine} \arrow[l]
\end{tikzcd}$$

In tyrocidine *B*, the L-phenylalanyl is replaced by an L-tryptophanyl residue.

The exact composition and amino-acid-sequence has not been determined for the gramicidins. The major *A* component contains glycine, L-alanine, L- and D-valine, D-leucine, L-tryptophan and ethanolamine. Gramicidins *B* and *C* differ from *A* in containing L-phenylalanine and L-tyrosine, respectively, in place of one or more tryptophans[2].

It is of interest that gramicidin *S*, produced by a special strain of *B. brevis*[4], has the identical pentapeptide sequence from L-valine to L-proline as does tyrocidine *A* (but repeated twice).

The need to investigate further the chemistry of the gramicidins arose in connexion with present investigations[5] on the biosynthesis of polypeptides in the Dubos strain of *B. brevis*. Two gramicidin preparations have been subjected to quantitative amino-acid analysis with the Beckman/Spinco model 120 automatic analyser: a commercial sample kindly supplied by the Wallerstein Laboratories, and gramicidin from a culture of *B. brevis* (A.T.C.C. 8185, Dubos strain *BG*). This latter gramicidin was isolated from tyrothrycin by chromatography on a charcoal–cellulose powder column[5], and then purified further by passage through a column of silica gel[6]. The two polypeptide preparations had identical ultra-violet absorption spectra[5]. Samples were hydrolysed with glacial acetic acid/concentrated hydrochloric acid (1:1 by vol.) at 110°–112° in evacuated tubes for specified times. After removal of acid, samples corresponding to 1.2 mg of original material were analysed with both the short and long 'Dowex' resin columns[7].

---

* On leave from the Department of Biochemistry, Osaka City University Medical School, Osaka, Japan.

The results are summarized in Table 1. Tryptophan was progressively destroyed during the acid hydrolysis. However, a reliable value for this amino-acid, based on an analysis by Fraenkel-Conrat *et al.*[8] of an alkaline hydrolysate of Wallerstein gramicidin, is included for purposes of calculation and discussion.

Table 1. Amino-acid Analysis of Gramicidin

Amino-acid	Commercial gramicidin: Amino-acid/mg peptide (μmoles) 24-h hydrolysis	Commercial gramicidin: Amino-acid/mg peptide (μmoles) 48-h hydrolysis	Commercial gramicidin: No. of residues relative to glycine*	Gramicidin 8185 48-h hydrolysis: Amino-acid/mg peptide (μmoles)	Gramicidin 8185 48-h hydrolysis: Residues relative to glycine
Glycine	0.515	0.530	1.00	0.479	1.00
Alanine	1.030	1.042	1.985	0.927	1.935
Valine	2.010	2.102	3.93	1.837	3.835

Tyrosine	0.118	0.127	0.235	0.075	0.156
Tryptophan	1.865		3.62		
Ethanolamine	0.27	†	0.52	0.30	0.62

* Average of 24- and 48-h values.

† Could not be calculated, due to excessive merging with the ammonia peak.

It may be seen that there was good agreement between the 24- and 48-h values for the commercial gramicidin, proving that the hydrolysis was complete. Very similar results were obtained with the gramicidin derived from the A.T.C.C. 8185 culture, but these values may be less accurate in an absolute sense, since the determination of the initial quantity of peptide was based on an indirect spectrophotometric measurement, rather than on weighing. If the μmoles of each amino-acid are multiplied by the residue weight (minus water), the total μg (including ethanolamine) accounted for, per mg polypeptide, is 932 for the commercial gramicidin. This recovery is fair in view of unavoidable losses due to handling and to partial destruction of ethanolamine.

In analyses utilizing the short 15-cm column, ethanolamine preceded ammonia as a discrete peak with the 24-h hydrolysate. In the 48-h samples, the size of the ammonia peak was increased, and the latter was not well resolved from the amino-alcohol. Hence accurate calculations were not possible. It should be mentioned that, in addition to traces of ornithine, variable quantities of other ninhydrin-positive substances appeared in the chromatograms with the 15 cm column. These could not be assigned to any known amino-acids, and they probably represent artefacts resulting from the destruction of tryptophan (and possibly from ethanolamine). With the 150 cm column, aspartic acid, glutamic acid and proline (components of tyrocidines) were detected in only very small, or in negligible, concentrations.

James and Synge[9] have devoted considerable effort to the determination of the ethanolamine content of gramicidin. We have observed that the amino-alcohol labelled with carbon-14 is quite stable to prolonged heating in acetic-hydrochloric acid, in the presence of gramicidin. However, the ethanolamine which occurs bound to gramicidin (possibly through the indole nucleus of tryptophan) is destroyed to a considerable extent during acid hydrolysis[9]. The 24- and 48-h values for ethanolamine in Table 1 are not quantitative chiefly for this reason. The average of the two reported determinations corresponds to an ethanolamine/glycine ratio of 0.57. The corrected data of James and Synge, taken in conjunction with various direct measurements on the gramicidin molecule, gave a value of approximately 0.60 μmole ethanolamine per mg polypeptide[9]. This represents close to one amino-alcohol per glycine and is very probably correct.

On the basis of the best analytical values available at the time, Synge[10] proposed that (mixed) gramicidin contained 2 glycyl, 3 alanyl, 5 valyl, 6 leucyl, 6 tryptophanyl and 2 ethanolamine residues. From the quantitative analyses in Table 1, it may be seen that glycine, alanine and valine actually occur in a 1:2:4 ratio in gramicidin. The leucyl plus isoleucyl residues total close to 4. Likewise, the sum of tryptophanyl, phenylalanyl, and tyrosyl groups is near 4. Since the chief component, gramicidin *A*, appears to contain no tyrosine or phenylalanine[2], its minimum molecular composition is 1 glycine, 2 alanines, 4 valines, 4 leucines, 4 tryptophans, and 1 ethanolamine. However, there are reasons for proposing that the gramicidin molecule has twice this number of residues.

(1) Since L-valyl glycine and D-leucyl glycine have both been isolated from a partial hydrolysate of gramicidin[11], the polypeptide must contain at least two glycine residues.

(2) The calculated molecular weight for gramicidin *A*, assuming 30 amino-acid residues plus 2 ethanolamines, is 3,725. This value is in good agreement with the figure of 3,800, derived from crystallographic data[12].

(3) Apart from æsthetic considerations, an even number of amino-acid residues seems likely, in view of similar situations in the cases of gramicidin *S* and tyrocidines *A* and *B*.

The presence of a small proportion of isoleucine in mixed gramicidin preparations is noteworthy and merits further study. It is possible to estimate the proportions of gramicidins *A*, *B* and *C* in the commercial preparation, from the data for phenylalanine, tyrosine, and tryptophan, by making certain assumptions.

If it is postulated that gramicidin *B* contains 3 phenylalanines plus 5 tryptophans, and gramicidin *C* 3 tyrosines plus 5 tryptophans, the μmole of *B* is 0.036/3 or 0.012 and the μmole of *C*, 0.122/3 or 0.0407, per mg of mixed gramicidin. Subtracting the tryptophan in *B* (0.036 × 5/3) and in *C* (0.122 × 5/3) from the total μmole, 1.865, the remaining tryptophan assignable to gramicidin *A* becomes 1.60. This last figure is equivalent to 0.20 μmole of *A*. On this basis, the percentages of *A*, *B* and *C* are approximately 79, 5 and 16. If these values are compared with those calculated from Craig's counter-current separation data ($A:B:C = 78:16:6$)[2], in both cases the *A* component represents almost 80 per cent of the total gramicidin. However, the proportions of *B* and *C* are reversed in the two situations. The explanation for this discrepancy is not clear at present. It will be noted that gramicidin 8185 has a higher phenylalanine and a lower tyrosine content than the Wallerstein sample, so that its content of gramicidins *B* and *C* would agree more closely with the counter-current ratios. Studies are in progress in our laboratory to determine the amino-acid sequences and exact structures of the gramicidins.

In summary, the Dubos strain of *B. brevis* contains two remarkable and contrasting groups of polypeptides, the basic tyrocidines with 10 amino-acid residues and molecular weights of about 1,300, and the neutral gramicidins with three-fold larger molecules. It will be of much interest to elucidate the mechanisms of biogenesis of these substances, and to compare the pathways with those of other classes of peptides and of proteins.

We thank Prof. K. T. Yasunobu for lending us his analytical equipment.

This investigation was supported by research grants from the U.S. National Science Foundation and the U.S. Public Health Service.

ORIGIN OF EXINE

By Prof. J. HESLOP-HARRISON

Department of Botany, University of Birmingham

It has been known for practically a century that during the early development of pollen, refractive particles accumulate on the inner and to some extent also on the side faces of the tapetal cells[1]. These particles, which may take the form of flattened plaques, cups or hollow spheroids, show all the staining properties of exine and respond in the same manner to several microchemical tests[2,3], from which it seems probable that they are chemically the same. Their formation has been interpreted either as revealing a homology between tapetal cells and the microspores[4] or as giving evidence of the role of the tapetum in contributing to the development of the pollen exine[5].

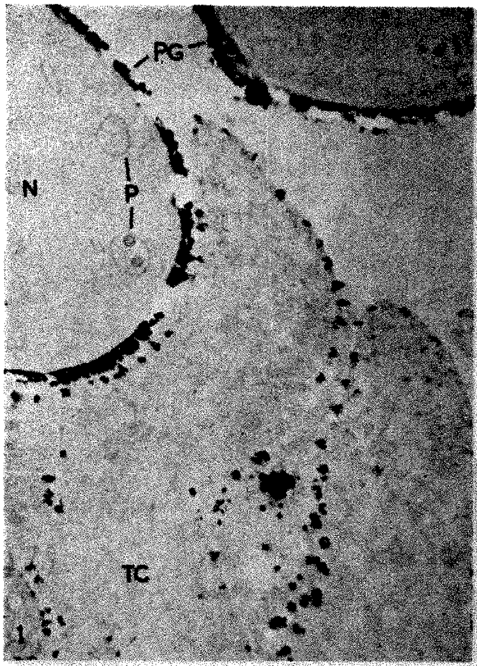
Recently, with the beginning of electron microscopic studies of pollen and tapetum, these particles have been redescribed in various flowering plants and gymnosperms by Rowley, Mühlethaler and Frey-Wyssling[6] and Chambers and Godwin[7]. Their similarity in density in the electron beam following osmic fixation and their resistance to acetolysis provide additional evidence of chemical identity with the exine material, and the affinity is further emphasized by the correspondence in surface features and fine structure.

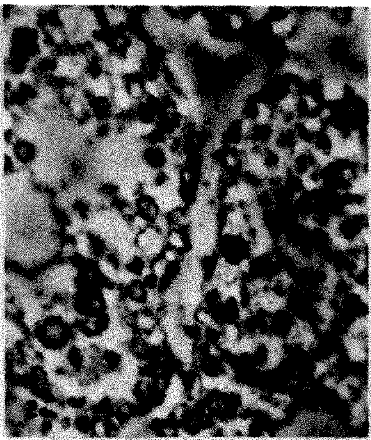
In the course of a study of tapetal function in normal and experimentally induced male sterile plants of *Silene pendula* and *Cannabis sativa* (hemp), the origin of the tapetal particles has been traced. Material for electron microscopic examination was fixed in 1 per cent unbuffered osmic acid for 1½ h at 2°–3° C, or in 2 per cent potassium permanganate for 1–2 h at room temperature, followed by alcoholic dehydration and embedding in 'Araldite'. Sections were cut on a Cambridge Instruments Huxley pattern ultramicrotome, and the observations were made with Metropolitan Vickers *EM*6 and Akashi microscopes.

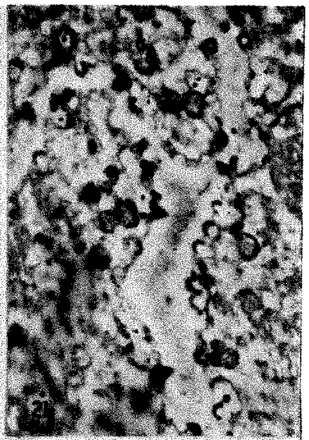
The particles and their association with the exine of the young microspores are strikingly illustrated with short period permanganate fixation in hemp (Fig. 1). With this fixation the tapetal organelles give little contrast, but the particles show high electron density. They most commonly reveal an O- or U-shape, suggesting that they are in fact shallow cups presenting one or other of these appearances according to the angle of sectioning. At the outer surface of the tapetal cells they show a regular orientation with the open end of the cup facing inwards. In some cases direct continuity between the outer surface of the cup and the exine of adjacent microspores may be seen.

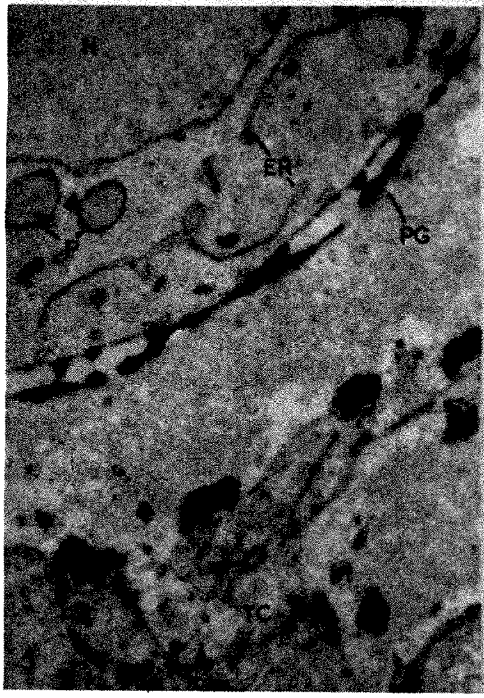
The significance of the cup shape becomes evident when the organelles near the plasmalemma of the tapetal cells are examined after osmic fixation (Fig. 2*a*, *b*). Just within the protoplast spherical or ellipsoidal bodies are present which show a cap-like accumulation of electron-dense material around one pole. These bodies have the dimensions of mitochondria, and there is occasionally sufficient evidence of cristæ to suggest that this is what they are. At the surface of the protoplast the caps of electron dense material appear in regular rows, while within the cell the membranes of the other pole are seen in various stages of dissolution.

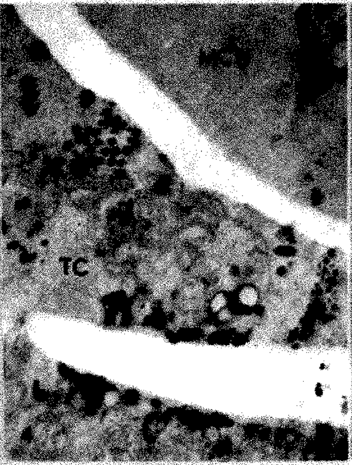
In *Silene pendula* the granules on the outer faces of the tapetal cells are larger, and can in fact be resolved with the optical microscope. With permanganate fixation they possess great electron density, and reveal a distinctive internal structure consisting of spherical cavities (Fig. 3). These large granules seemingly arise through the aggregation of smaller ones, since they are preceded in the early development of the tapetum by groups of electron-dense particles, sometimes with an annular appearance, ranging up to 600 Å in diameter (Fig. 4). Moreover, in the older tapetum a sequence of sizes can be traced in the interstices between the anticlinal faces of the tapetal cells from the large granules lying adjacent to the theca to particles nearer the anther wall of the size of those present on the young tapetum (Fig. 5). Again, material of the same electron density can be detected within the protoplast, contained in membrane-bounded organelles. While in hemp the material forms caps at the poles, in *Silene* it is in the form of discrete particles (Fig. 6). The presence of the particles obscures structure to some extent, but once more it seems probable that the organelles are mitochondria. An origin in plastids can be ruled out, since these are readily distinguishable in the tapetum of *Silene* at this stage, frequently characterized by their amœboid form.

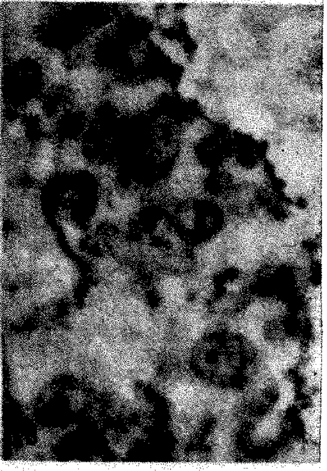


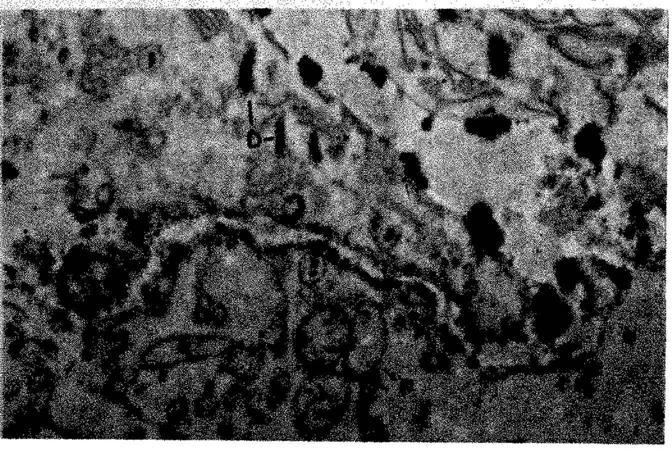












Figs. 1 and 2. *Cannabis sativa*

Fig. 1. Tapetal cells (*TC*) with adjacent pollen grains (*PG*). Conspicuous plastids (*P*), some with starch grains, are present in the pollen. *N*, nucleus. The pollen wall has been torn in a few places during sectioning. (× *c.* 2,000; permanganate fixation)

Figs. 2*a* and *b*. Two parts of a cleft between adjacent tapetal cells, showing the cap-forming organelles within the protoplast, caps aligned at the protoplast surface, and residual membranes. (*a*, *c.* 7,300; *b*, *c.* 6,800; osmic fixation)

Figs. 3–6. *Silene pendula*; all permanganate fixation

Fig. 3. Tapetal cell (*TC*) with adjacent pollen grain (*PG*). *P*, plastids; *ER*, endoplasmic reticulum; *N*, nucleus. (× *c.* 6,000)

Fig. 4. Tapetal cell (*TC*), partly in surface view, with adjacent microspore tetrad still invested in the mother cell wall (*MCW*). Particles in different stages of aggregation are visible. The white band at the base of the picture is a wall between neighbouring tapetal cells, in the course of dissolution. (× *c.* 9,000)

Fig. 5. Cleft between adjacent tapetal cells beginning near the theca (top centre) and extending inwards towards the anther wall. The organelles, presumed to be mitochondria, containing the dense particles may be seen throughout the picture, and large numbers of the particles are present adjoining the cleft, where residual membranes may be seen. *P*, plastids; *D*, dictyosomes. (× *c.* 4,500)

Fig. 6. The particle-containing organelles near the protoplast surface at higher magnification. (× *c.* 13,000)

Whereas in hemp the electron-dense material is presented at the plasmalemma as a cup, base first, in *Silene* the particles seem to be discharged at the cell surface in a random manner by the sacrifice of the organelles within which they are contained, aggregation following later in some as yet obscure way.

The question arises whether this mechanism in the tapetum is that through which all the exine material of the sporogenous mass of the anther is synthesized. On the whole it seems probable that it is. In *Silene*, the formation of exine material in the tapetum begins during the early stages of meiosis, and appreciable accumulations are present at the tetrad stage, when the microspores are invested in the mother cell wall and are without exine. There are no interstitial cells in the anthers of the two genera examined, and a careful search has revealed no evidence of the formation of exine material in the organelles of the microspores—indeed, as will be reported more fully elsewhere, there is every reason to believe that the exine material is applied from without. By what mechanism it is transported from the tapetal cells to the young spores remains a mystery, since continuities such as those seen in Fig. 1 can obviously be present only with peripheral grains. It is noteworthy, however, that exine can sometimes be seen to develop first on the side of pollen grains lying towards the tapetum, a fact which has been taken as evidence of the role of the latter tissue in the synthesis of exine material[5].

Finally, it is significant that exine formation is not necessarily severely reduced in sterile pollen of *Silene pendula*. Notwithstanding an early degeneration of the protoplast after the break-up of the tetrads in anthers rendered sterile by abnormal photoperiod régimes[8,9], exine is formed and applied to the spore walls. The tapetum, which does not generate the elaborate mass of endoplasmic reticulum found in fertile anthers, nevertheless produces the superficial granules. In a comparison of normal and male-sterile maize, Edwardson[10] has reported the presence in tapetal cells of particles of the type described here, and has suggested that there may be consistent differences in the sizes of the particles and the persistence of their enveloping membranes in fertile and sterile anthers. If the role of the particles is as suggested here, it is difficult to suppose that they have themselves anything directly to do with pollen fertility and sterility.

I thank Mrs. P. G. Roberts for assistance, the Department of Physical Metallurgy, University of Birmingham, for the use of the Metrovick microscope, and Prof. O. Lowenstein for making available the Akashi microscope by permission of the Wellcome Foundation, the owners of the instrument.

REGULATION OF UNESTERIFIED FATTY ACIDS OF THE PLASMA DURING THE ONSET OF STARVATION

By Dr. P. A. MAYES

Royal Veterinary College, London, N.W.1

THE reciprocal relationship between glucose utilization and the release of unesterified fatty acids from adipose tissue is considered to be of crucial importance in caloric homeostasis[1]. Recent work has demonstrated that the rate of production of unesterified fatty acids controls the concentration of such acids in the plasma, which in turn determines their rate of uptake by the tissues[2]. Generally, the concentration of metabolic substrates in the blood is the main factor which determines their rate of utilization. This does not necessarily follow for glucose since other factors, including insulin, have a marked effect on its utilization. Nevertheless, a reciprocal relationship exists between the levels of plasma glucose and of unesterified fatty acids over a wide range of conditions which involve progressive depletion of available body carbohydrate and the need to draw increasingly on fat as a source of calories[1]. During an investigation in this laboratory of the metabolic factors involved in the transition of rats from the fed to the fasting condition, a nearly threefold increase in plasma unesterified fatty acids occurred before there was any significant fall in the blood glucose concentration.

Female albino rats (av. body-wt. 197 gm.) were divided into two groups, a control group provided with the normal stock diet and a group from which food was withdrawn at 10 a.m., designated the 'fasting' group. At intervals of 2 hr., animals from each group were killed by decapitation and blood was obtained for the estimation of plasma unesterified fatty acids[3] and blood glucose[4]. Experimental details of the method used for estimating the liver glycogen content have been described previously[5]. Before the experiment, the rats were handled frequently and the length of daylight, which influences the feeding pattern, was kept constant (6 a.m.–8 p.m.). The environmental temperature was 21° C.

The results obtained from the controls are summarized in Fig. 1(*A*). These show the variations in blood glucose, plasma unesterified fatty acids and liver glycogen which occurred in normal fed rats between 10 a.m. and 6 p.m. The small fluctuations in blood glucose and plasma unesterified fatty acids varied in a reciprocal manner. In the fasting rats (Fig. 1*B*) there was a very regular increase in circulating unesterified fatty acids from 10 a.m. onwards. The rise from 10 a.m. to 2 p.m. was highly significant ($P < 0{\cdot}001$) and was of particular interest as there was no reciprocal change in blood glucose concentration during this period ($P > 0{\cdot}2$). By 4 p.m., however, the glucose-level had fallen significantly

($P < 0{\cdot}001$) and continued to fall until the end of the experiment.

The relationship between the blood glucose and the unesterified fatty acids was examined more closely by plotting the individual results (Fig. 2) and subjecting them to linear regression analysis. A single regression line (A) could be fitted to the data obtained from the fed rats from 10 a.m. to 6 p.m. (P 0·01–0·05) and a similar line (B) could be fitted to the data obtained from the fasting rats from 2 p.m. to 10 p.m. ($P < 0{\cdot}001$). Although the slopes of the lines A and B were not significantly different (P 0·05–0·2), they could not be considered identical because of their distance apart ($P < 0{\cdot}001$). This distance represents the transition from the fed to the fasting condition taking place from 10 a.m. to 2 p.m. (Fig. 1A). During this time the level of blood glucose remained approximately constant, and the liver glycogen content fell by the same amount, in both the fed and the fasting animals. The lack of a definite rise of unesterified fatty acids in the fed animals could be ascribed to the effect of extra glucose absorbed from the gut, but this does not explain why, for a given concentration of blood glucose, the output of unesterified fatty acids is approximately half as much in the fed as in the fasting, post-absorptive animals (Fig. 2). An extra secretion of insulin in the fed animals would increase glucose utilization and could account for this effect. However, if an increase in insulin secretion is caused by hyperglycæmia it is difficult to see what factor would increase insulin secretion significantly from 10 a.m. to 2 p.m. in the fed rats as their blood sugar-levels during this period are virtually identical with those of the fasting rats. At this time the fed rats only occasionally nibble at their food and are forced to draw on their glycogen stores.

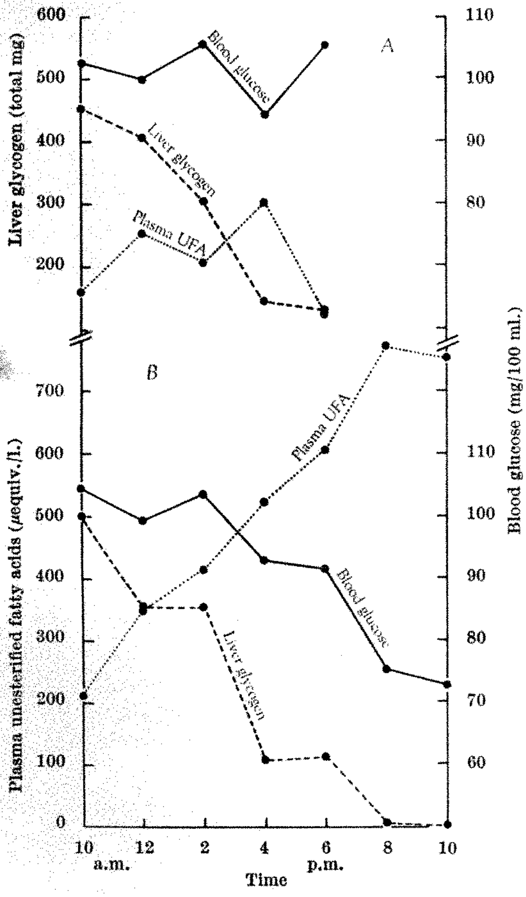

Fig. 1. Changes in blood glucose, liver glycogen and plasma unesterified fatty acid levels; (A) in rats with access to their normal stock diet; and (B) in rats deprived of food from 10 a.m. In (A) each point is the mean from four animals; in (B) each point is the mean from six animals except at 10 a.m., which is the mean from five

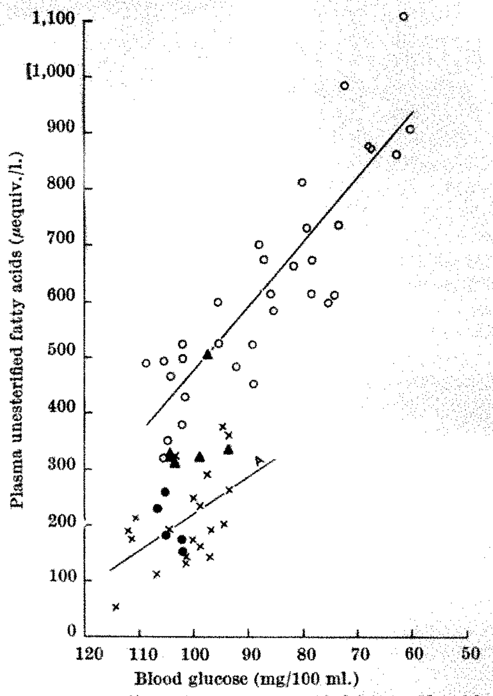

Fig. 2. Regression lines of plasma unesterified fatty acid on blood glucose concentration in (A) fed and (B) fasting rats (2 p.m. to 10 p.m.). ×, fed rats (10 a.m. to 6 p.m.); ●, fasting rats (10 a.m.); ▲, fasting rats (12 noon); ○, fasting rats (2 p.m. to 10 p.m.)

It has been suggested that glucose inhibits the output of unesterified fatty acids from the depots by virtue of it being a ready source of calories[6]. If this is so then other utilizable, calorigenic substrates should act similarly. Amino-acids[6], fat[7] and even acetate in sheep[8] will suppress plasma unesterified fatty acids, and, furthermore, human subjects on carbohydrate-poor diets still show a fall in plasma unesterified fatty acids after meals[9]. It follows that in the present work, the apparently greater effect of glucose in suppressing formation of unesterified fatty acids in the fed animals may at least, in part, be due to the additional effect of the other calorigenic constituents of the diet.

Interpreted in this way, the results are compatible with the hypothesis that the regulation of the output of unesterified fatty acids from the fat depots varies inversely with the total rate of utilization of all calorigenic substrates.

METABOLICALLY LINKED CHANGES IN FLUORESCENCE EMISSION SPECTRA OF CORTEX OF RAT BRAIN, KIDNEY AND ADRENAL GLAND

By PROF. BRITTON CHANCE, VICTOR LEGALLAIS and BRIGITTE SCHOENER
Johnson Research Foundation, University of Pennsylvania

IN a concurrent paper we have described the development of a microfluorometer suitable for measuring changes in the oxidation-reduction level of the intracellular pyridine nucleotide component in tissues of the rat[1,2].

In the previous method the fluorometer was designed for measuring emission over a fixed wavelength region. Identification of the fluorescing component was based on the assumption of identical fluorescence emission properties in both *in vivo* and the excised tissue. The excised tissues were studied by a specially designed spectrofluorometer which was sensitive to their fluorescence changes. Since it is highly desirable to identify the nature of the fluorescing changes directly, *in vivo*, the microfluorometer apparatus has been modified in order to incorporate a continuous interference filter of a 30μ spectral interval. This interval is shown to be sufficiently narrow for measurement of the fluorescence emission spectrum of mitochondrial pyridine nucleotide and sufficiently broad to allow an adequate measurement accuracy. This article reports fluorescence emission spectra of kidney, brain, and adrenal cortex of anæsthetized rats and shows how the intensity of these fluorescence spectra changes in different metabolic states, such as aerobiosis and anoxia.

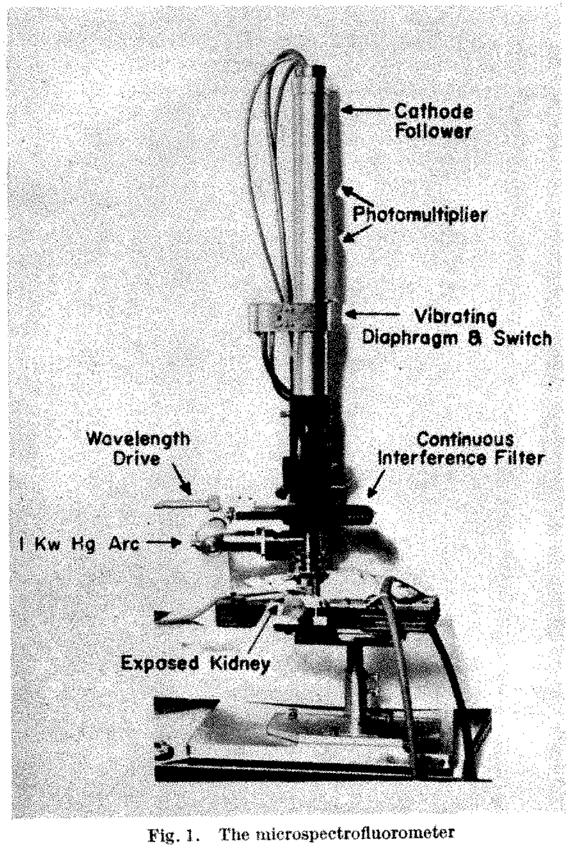

Fig. 1. The microspectrofluorometer

Fig. 1 shows the microspectrofluorometer. In appearance the instrument is identical to that described before[2], except that a continuous interference filter (Schott) is seen as the rectangular object placed near the back aperture of the objective. A flexible shaft connects this filter to the drive of a chart recorder. A counter is used for resetting the wave-length to pre-calibrated points. Since the interference filter gives an approximately linear relationship between displacement and wave-length, the direct gearing between the chart recorder gives the wave-length scale as 10 mμ per division indicated in the figures of this paper. In addition to the interference filter, a Wratten type 2*C* filter is also placed in the back aperture of the objective. The wave-length-range of the interference filter is 400–700 mμ, and the specification on its spectra interval is 30–40 mμ. In order, however, to compensate somewhat for the loss of light intensity, the measuring aperture has been increased from 15–30μ. Other features of the apparatus are briefly summarized: the 1,000-watt high-pressure mercury arc excites the fluorescence of the specimen at 366 mμ by means of an 'Eppendorf' primary filter. Fluorescence excitation and emission pass through the Leitz Ultrapak objective (× 11) and a × 3 ocular. Olson[3] and Loeser and West[4] have described rapid scanning spectrofluorometers which could be suitably modified for these studies.

Fig. 2 indicates the performance of this microspectrofluorometer as compared with that of a macrospectrofluorometer operating with a 10 mμ spectral interval. Two substances are studied, 4-β-methyl umbelliferone (7-hydroxy-coumarin) and a suspension of pigeon heart mitochondria. The half-widths of the emission spectra for pigeon heart mitochondria measured in the two instruments are both 77 mμ. The half-width for umbelliferone is 56 mμ in the macro-instrument and 58 mμ in the micro-instrument. Since the component of tissues in addition to reduced pyridine nucleotide, which might be expected to be observed, is that of flavin, and since the emission band of this substance is even broader than that of reduced pyridine nucleotide, the microspectrofluorometer is considered adequate for the *in vivo* experiments.

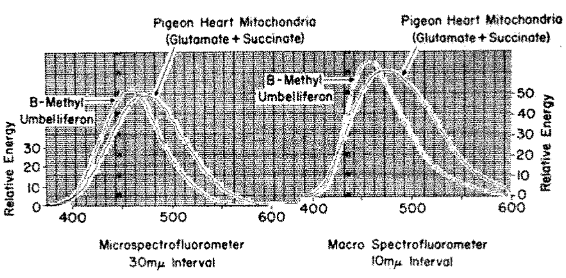

Fig. 2. A comparison of the performance of the microspectrofluorometer with that of an instrument using a grating monochromator (250 mm. focus) set at a 10 mμ interval. The pigeon heart mitochondria were treated with glutamate and succinate in order to give maximal reduction of pyridine nucleotide in the aerobic state

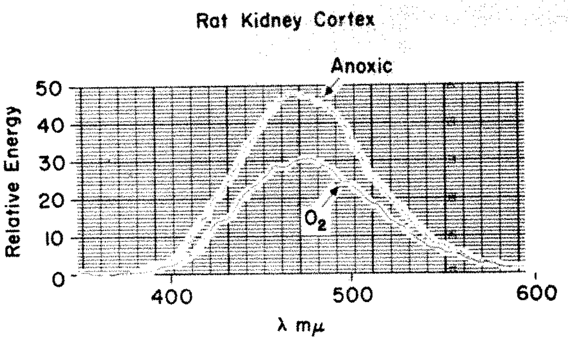

Fig. 3. Fluorescence emission spectra of rat kidney cortex with rat breathing oxygen and rat anoxic

The emission spectra are uncorrected for the energy sensitivity of the cæsium–antimony photosurface. Thus, the peaks of these emission spectra for mitochondrial reduced pyridine nucleotide are at 473 mμ instead of 443 mμ[2]. However, our attention is directed in these studies to the similarity of the emission spectra of isolated mitochondria (Fig. 2) and the intact tissue (see the following figures).

Rat kidney cortex. With the microscope focused on the kidney cortex of the anæsthetized rat, the field appears pale blue and the small blood vessels are seen in dark outlines against the uniform blue background. The kidney is held in a small cup, which reduces considerably motion due to respiratory movements[2]. The microscope is focused on an area of bright fluorescence containing a minimum of blood vessels.

Two types of recording are used, one a time recorder and the other a wave-length recorder. With the monochromator set at 470 mμ, a time recording of several minutes is taken in order to ensure that a stable base-line is obtained with the animal breathing oxygen. Then a spectrum is run through and appears as the lower trace of Fig. 3 (oxygen). The peak of the emission spectrum lies near 475 mμ, and the shape of the emission spectrum suggests that only one component is involved. The inspired gas is changed to nitrogen, and when the time recorder indicates that the fluorescence has reached a plateau (approximately 30 sec. after cessation of breathing)[2], the second spectrum is run (this requires approximately a minute). This time interval is sufficiently short that the animal may be resuscitated by the use of a few manual ventilations following a change of the inspired gas to 100 per cent oxygen. When breathing is resumed, a third spectrum may be run in order to bracket the anoxic spectrum with two aerobic ones (Fig. 4). The fluorescence intensity obtained in anoxia is 60 per cent higher than in the aerobic condition. The peak of the emission spectrum obtained in anoxia is at approximately 470 mμ, and the distribution of energy is maximal at a slightly shorter wave-length than when the animal breathes oxygen. This suggests a greater contribution of bound reduced pyridine nucleotide, presumably that of the mitochondria. The absence of prominent emission bands in the region of 540 mμ indicates that no measurable amount of free flavin is present in the areas under observation in either aerobic or anoxic states.

Adrenal gland. Fig. 4 represents a similar study of exposed cortex of the adrenal gland. The animal was hypophysectomized two days previously and has been treated with 400 milli-units of adrenocorticotrophic hormone. The fluorescence changes described elsewhere[5] have already occurred. With the animal breathing oxygen, the peak of the emission band lies at approximately 475 mμ. If the inspired oxygen concentration is dropped to zero, the emission spectrum rises to a peak nearly identical in wavelength and about 40 per cent higher in intensity. This may be compared with the 60 per cent increase in the case of the rat kidney. If the animal is allowed to breathe oxygen again, the intensity of the emission spectrum diminishes, and the dashed curve is obtained. Here again, the graph suggests the emission spectrum of mitochondrial reduced pyridine nucleotide. The small shift in the anoxic spectrum observed in the kidney is not seen, however, in the adrenal gland.

Brain cortex. Fig. 5 indicates a similar experiment with the microspectrophotometer focused on a small area of the brain near the preoccipital cortex. A trace labelled aerobic is obtained with the animal breathing 20 per cent oxygen and 80 per cent nitrous oxide. The emission spectrum is seen to have a broad maximum at 479 mμ. About a minute after changing the inspired gas to 100 per cent nitrous oxide, the fluorescence increases, and a more distinct peak is now observed at approximately the same wave-length. The similarity of this peak to reduced pyridine nucleotide fluorescence of isolated mitochondria is again to be noted.

In two of the three tissues examined, kidney and brain cortex, emission spectra for excised tissues have been obtained in the perfused and unperfused state and show peaks on a relative energy basis, within several mμ of the wave-lengths observed here (473 mμ). It is of considerable importance to confirm that no artefact has occurred in the use of excised tissues and that the material *in situ* in the anæsthetized animal gives, as a major component of its fluorescence, that which we can attribute to bound reduced pyridine nucleotide. These data show fluorescence increases in the transition from aerobiosis to anoxia in the excised tissues, in the same proportion to those observed *in vivo*. Experiments on excised slices of the cat brain cortex identify increased absorption at 340 mμ to occur in the transition from aerobiosis to anoxia[6].

As in the case of the excised tissues, this type of measurement does not clearly distinguish between the mitochondrial and the cytoplasmic material.

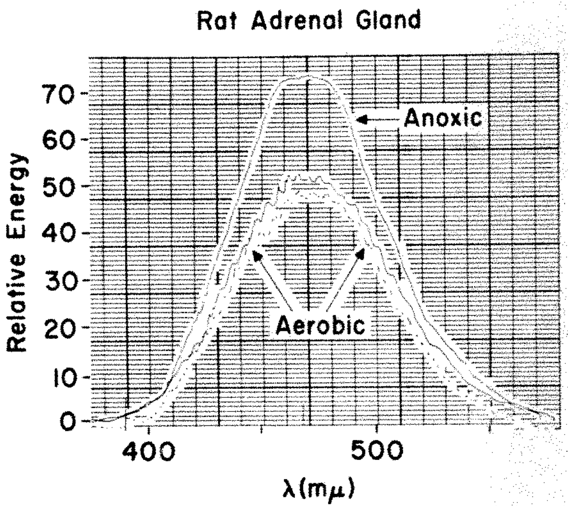

Fig. 4. Fluorescence emission spectra of rat adrenal cortex with rat breathing oxygen and rat anoxic

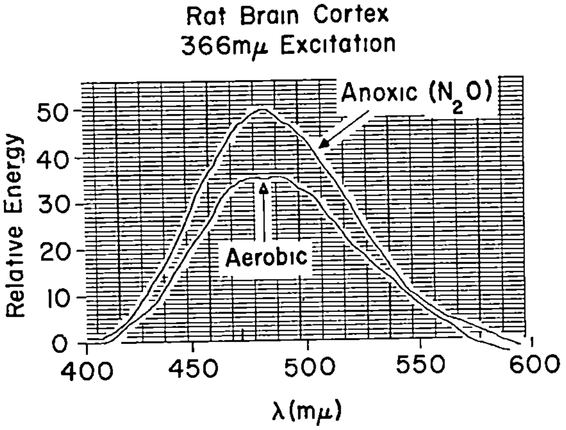

Fig 5 Fluorescence emission spectra of rat brain cortex with rat breathing oxygen and rat anoxic

Experimentation with appropriate inhibitors, such as 'Amytal', however, has already shown that a large part of the change of fluorescence emission occurs in the presence of 'Amytal' and oxygen, suggesting a major contribution to the fluorescence change of the mitochondrial pyridine nucleotide[2]

The positions of the peaks of the emission spectra are sufficiently close to those of the emission spectrum for the reduced pyridine nucleotide component of a suspension of isolated mitochondria (473 mμ) that we identify this material as the major fluorescing component in these spectra

At the present time, insufficient data are available to attach significance to the few millimicrons difference in the position of the peaks of the emission spectra or to the 10–20 per cent difference in the fluorescence increases which occur in this transition from aerobiosis to anoxia in the different organs No doubt further experiments will allow us to attach a greater significance to these quantitative aspects

The lack of evidence for measurable amounts of fluorescent material other than that of reduced pyridine nucleotide is largely a consequence of the preponderance of fluorescence of this material Undoubtedly, in tissues depleted of reduced pyridine nucleotide, other components could be observed The results, however, suggest that with 366 mμ excitation at least, the possibility of measuring intracellular components of these tissues other than reduced pyridine nucleotide is rather small

SODIUM CARBONATE LAVAS FROM OLDOINYO LENGAI, TANGANYIKA

By J B DAWSON

Geological Survey of Tanganyika, Dodoma

OLDOINYO LENGAI is an active volcano lying some ten miles south of Lake Natron in the eastern or Gregory Rift Valley of northern Tanganyika It is a composite cone consisting mainly of ijolitic and nephelinitic pyroclastics which contain ejected blocks of urtite, ijolite, melteigite, jacupirangite, biotite pyroxenite, wollastonitite, calcium carbonatite (sovite), fenite and various types of lava[1] The interbedded silicate lavas vary with decreasing age from phonolite + nephelinite → nephelinite → melanephelinite, giving evidence of a distinct trend of decrease in the silica content of the extruded rocks during the successive eruptions which built the volcano This trend was further emphasized in 1960 when soda-rich carbonate lavas containing virtually no silica were extruded from the vent of the northern crater in the form of both *pahoehoe* and *aa* lava This is the first time that carbonate lava has been recorded from the volcano although earlier workers[2–5] have noted the presence of soda carbonate ash which has been ejected during earlier eruptions It has been suggested[1] that the volcano has resulted from successive intrusions of carbonatite magma into crystalline rocks, each intrusion being less contaminated with sialic material than its predecessor, and the soda ashes and lavas are regarded as approximating in composition to the uncontaminated parental material

Chemical analyses of two of the soda lavas have been made by the Tanganyika Geological Survey Laboratories (Table 1)

Analysts, W K L Thomas, G Luena and P Bowden

* Determined spectrographically by P Bowden Tanganyika Geological Survey reference number *X*/7279/2

The analyses are of a *pahoehoe*-type lava and an *aa*-type lava, and it is noticeable that the lava-types are chemically very similar The most significant feature of the chemistry is the virtual absence of silica and the very small amounts of alumina and iron combined with the very high amounts of alkalis and volatiles In particular the extremely high soda content of almost 30 per cent is indicative of the very unusual nature of these lavas The total volatile content of the *pahoehoe* and *aa* lavas is 49 72 and 47 39 per cent respectively

An exhaustive search of the literature has not revealed any other magmatic rock of a similar composition All recorded examples of intrusive carbonate rocks which are believed to be magmatic[6,7] contain high amounts of lime and/or magnesia while some have a high iron content On the other hand, alkalis are usually present in only small amounts and are contained in silicate minerals such as mica and aegerine, not as alkali carbonate The same general characteristics are also exhibited by the only other known extrusive carbonatite—a calcium-rich carbonatitic lava from western Uganda[8] The carbonate lavas from Oldoinyo Lengai, however, are quite different, having a relatively small lime content and little magnesia and iron, whereas soda and potash together comprise between 36 and 38 per cent with unusually high amounts of fluorine chlorine and sulphur trioxide Moreover, although the strontium content is of the same order as in calcitic or dolomitic carbonatites, the barium, substituting for potassium, is present in greater concentrations in the Oldoinyo Lengai lavas

The presence of this soda-rich carbonate lava as the youngest phase in a nephelinitic–ijolitic volcano, beneath which (according to the evidence of the ejected blocks) is a carbonatite complex, has considerable bearing on certain aspects of the genesis of carbonatite complexes At present the hypotheses for the genesis of carbonatites and their associated complexes may be divided into two groups (*a*) Hypotheses which assume a basic or ultrabasic parent which differentiates to carbonatite This parental magma has been interpreted as pyroxenite[9], peridotite[10], kimberlite[11] and alkali–peridotite or nephelinite[12] (*b*) Hypotheses in which carbonatites are derived from primary carbonatite magmas or carbon dioxide of unknown origin[6,8,13–15].

The Oldoinyo Lengai lavas are the first recorded occurrence of magmatic alkali carbonate In all previous cases the residual carbonatite has been calcitic or dolomitic and this factor has undoubtedly influenced the workers who seek to derive the carbonatite from ultrabasic silicate parents The presence of the alkali carbonate on Oldoinyo Lengai strengthens von Eckermann's contention[6] that alkali carbonate has been instrumental in the formation of the alkaline rocks in carbonatite complexes, although the carbonate magma proposed by von Eckermann in the case of Alno Island is dominantly potassic Moreover, with the proved existence of magmatic alkali carbonate there is now a possible indication of the source of the alkalis required for the fenitization process, a long-outstanding problem, and it may be that variations in the potash and soda content of carbonatite magma account for the differences in the nephelinization processes seen at different centres

Mineralogically, the lavas consist of highly birefringent phenocrysts up to 1 mm long set in a microcrystalline matrix of highly birefringent, hydrated sodium carbonate The phenocrysts are of a new mineral which will be described in a later paper on the petrography of the lavas It is probable that a new name will be given to the lavas in view of their unusual chemistry and mineralogy

I thank Mr. W. K L. Thomas, Mr. G Luena and Dr P Bowden for the analyses Mr J W Pallister and Dr D A Harkin kindly read and discussed the manuscript This communication is published by permission of the Commissioner for Geological Survey, Tanganyika

PROPERTIES OF THE ORGANIC MICROSTRUCTURES OF SOME CARBONACEOUS CHONDRITES

By MICHAEL H. BRIGGS

Department of Geology, Victoria University of Wellington, New Zealand

SEVERAL authors have recently suggested that carbonaceous chondrites contain materials of biological, yet extra-terrestrial origin Conclusive proof of this hypothesis would be of tremendous scientific importance, however, this should not lead to too hasty an acceptance on insufficient experimental evidence To date, two types of evidence have been presented for the presence of biological materials in meteorites First, it has been shown that the distribution of normal and cyclic paraffin hydrocarbons obtained from both the Orgueil and Murray meteorites resembles the distribution of these compounds in crude petroleum, and also in the hydrocarbons of recent marine sediments[1,2] It is argued that this similarity indicates a common origin for the meteorite and terrestrial hydrocarbons As terrestrial petroleum is commonly accepted to be of biological origin, then this indicates a biological origin for the meteorite compounds However, it has been pointed out[3] that while there is some similarity between the hydrocarbon distributions of the meteorites and petroleum, there are differences, and a variety of other objections can be made to drawing a close parallel[3] The argument also rests on the assumed biological origin of crude petroleum While this is certainly a popular hypothesis among Western geologists, an inorganic origin has been supported by several authorities[4] The demonstration of petroleum-like hydrocarbons in meteorites could be used equally as evidence for a non-biological origin for terrestrial petroleum If meteorites are continually adding hydrocarbons to the Earth's surface, petroleum deposits could be accumulations of these compounds

The second argument for the presence of biological materials in meteorites concerns the nature of the 'organized elements' meteorite organic microstructures It has been claimed[4–6] that the microstructures of both the Orgueil and Ivuna meteorites take up biological stains and occur in only a very small number of morphological types There are several difficulties facing the identification of these microstructures First, arguments based on morphology are notoriously subject to personal bias Secondly, contamination of the material under investigation with terrestrial micro-organisms is difficult to eliminate

Examination of the organized elements of the carbonaceous chondrites has now been made independently by several workers and a marked disagreement of opinion has become apparent Thus reports[7,8] from Prof Anders's laboratory at the University of Chicago have stated that attempts to find 'organized elements' resembling those reported by Nagy *et al* [5,6] have largely failed, though terrestrial contaminants and certain mineral and sulphur granules, bearing a close similarity to some of the 'organized elements', were found

It is clear that the nature of the meteorite organic microstructures will be established only by independent examination of samples of the carbonaceous meteorites by more workers in the field In this article a report is presented on the results of an examination of samples of three carbonaceous chondrites

In this laboratory samples of Orgueil, Murray and Mokoia have been examined These meteorites are members respectively of Wiik's classes I, II and III of the carbonaceous chondrites[9] All fragments were carefully examined prior to experimentation to ensure that they were free of any museum markings, fusion crusts and other surface defects To eliminate terrestrial contaminants slides were prepared inside a sterile glove-box The glove-box was thoroughly cleaned and its interior wiped with a dilute solution of phenol The air was gradually removed by suction and replaced with air drawn through glass-wool filters The interior was fitted with an ultra-violet lamp and was irradiated for 2 h prior to the experiments Agar plates were exposed inside the glove-box and, at the completion of the experiments, were removed and incubated No microbial growth was detected on any plate Fractionation of the meteorite samples was conducted also largely within the glove-box using clean, sterile apparatus

As reported by Fitch *et al* [7] a fraction of Orgueil can be obtained that is denser than methylene iodide ($\rho = 3\ 33$) and which on microscopic examination contains numerous approximately spherical particles somewhat resembling the Types I and II 'organized elements' of Claus and Nagy[5] These particles are magnetic, and X-ray diffraction studies indicate the presence of troilite and magnetite Similar fractions were obtained from Murray and Mokoia In the case of these two meteorites the magnetic particles were more irregularly shaped than in Orgueil

Claus and Nagy[5] have reported also the presence of polyhedral 'organized elements' in Orgueil Fitch and Anders[8], however, could find only hexagonal microstructures that they suggested to be goethite pseudomorphs of troilite, together with other hexagonal mineral grains

Examinations of untreated, crushed fragments of the meteorite samples used in this investigation also failed to reveal anything resembling the Type V 'organized elements' of Claus and Nagy[5] However, two distinct types of hexagonal microstructures were detected in Orgueil, though not in Murray or Mokoia The first class were transparent, yellow-brown objects about 12–15μ in diameter They were magnetic Other, rather smaller hexagonal microstructures were opaque and non-magnetic Both classes had a specific gravity greater than 3 33, and were probably troilite grains

In an attempt to verify the report of Nagy *et al* [6] that some of the organized elements can be separated by chloroform extraction, while others can be concentrated with specific gravities between 2 3 and 2 4, the following experiments have been conducted Small samples of each meteorite were treated with chloroform and, after agitation, allowed to stand for two days The chloroform layer was decanted and evaporated in a stream of filtered air The residue was taken up in a small volume of acetone and centrifuged Microscopic examination of the residue revealed no 'organized elements', only a few irregular fragments of a transparent material, some of which were similar to that shown in Fig 2 of a previous paper[10] Similar fragments were obtained from all three meteorites Attempts to concentrate microstructures resembling 'organized elements' from meteorite fragments previously extracted with benzene, by the use of various bromoform–carbon tetrachloride mixtures, were totally unsuccessful However, fragments that had not been previously extracted did yield rounded particles of approximately the specific gravity reported by Nagy *et al* [6] The appearance of these particles, however, was considerably altered on extraction with acetone, then carbon disulphide Consequently, it is probable that they are the sulphur and hydrocarbon droplets previously reported by Fitch *et al* [7].

From the results discussed here it must be concluded that the meteorite samples examined did not contain anything identifiable as the 'organized elements' of Nagy *et al* [5,6] On the other hand, all these meteorites do contain a variety of microstructures which in certain features resemble the 'organized elements' However, it would seem that these microstructures are of several types (*a*) various mineral grains, (*b*) droplets of organic solvent-soluble carbon compounds, possibly associated with elemental sulphur, (*c*) organic solvent-insoluble carbon compounds that perhaps could be high molecular weight hydrocarbon polymers

These conclusions are similar to those of Fitch and Anders[8], who have also presented evidence that some of the 'organized elements' reported by Nagy *et al* [5,6] were contaminating terrestrial pollens and other micro-organisms

At present there is certainly no convincing evidence for the existence of any material within carbonaceous chondrites of extra-terrestrial, biological origin

I thank the following persons for supplying meteorite samples Dr W A Watters of the New Zealand Geological Survey, the Curator of the Wanganui Museum, Dr E P Henderson of the Smithsonian Institute, and Prof Edward Anders of the University of Chicago I also thank Prof R H Clark for advice and assistance with the microscopic examinations

METAMORPHISM OF A LIGNITE

By Dr. J. ROGERS and Dr. R. P. SUGGATE
Geological Survey
AND
J. O. ELPHICK and Miss J. B. ROSS
Dominion Laboratory, New Zealand Department of Scientific and Industrial Research

MANY questions remain to be answered about the influence of the variables, pressure and temperature and time, on the metamorphism of coal. In the field it is difficult to disentangle the effects of pressure and temperature, both of which increase with depth of burial. There are considerable uncertainties in estimating for most coals the maximum depth of burial and the maximum temperature to which they were subjected. Geological and chemical evidence suggests, however, that temperature is of primary importance in determining the degree of metamorphism of coal.

Attempts at the experimental imitation of the coalification process have been reviewed by van Krevelen[1] and Teichmuller[2] and recently extended by van Krevelen *et al.*[3] Although the effects of temperature on the artificial conversion into coal of starting materials like peat, lignite, wood, cellulose, lignin and waxes are now well established, the pressure variable does not appear to have been carefully studied.

As a contribution to the experimental study of the processes of coal metamorphism, the effects of pressure and temperature on an Oligocene lignite from Waimatua, Southland, New Zealand, have been investigated in the high-pressure laboratory, Department of Chemistry, University of Otago. 20–50-gm samples of lignite, crushed to minus ½ in., were heated under defined conditions of pressure and temperature for times ranging from 1 to 63 days. The pressure vessels, or bombs, were similar to those used in hydrothermal investigations of silicates and the pressure medium was water. The products of these experiments were analysed by the Coal Section, Dominion Laboratory.

An analysis of the Waimatua lignite as used in the experiments is given in Table 1, together with the analysis after air-drying at 70 per cent relative humidity at 20° C., and a calculation to the dry, ash-free basis which is used in presenting the experimental results.

A measure of the metamorphism in the relatively low-rank products resulting from the experiments is the calorific value. Fig. 1 shows the influence of temperature on the changes in this property effected in a given time at various water pressures. At 170° C. and above there is an initial rapid change, whereas up to 100° C. the change in calorific value is slow in terms of the times of these experiments.

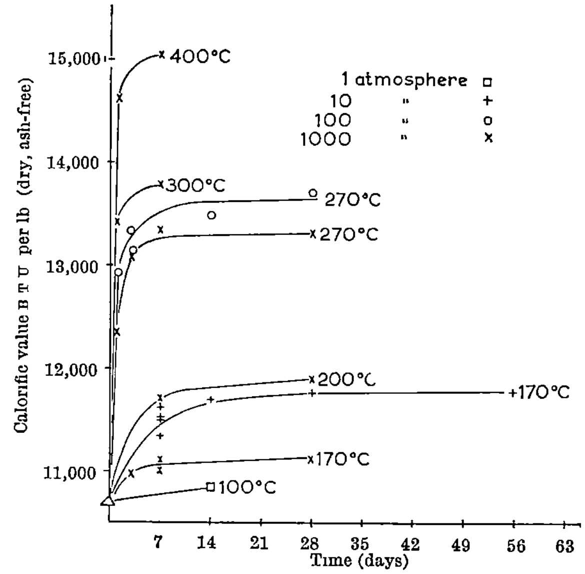

Fig. 1. Changes in calorific value of Waimatua lignite at various temperatures and pressures as a function of time

In numerous experiments at 170° C. there were greater changes in calorific value at 10 atmospheres pressure than at 1,000 atmospheres, as shown in Fig. 1. The equilibrium water vapour pressure at 170° C. is approximately 10 atmospheres. At higher temperatures, greater changes in calorific value were obtained at 100 atmospheres pressure than at 1,000 atmospheres.

Fig. 2 shows that there is a marked point of inflexion at about 170° C. in the calorific value versus temperature

n.f., not found; n.d., not determined

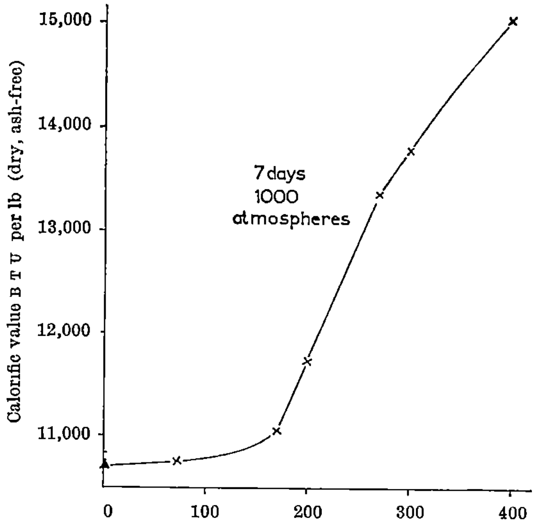

Fig 2 The influence of temperature on the calorific value of the product from heating Waimatua lignite for seven days at 1,000 atmospheres water pressure

curve obtained at 1,000 atmospheres pressure over a period of seven days From the results at 10 atmospheres pressure and seven days, however, the temperature of the point of inflexion is only about 120° C The change in calorific value at a given temperature is less than that shown in Fig. 2 for experimental times shorter than seven days, and more for longer times, but the shape of the curve changes little

The changes in calorific value shown in Figs 1 and 2 are the result of chemical changes in the lignite during the experiments, and the analyses of the gases evolved (Table 2) illustrate, in part, the influence of temperature, pressure and time on the nature and extent of the chemical reactions involved The analyses are expressed as percentages by volume and are calculated to an air-free basis Variable amounts of oxygen and nitrogen, derived from the air in the coal and bomb initially, were always present in the gases

The volume of gas evolved per gram of lignite increases with temperature, especially above 200° C , which is in accord with the greater changes in calorific value above this temperature shown in Figs 1 and 2 At 170° C still smaller amounts of gas were obtained The variables of pressure and time do not influence the volume of gas evolved in the marked and consistent manner of temperature

The composition of the gas evolved also changes with temperature, particularly between 300° C and 400° C where the percentages of carbon dioxide and the saturated hydrocarbons decrease and increase respectively at the same time as the amounts of each gas evolved increase At 300° C and 400° C the percentage of saturated hydrocarbons in the gas increases with time At 270° C the percentage of saturated hydrocarbons produced is greater at 100 atmospheres than at 1,000 atmospheres

Chromatographic analysis of gas from the 400° C samples showed methane to be the major constituent of the saturated hydrocarbon portion, with smaller amounts of ethane, propane, iso- and normal butane, iso- and normal pentane also present At 200° C only methane and ethane were found, whereas at 270° C and 300° C the mixture was methane to the pentanes Small amounts of the unsaturated hydrocarbon, isobutylene, were detected in the chromatograms of some samples, and a trace of propylene in one

In addition to these gases, water is an important product of these experiments and the amount expelled from the lignite increases rapidly above 170° C

In Fig 3, the calorific value and volatile matter of the products of the experiments at the various temperatures and pressures are compared with those of the starting material and with the New Zealand coal band[4]—the path of natural metamorphism of normal-type New Zealand coals It is clear that the products of the experiments above 200° C differ from normal-type New Zealand coals in that their percentage of volatile matter is low In this respect they resemble many coals known to have been metamorphosed by igneous intrusions On the other hand, the progressive decrease of moisture-holding capacity with increase of calorific value is similar to that of normal-type New Zealand coals

A tentative interpretation of the changes of volatile matter and calorific value (expressed on a dry ash-free basis) in Fig 3 is as follows If the lignite is heated to 400° C in less than one day under water pressure, its changing calorific value and volatile matter can be represented, as the temperature increases, by the dotted line bordering the lower volatile edge of the band of experimental results shown in Fig 3 The distance moved along the line is a function of temperature but is also inversely affected by the pressure applied If the lignite sample is held at a constant temperature of 270° C or higher, then the path of metamorphism diverges from the line of rapid heating in a direction more nearly parallel to the natural path The distance along the constant temperature line is a function of time

Although it is not possible to draw any conclusions from these experiments as to the temperature of metamorphism of normal coals, Figs 1 and 2 do indicate that coals will increase only slowly in calorific

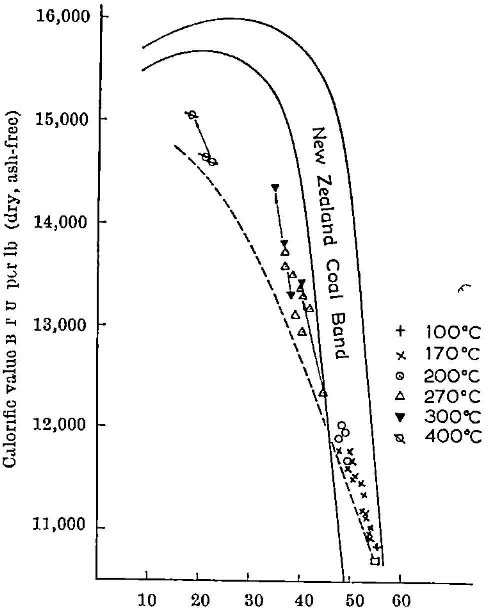

Fig 3 Comparison of the artificial metamorphism of Waimatua lignite at various temperatures with the New Zealand coal band—the path of metamorphism of normal-type New Zealand coals ---, Path of metamorphism during rapid heating, ←, path of metamorphism at constant temperatures

value and rank with temperature until a particular temperature is attained, after which rank increases more rapidly with temperature. The higher the pressure, for $P_{H_2O} = P_{total}$, the higher this threshold temperature will be Although water pressure appears to affect the initial rate of increase of rank the question remains whether the total change over geological periods of time is a function of temperature only

ORIENTATION DEPENDENCE OF STRUCTURE IN PYROLYTIC GRAPHITE

By ROBERT H. BRAGG and CHARLES M. PACKER

Lockheed Missiles and Space Co , Sunnyvale, California

PYROLYTIC graphite is made by the pyrolytic decomposition of hydrocarbons on a mandrel heated to temperatures above 1,500° C X-ray investigations have shown that it consists of an oriented aggregate of turbostratic crystallites having unit cell parameters similar to those of carbon blacks at the onset of graphitization[1] The crystallite layer planes tend to lie parallel to the deposition surface, and heat treatment above 2,000° C produces a general increase in this preferred orientation, in crystallite size, and in layer stacking order. After being heated at temperatures above 3,000° C , the material is almost completely graphitized[2,3] A systematic X-ray investigation of singularly nucleated pyrolytic graphite was conducted in which particular emphasis was given to measurements of preferred orientation and the orientation dependence of the structure of individual crystallites following heat treatments The measurements were made on cylindrical rods of circular cross-section 0 15–0 35 cm. in diameter cut from the central portion of 1 0-cm thick plates of material which had been deposited in the temperature-range 1,850°–2,100° C All specimens were heat treated in an argon atmosphere to temperatures in the range 2,200°–3,000° C for periods up to 1,000 min

The X-ray measurements were made at room temperature with the rods mounted in such a way that it was possible to obtain the diffraction profiles for those crystallites in the rod having layer planes tilted at an angle α away from the original deposition surface The integrated intensity, centre of gravity, and the integral breadth were calculated from these results The centre of gravity of the basal reflexion profiles was used to determine the interlayer spacings, and accurate c-axis lattice parameters were obtained by extrapolation using the estimates from the 0002, 0004, 0006 and 0008 reflexions in a Taylor–Sinclair extrapolation[4]

Because there was no preferred orientation in the deposition plane of the deposited material, the observed integrated intensity for the 0002 reflexions I(α) obtained for a rod rotation of α is proportional to the volume of material in the specimen having (0001) normals oriented in the solid angle dω situated in the angular range α to α + dα relative to the original deposition surface

Typical preferred orientation measurements are shown in Fig 1 where the integrated intensity has been normalized at α = 0 The peak intensities actually ranged from 2,000° for the 1,950° C deposition material to about 8,000° for a specimen heated 25 min. at 3,000° C The linearity of the two upper curves shows that in the deposited material the orientation distribution is Gaussian, that is, has the form

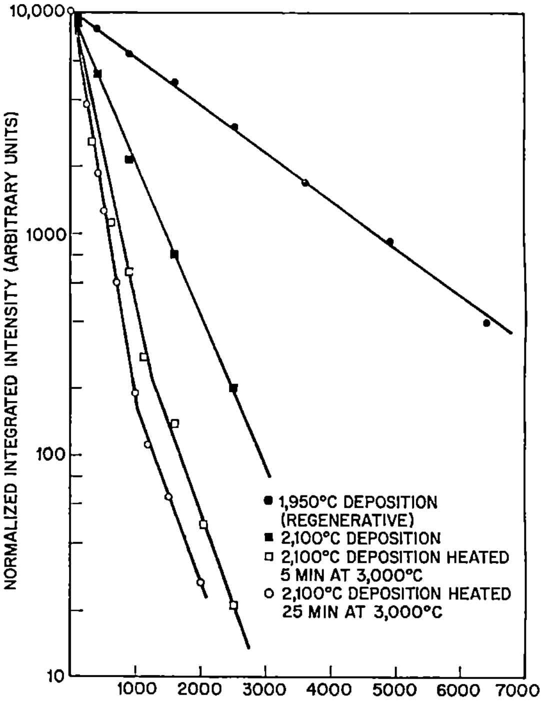

Fig. 1 Preferred orientation in rods of pyrolytic graphite α is the angle of inclination of crystallite layer planes relative to deposition surface in degrees

$$I(\alpha) = I_0 \exp (\alpha^2/2\sigma^2)$$

where σ is the variance of the distribution Increasing the deposition temperature decreases σ, that is, produces a sharper but still Gaussian orientation distribution The lower curves show that the texture is made even sharper by heat treatment at 3,000° C , and it remains approximately Gaussian Similar distributions were noted at all intermediate temperatures, the texture becoming sharper as the temperature rose, and most of the ultimate change at a given temperature occurred within the first hour

The basal texture can be characterized by a mean square crystallite tilt parameter $<\alpha^2>_{AV}$, where

$$<\alpha^2>_{AV} = \int \alpha^2 I(\alpha)\, d\alpha / \int I(\alpha)\, d\alpha$$

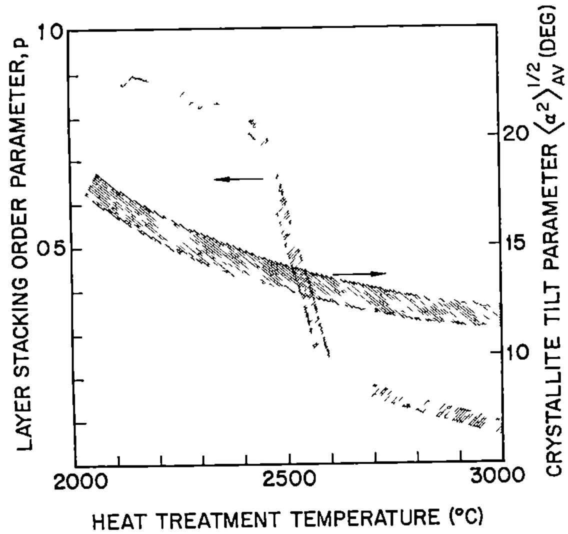

Fig 2 Effect of heat treatment on layer stacking order and crystallite tilt parameter

The layer stacking order attained for a given heat treatment can be characterized by an order parameter, p, which can be deduced from the mean crystallite interlayer spacing[5–7]. Here, p is the proportion of layers within a crystallite which possess the random stacking of turbostratic carbons. Both the crystallite tilt parameter $< \alpha^2 >_{AV}$ and the order parameter p obtained at $\alpha = 0$ are shown in Fig 2. The scatter bands cover the data obtained at 10-, 100- and 1,000-min heat treatments. In contrast to the sharp change in layer stacking order, in the temperature range 2,400°–2,600° C there is no well-defined temperature range in which the crystallite orientation is strongly affected.

The order parameters shown in Fig 2 were obtained at $\alpha = 0$. It was found that with a given specimen the interplanar spacing varies with crystallite orientation angle α. Such a variation could result from residual strains in the massive material, but other studies have shown that heat treatment relieves the strains in pyrolytic graphite[8]. Thus, the observed angular variation in interplanar spacing is due to variations in layer stacking order. Careful measurements show that there is a slight orientation dependence of line width as well, the width being greater for the larger tilt angles.

A typical orientation dependence of layer stacking order is shown in Fig 3 for material heated 100 min at 2,800° C. Similar variations were observed at all temperatures. Fig 3 shows that even in the untreated material, as deposited, the crystallites tilted at large angles from the deposition surface are more disordered than those misoriented by small amounts. While heat treatment sharpens the basal texture and produces a general ordering, it is less effective on the highly misoriented material. In fact, comparison of the two curves in Fig 3 shows that the total range of p is actually increased by heating. The extreme tails of the lower curves of Fig 1 depart from linearity, indicating a small amount of material which has not been strongly affected by the heat treatment. Thus, the present results show that some crystallites retain a large misorientation, grow very little, and remain highly disordered even after heating at 3,000° C.

A sharp change in layer stacking order in some temperature range above 2,000° C, such as that shown in Fig 2, is commonly observed in all graphitization processes. Franklin[9] has suggested that crystallites in graphitizing carbons grow by displacement of whole layer planes or even groups of layers and that graphitization occurs because of high internal thermal stresses set up during thermal treatment. The latter concept has been developed in some detail by Tsuzuku[10], Mizushima[11] and Mrozowski[12]. Tsuzuku showed that in spherical or cylindrical structures temperatures around 2,500° C can produce stress concentrations sufficient to buckle the crystal lattice. Stress relief can occur by the generation of dislocations or rearrangement of the turbostratic crystallites into the three-dimensional graphite lattice. Tsuzuku's theory predicts a minimum crystallite size of about 200 Å, below which thermal stresses cannot be relieved by generation of dislocations, but cause fracture instead.

The present work shows that orientation-dependent changes of layer stacking order during heat treatment are an integral part of the graphitization process in pyrolytic graphite. A stress relief mechanism seems most consistent with the observed behaviour. Stresses are developed because individual crystallites have a large anisotropy in their thermal expansion coefficients, and experience an average strain field which is also anisotropic. No estimates of the resulting stresses or strains are available, but an orientation dependence is clearly implied. It has already been demonstrated in other experiments that tensile straining parallel to the deposition surface enhances the ordering process[13]. Consequently, it seems likely that in heated pyrolytic graphite the resulting local stress distributions are such that the largest stresses parallel to layer planes are experienced by those crystallites tilted least away from the original

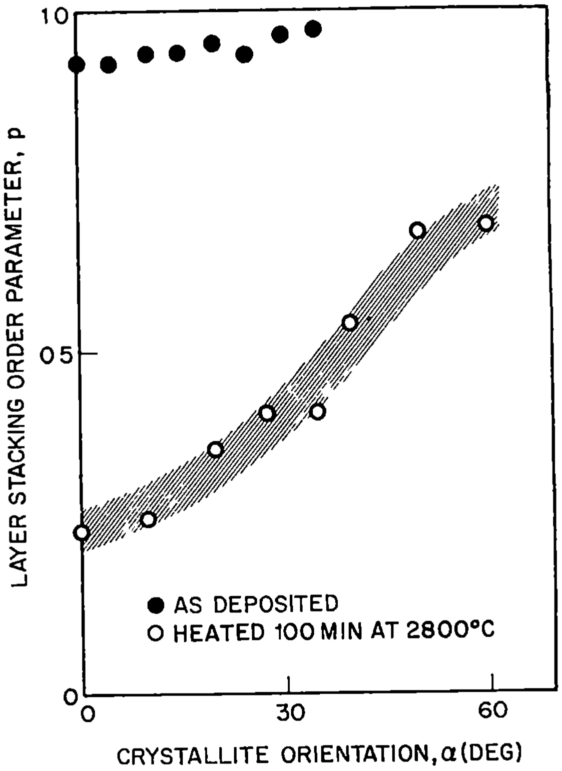

Fig 3 Variation of layer stacking order parameter with crystallite orientation

deposition surface The need for more quantitative experiments relative to this orientation dependence and an analysis of the local stress distribution in this situation is clearly indicated

The variation of order parameter with crystallite tilt angle shown in Fig 3 has the important consequence that the usual method of X-ray residual stress determinations cannot be applied to pyrolytic graphite The method depends on interpreting a variation of interplanar spacings with orientation as being due to strains alone The residual stresses are inferred from these strains by an equation which involves the observed strains and Poisson's ratio Since in pyrolytic graphite the variation of interplanar spacings with orientation can be an indication of ordering as well as strain, the usual method of residual stress determinations cannot be used This does not preclude use of an empirical correlation between X-ray line shifts and applied loads in studies of incremental stress-strain behaviour of a particular specimen, but such results could not be used in determining strains in other specimens

FLUCTUATIONS OF GROUND-WATER LEVELS DUE TO ATMOSPHERIC PRESSURE CHANGES FROM NUCLEAR EXPLOSIONS

By Dr J INESON

Water Division, Geological Survey of Great Britain, London

THE effects of the nuclear explosions by the U S S R at Novaya Zemlya in October 1961 on atmospheric pressure disturbances in Great Britain[1-3] and in New Zealand[4] have already been reported

Automatic float-operated water-level recorders have been installed at a number of wells sunk into a variety of aquifers in England[5] They are used primarily for the investigation of seasonal and long-term variations in ground-water levels The recording-rate does not usually exceed 1·2 in /day and the water-level fluctuations are transmitted through a system of reduction gears ranging from 1 1 to 1 20 The hydrographs (traces of the fluctuations of ground-water levels) are investigated for macro- and micro-fluctuations

An examination of the hydrographs from certain wells sunk into Chalk, Lower Greensand and Jurassic limestones in southern England has confirmed rapid responses of ground-water levels to atmospheric pressure changes arising from the nuclear explosions of October 23 and 30, 1961 The maximum recorded fluctuation in ground-water level was about 0 02 ft in a Chalk well, although fluctuations of less than 0 01 ft are more common The hydrograph from a Chalk well at Wested, Kent (*TQ* 518668), shows a rapid fluctuation of ground-water level of about 0 015 ft just before noon on October 30, part of this hydrograph from October 30 to November 2, 1961 (inclusive), is reproduced in Fig 1*a* This fluctuation corresponds to the arrival of the direct pressure wave, the maximum peak to trough amplitude recorded on the microbarogram at Kew Observatory being about 900–1,000 microbars Successive reflexions of the pressure waves at the antipodes of Novaya Zemlya and at Novaya Zemlya itself were recorded at Foulness[2], Edinburgh[3] and at Kew Observatory (Fig 1*a*) The changes in pressure due to these reflexions affected ground-water levels up to November 2, being particularly well developed on the Wested hydrograph for October 31 and November 1 All wells recording the effect of the direct wave did not necessarily show every reflexion No positive evidence of reflexions after November 2 has been obtained

One automatic water-level recorder was installed on a Chalk well at Wheathampstead, Hertfordshire (*TL* 172145), with a recording time-scale of 0 4 in /h At about 1150 G M T , October 30, 1961, the hydrograph was interrupted by a clearly defined anomalous fluctuation in ground-water level comprising a fall, then a rise, succeeded by a fall in water-level to about the same level as before the anomaly The maximum trough to peak amplitude was about 0 02 ft This pattern is the mirror image of the initial stage of the pressure changes recorded on the microbarogram

The effect of the nuclear explosion on October 23, 1961, is less pronounced due to the smaller magnitude of the micropressure disturbances Fig 1*b* shows the hydrograph for the Wested well during the period October 22–25, 1961 (inclusive), the fluctuations in ground-water level just before noon on October 23 correspond to the arrival of the direct wave The maximum peak to trough amplitude at Kew Observatory was about 350 microbars Ground-water fluctuations due to reflexions are also present on October 24 and 26

The effect of changes in atmospheric pressure on ground-water levels is well demonstrated during this same period, as illustrated by Fig 1c, which is part of the corresponding barogram obtained at South Kensington, London, the reciprocal nature of atmospheric pressure variations and ground-water fluctuations is apparent In addition to the microfluctuations of ground-water levels resulting from the nuclear explosion on October 23, an anomaly occurred just before midnight October 22–23, 1961, a period associated with marked climatic changes, for the microbarogram at Kew Observatory shows a pronounced angular rise in atmospheric pressure (about

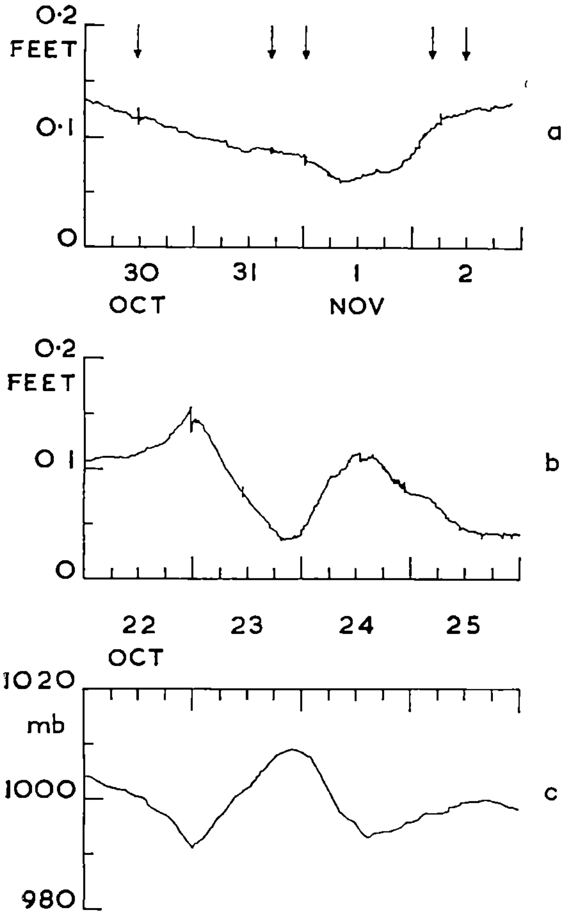

Fig 1a and b Ground-water fluctuations in Chalk well at Wested, Kent, a, between October 30 and November 2, the arrows indicate the onset of the direct atmospheric pressure wave and its reflexions, arising from the nuclear explosion by the U S.S.R, as recorded at Kew Observatory, b, between October 22 and 25, 1961 Fig 1c Barogram from South Kensington, London, between October 22 and 25, 1961

1,300 microbars) at about 2337 G M T, October 22, 1961 The pressure later declined gradually over the succeeding 1½ h· This pattern is faithfully reproduced in the ground-water fluctuation, again confirming the effect of microbarometric pressure changes

No positive evidence has been obtained of the effect of other nuclear explosions on ground-water levels, probably due to their lower range

The relationship between gradual changes in atmospheric pressure and fluctuations in ground-water levels can be determined over a period of time For the Wested well (Fig 1) an approximate value of 0 008 ft fluctuation in water-level is caused by a change in one millibar of atmospheric pressure The fluctuations of ground-water levels discussed here, due to rapid changes in atmospheric pressure, suggest a somewhat higher ratio (about double) This may be due either to the type of instrument used (a horizontal rotating drum to record water-level changes) or to a real effect with an almost instantaneous pressure-differential being created

Changes in barometric pressure influence the elastic state of a confined aquifer The magnitude of the effect depends on the pressure differential, the elastic properties of the aquifer and the degree to which confined conditions of ground-water flow exist in that aquifer As the aquifer responds elastically to these external pressure variations, the porosity and intrinsic permeability of the water-bearing material change with the movement of ground water into or out of the effective pore spaces, associated with fluctuations in water-levels In addition to ground-water fluctuations in confined aquifers due to this series of nuclear explosions, similar anomalies have been identified in so-called 'water-table' aquifers, as, for example, the Wested well in Chalk referred to here Two conclusions can be drawn, such aquifers are in fact confined or consist of a series of semi-confined aquifers, or unconfined aquifers do respond to changes in atmospheric pressure The former is probably applicable to the examples studied More detailed investigations are necessary to consider the second possibility

Microfluctuations of ground-water levels due to earthquake waves have been recorded in Great Britain[6], confirming the elastic state of an aquifer The arrival time of seismic waves arising from the nuclear explosion of October 30, 1961, would be about 0840 G M T in southern England[1] So far as is known, no record of these waves has been identified on ground-water hydrographs in Great Britain

Although the present use of automatic water-level recorders is generally restricted to relatively long-period traverses, rapid time traverses (up to 4 8 m / min) have been adopted for particular problems The form of ground-water fluctuations (corresponding to changes in the elastic state of an aquifer) due to seismic waves and atmospheric micropressure changes from nuclear explosions and other causes could be established, but the precise time of onset of these fluctuations cannot be catered for with the present equipment Microfluctuations of ground-water levels could be measured continuously by pressure transducers and other instruments recording electronically on magnetic tape, the form of the fluctuations being analysed afterwards The structural properties of aquifers can be elucidated more accurately by an analysis of ground-water fluctuations Since the elastic properties of an aquifer are implicit in all confined ground-water flow conditions, more intensive investigations by means of continuously recording equipment, suitably located, should contribute to a better understanding of aquifer properties and to the study of the availability of ground-water resources

Note added in proof Ground-water fluctuations arising from the atmospheric pressure waves created by the nuclear explosion on August 5, 1962, by the U S S R have been recorded over a wider area than after previous explosions The maximum recorded change in ground-water level was 0 045 ft in a Chalk well, this is double that in October 1961 The maximum peak to trough amplitude recorded on the microbarograph at Kew Observatory was about 1,300 microbars No reflexions of the atmospheric pressure waves were identified on ground-water hydrographs on August 6 and 7 This may be due to the subdued nature of the pressure changes and to a pronounced rise in ground-water levels on August 6, 1962, the result of a general reduction in barometric pressure

RADIOPHYSICS

Faraday Rotation Effects associated with the Radio Source Centaurus *A*

Recent observations[1,2] with the 210-ft. telescope of the Australian National Radio Astronomy Observatory have revealed the existence of linearly polarized radiation from the source Centaurus *A* at frequencies of 3,000 Mc/s and 1,410 Mc/s.

This communication reports investigation of Faraday rotation effects associated with this radiation. Measurements have been carried out at frequencies ranging from 970 Mc/s to 3,000 Mc/s at a number of points in the source. The points, the coordinates of which are given in Table 1, are located in the bright central component and in the northern and southern extensions of the source. The observing methods were essentially those of Gardner and Whiteoak[2].

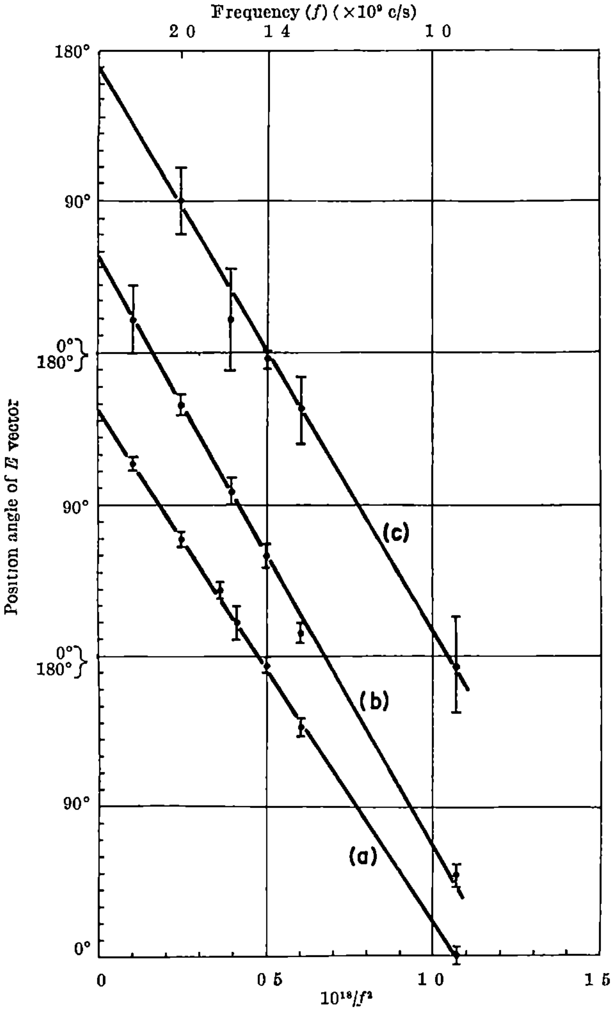

Fig. 1. Frequency dependence of the polarization position angle at three points in Centaurus *A*. *f*, Frequency in c/s. *a*, R.A. 13h 23m 15s, declination −42° 48.5′; *b*, R.A. 13h 24m 00s, declination −42° 30′; *c*, R.A. 13h 20m 30s, declination −44° 25′. Curve *c* has been arbitrarily displaced upwards by 180° relative to *a* and *b*.

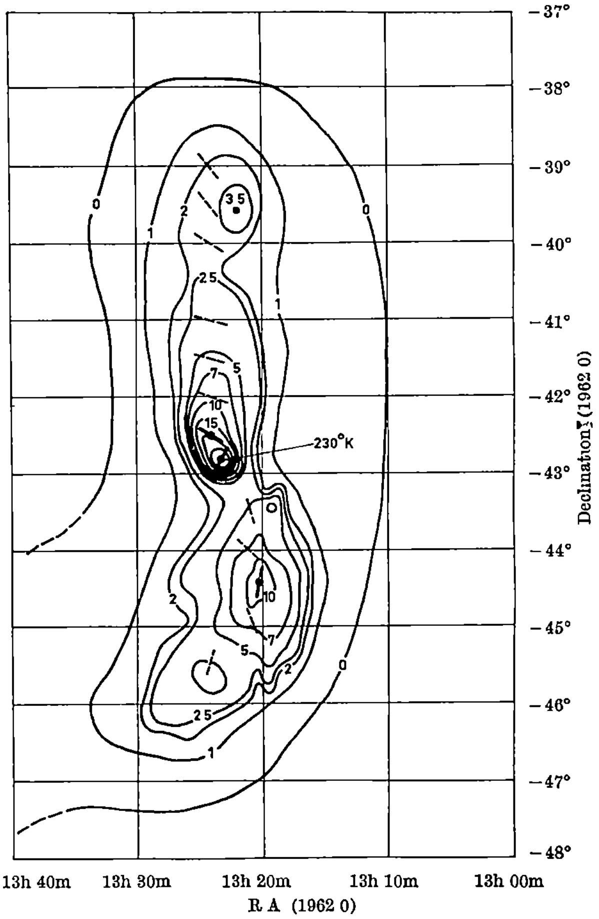

Fig. 2. Isophotes of Centaurus *A* at 1,410 Mc/s in deg. K. The short solid lines show the direction of the electric vector corrected for Faraday rotation at the three points quoted in Fig. 1. Also shown dotted are directions of the electric vector at several other points as observed at 1,410 Mc/s. Aerial beam-width is 13.5′ to half-power points.

Table 1 lists the observing frequencies and the position angle of the electric vector observed at the various points. The percentage of linear polarization is also given.

In Fig. 1 the position angle of the electric vector is plotted against a frequency variable $10^{18}/f^2$ for the three quoted points in the source. It is seen that, within the experimental error, the position angle has a $1/f^2$ dependence, as expected for the Faraday effect, the agreement being particularly good for the central component. Thus the position angle corresponding to $f = \infty$ should be the true polarization angle at the source. It is also to be noted that the rotation is in the same sense at all three observed points and the slopes of the three curves do not differ greatly from each other. Curve *a* exhibits a total rotation from 1,000 Mc/s to infinite frequency of 306°, curve *b*, 350°, and curve *c*, 344°.

Table 1 FARADAY ROTATION

Frequency (Mc/s)	Beam-width (min of arc)	R A 13h 20m 30s Dec −44° 25′		Central component R A 13h 23m 15s Dec −42° 48 5′		R A 13h 24m 00s Dec −42° 30′		R A 13h 24m 00s Dec −42° 10′	
		Position angle	Per cent	Position angle	Per cent	Position angle	Per cent	Position angle	Per cent
3,000	6 7			115° ± 3°	15 ± 2	20° ± 20°	45 ± 15		
2,000	10 0	90° ± 20°	28 ± 5	70° ± 3°	8 ± 4	150° ± 3°	45 ± 5		
1,650				40° ± 4°	9 ± 4				
1,575		20° ± 30°	27 ± 5			98° ± 7°	30 ± 3		
1,550				20° ± 10°	6 ± 4				
1,410	13 5	175° ± 5°	15 ± 5	175° ± 3°	7 ± 2	60° ± 5°	30 ± 5	71° ± 5°	30 ± 5
1,280		147° ± 20°	20 ± 5	138° ± 4°	6 ± 3	15° ± 3°	24 ± 4		
970	20 0	174° ± 30°	18 ± 10	180° ± 5°	3 ± 1	49° ± 3° (at −42° 20′)	19 ± 3	50° ± 5°	17 ± 4

At 970 Mc/s a receiver was used which passed two sidebands separated by 60 Mc/s It can be deduced from Fig 1 that the differential rotation between these sidebands amounted to about 45°, so that the true degree of linear polarization was approximately 10 per cent higher than that observed It is interesting to note that receiver band-width needs to be severely restricted from polarization observations of Centaurus *A* at lower frequencies since the band-width depolarization effect goes as $1/f^3$

A complete survey of the source has now been made at 1,410 Mc/s with a sensitive parametric receiver and analysis of the observations is in progress Fig 2 is a preliminary sketch of the isophotes with a superimposed indication of the direction of polarization at the three observed points, corrected for Faraday rotation It has been known for some time that the central component consists of two small sources lying on a line in position angle ~ 45° and separated by 7 minutes of arc, and as shown by Bracewell, Cooper and Cousins[1] only the north-east source is polarized The present determination of 147° for the polarization position angle at the north-east source places its electric vector roughly at right angles to the line joining the two sources

At the two points examined in the extended source the polarization runs approximately in the direction of the extension, but this orientation may not be too well maintained over the whole extended source Although linear polarization has been detected at 1,410 Mc/s over the whole area covered by the source, the Faraday rotation measurements have been made only at the three quoted points where a satisfactory signal-to-noise ratio could be obtained with simple receivers tunable over a wide frequency-range

The observed Faraday rotation is nearly two orders of magnitude greater than can be ascribed to ionospheric effects. Evans[3], for example, has measured a one-way Faraday rotation in the ionosphere above Jodrell Bank of approximately 720° at 120 Mc/s at 08 h local time If similar ionospheric conditions apply to the present measurements the ionospheric Faraday rotation can be no more than 10° at 1,000 Mc/s In the present measurements no significant variation of the polarization angle has been observed between the afternoon hours and midnight, as would be expected if the ionosphere were playing a considerable part Hence the majority of the rotation must be occurring either within our own Galaxy or in the outer regions of Centaurus *A*

The amount of Faraday rotation to be expected from a cloud of electrons of concentration N_e (cm^{-3}) situated in a magnetic field H (gauss), which is uniformly oriented over a path-length L cm at an angle α to the line of sight, is given by

$$\psi = 2\ 36 \times 10^4 N_e H L f^{-2} \cos \alpha \text{ radians}$$

where f is the frequency of the radiation in cycles per second

For the observed amount of rotation a value of the product $N_e HL \cos \alpha$ of $\sim 2\ 5 \times 10^{14}$ is required Since the galactic co-ordinates of Centaurus *A* are $l^{\rm II} \approx 320°$, $b^{\rm II} \approx + 20°$ the radiation from the source travels for a considerable distance through the galactic corona If the rotation is to occur in this region we may put $L \approx 10$ kiloparsecs, $H \approx 10^{-5}$ gauss and for the highly favourable case of $\alpha = 0$ over the whole 10-kiloparsec distance we need an electron density of 7×10^{-4} cm^{-3} This value is feasible, but the requirement of uniformity of the magnetic field over such a great distance raises serious doubt that the rotation can be occurring in this region

On the other hand, if the rotation is occurring in the outer regions of Centaurus *A* the effect is, again, remarkably uniform over great distances At an assumed distance of 4 megaparsecs the three regions investigated cover a distance of 160 kiloparsecs transverse to the line of sight However, the 1,410 Mc/s survey referred to earlier is revealing that the polarization angle is itself fairly constant over some quite large distances in the source, so that the possibility of a substantially constant Faraday rotation in the outer regions of the source cannot be ruled out entirely

Investigation of Faraday rotation effects in other polarized extra-galactic sources may shed more light on the problem and will be awaited with much interest

We thank our colleagues whose joint efforts have made these observations possible, and in particular Mr J G Bolton and Dr F J Kerr for helpful advice and criticism One of us (R M P) is the recipient of a Fulbright Fellowship

Cyclotron Theory of Very-Low-Frequency Discrete Emissions

It was recently shown[1] that the Doppler shifted cyclotron radiation from receding electrons would give the observed frequency-time shape of discrete very-low-frequency emissions A further development enables information about these electrons to be deduced from this shape. Thus, electron energy (E), initial helical pitch angle (ψ_0), geomagnetic field line of occurrence (λ), and the exosphere electron density parameter[2], 'scale frequency' (f_a), are obtained from four parameters (two frequencies and two times) scaled from a spectrogram of the emission. Full details of this process will be published elsewhere

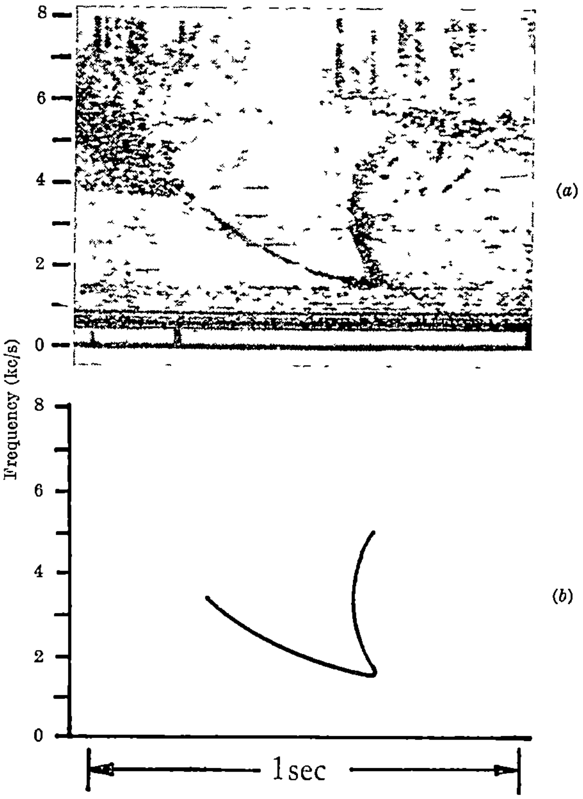

Fig 1 *a*, 'Hook' recorded at Seattle, on September 23, 1957, at 2035 28 U T (after Helliwell and Carpenter, ref 6), *b*, as calculated from the theory (ref 1) for E = 150 keV, ψ_0 = 68 6°, λ = 61 4° and f_a = 527 kc/s

As a demonstration, consider the 'hook' shown in Fig 1*a* The location of three points in the frequency-time plane unambiguously requires E = 150 keV, ψ_0 = 68 6°, λ = 61 4° and f_a = 527 kc/s To test the theory, 25 points were calculated from first principles using this information The curve through these points is shown in Fig 1*b* Comparison shows excellent agreement

The theory[1] explains other types of discrete emissions as special cases of 'hooks' In particular, the theory predicted a repetitive type of emission not previously recognized This occurs when the electron bunch survives several hemisphere to hemisphere traverses or 'bounces' between magnetic mirror points The emission appears as a succession of similar hooks separated by the bounce period of the electrons It is readily distinguished from whistler mode echoes of a single hook since successive hooks are not progressively more dispersed according to their order in the sequence Since the observable radiation is unidirectional the hooks are received in opposite hemispheres alternately, that is, the sequence observed in one hemisphere is displaced half a bounce period from that observed in the other This effect distinguishes the predicted emission from some other effect such as periodic injection of electrons

Observation of this predicted emission showing a bounce period consistent with E, ψ_0, and λ scaled from the shape would be a crucial test of the theory both qualitatively and quantitatively

A sequence which was probably of this predicted type was recently discussed[3] It appeared as two bursts of 5–6 kc/s noise (presumably parts of a single hook) seen three times It was observed in both hemispheres, not simultaneously, but alternately as explained here Since only a narrow frequency band was observed the progressive dispersion criterion could not be applied However, the recurrence period was consistent with a bounce period for electrons of typical energies as deduced from other hooks, but only a half to a third of typical whistler mode echo, delay times at this frequency On the other hand, in a reply[4], Helliwell pointed out that whistler delay times can be sufficiently small during magnetic storms so that in this case the echo possibility cannot be ruled out

I have since noticed four clear-cut examples published by Gallet[5] In each of these there was a striking lack of progressive dispersion despite the considerable frequency extent of the hooks and the relatively large number of separate hooks (six, in one sequence) Gallet[5] remarked on this at the time Table 1 shows E, ψ_0 and λ deduced from the shape of one of the hooks for each sequence The expected bounce periods calculated from E, ψ_0 and λ are shown as P_c and the observed periods (as measured by Gallet) are shown as P_0 The spectrograms as published[5] are rather small for accurate scaling so that the probable error in P_c is rather large However, the general agreement is quite good

Table 1 COMPARISON OF OBSERVED RECURRENCE PERIOD (P_0) WITH THAT CALCULATED (P_c) FROM E, ψ_0 AND λ DEDUCED FROM THE FREQUENCY-TIME SHAPE

Sequence No	No of hooks in each sequence	Energy (E) (keV)	Helical pitch ψ_0	Geomagnetic latitude λ	Calculated period P_c (sec)	Observed period P_0 (sec)
1	3	14	70°	59°	1 2	1 6
2	6	8	62°	59°	1 7	1 6
3	2	15	72°	59°	1 1	1 6
4	3	5	48°	59°	2 1	1 6

The electron cyclotron theory gives excellent agreement with the observed frequency-time shape of discrete emissions In addition, the predicted periodic emission is shown to occur and with periods reasonably close to those predicted Verification of the theory not only clears up a mystery of long standing but also justifies the use of spectrograms of emissions for finding information about the electrons which produce them Large numbers of such spectrograms were recorded during the International Geophysical Year

I thank Prof G R A Ellis for advice

PHYSICS

Stark Effect Broadening of the Krypton Lines and Emission of the Kr_2^+ Molecule

IN the investigation of the asymmetrical broadening of atomic lines of inert gases, one usually neglects other perturbations such as the formation of unstable molecules from excited and normal atoms Most molecules bound by Van der Waals forces produce bands on the shorter wave-length side of the line,

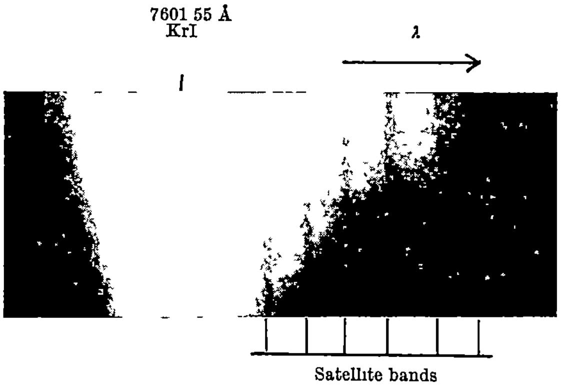

Fig 1

while the external electric field shifts the line towards the longer wave-lengths

There are numerous observations of absorption satellite bands appearing in the presence of foreign gases on the red side of the principal series of the alkali metals[1] Their intensity increases with the polarizability of the foreign gas In emission, complex bands appear on both sides of some mercury lines in the presence of inert gases at high pressure[2]

So far as inert gas molecules are concerned, only He_2 spectra are well known For other inert gases continuous bands are emitted either in the positive column or in the arc It has been assumed that diatomic molecules like Kr_2 were responsible for these intensity fluctuations[3] However, no spectroscopic analysis is available to support this interpretation

So far as we know, the molecular emission analysed in this communication is the first to verify by spectroscopic means the existence of Kr_2 or Kr_2^+ molecules

The discharge lamp used to excite the Kr_2 and Kr_2^+ spectra was made of a thick glass bulb of 2 cm diameter having two 2-mm diameter tungsten electrodes separated by 5 mm This bulb was thoroughly pumped out, and then filled with pure commercial krypton supplied in glass containers by the Liquid Air Co This gas was first liquefied under reduced pressure at liquid nitrogen temperature, and then warmed up until the pressure reached 10 atmospheres The discharge current of a few m amp was supplied by a 4,000-V d -c generator and the emission photographed with a Jaco-Ebert 3 4-m spectrograph having a dispersion of 3 24 Å per mm at 7500 Å

Fig 1 shows an enlarged print of the broadened KrI λ7601 55 Å ($1s_5$–$2p_6$) line Like most of the other lines, it is shaded to the red Its intensity decreases very rapidly with the wave-length It is not easy to decide whether the observed structure is due to re-absorption or to emission An attempt to find an absorption spectrum using a second continuous emission lamp failed Therefore, we will assume that the intensity fluctuations are true emission bands From rough wave-length measurements of the intensity minima the successive band intervals are (in cm^{-1}) 1 89, 1 98, 1 95, 2 08, 2 39, 2 06, 2 38, 2 32 Secondary minima may also be seen showing frequency intervals of 1–1 25 cm^{-1}

If the emitting molecule were diatomic one would have a choice between the following interpretations

(1) The bands are due to an unstable Van der Waals-like molecule The spacing between the most intense bands, of the order of 2 cm^{-1}, may then be explained as originating from a transition between a fixed upper vibrational level and a variable vibrational level of the lower electronic state The vibrational frequency of 2 cm^{-1} would then correspond to a dissociation energy of about 0 005 eV, which is unusually small

(2) The bands are a portion of a sequence located near the turning point In this case, the frequency difference could be represented by

$$\Delta\nu = 2(\omega_e' x_e' v' - \omega_e'' x_e'' v'')$$

Here the observed frequency difference (2 cm^{-1}) does not give any precise information on the molecular stability

In the first approximation the lines are simply shaded to the red It is natural, first of all, to think in terms of asymmetrical broadening by the ions and electrons through the quadratic Stark effect There may be no fundamental difference between the emission of a weakly bound excited Kr_2^+ molecule and the emission of a line broadened by intermolecular Stark effect Since the effect of the electric field is larger for the $2p_6$ excited state than for the $1s_5$ metastable state, the band system corresponding to the transition

$$[Kr\,(2p_6) + Kr^+\,(4s^2\,4p^5)] \rightarrow [Kr\,(1s_5) + Kr^+\,(4s^2\,4p^5)]$$

then would lay-out on the long wave-length side of the non-perturbed line, just as the atomic line is asymmetrically broadened by electric fields

The Kr_2^+ molecule has been found in its fundamental state in mass spectrometer investigations of a partially ionized plasma[4] The Kr_3^+ and Kr_4^+ complex ions have also been observed From an analysis of ionic mobilities it is found that the ionic equilibrium is shifted towards the ions with a larger number of atoms Thus the complicated structure of the emission bands may be due to a polyatomic molecule However, such a molecule is usually less stable in an excited state than is the normal one, contrary to what is observed here Indeed, the shading towards the red of the bands corresponds to a higher stability of the upper excited state The attraction force between the excited Kr ($2p_6$) atom and the Kr^+ ion can easily be estimated from the quadratic Stark effect constants, and is much larger than the Van der Waals force between the same atoms It is difficult to build up a spectroscopically detectable number of Kr_2^+ molecules because for small intermolecular distances they dissociate through the interaction between the potential energy curves, while, on the other hand, when the electric field intensity is sufficiently high or the distance between the ion and the excited atom small enough, pre-ionization may occur The atomic state vanishes and so does the corresponding molecular state

Margenau and Klein[5] have attempted to interpret some of the emission satellite bands At low inert gas pressures, one usually observes violet bands which are generally the consequence of the transition from an upper vibrational level formed by collision (for example, between Kr and Kr^+) located near the dissociation limit to different vibrational levels of the lower electronic state As the pressure increases, collisions will build up the population of the lower vibrational levels of the excited electronic state, and shift the emission towards longer wave-lengths Thus, one is brought back to the hypothesis of a molecular transition between high vibrational levels In the present case, the absence of violet bands would indicate that we are concerned with Kr_2^+ and not Kr_2 molecules since, in the case of metallic lines emitted in presence of inert gases, one observes intense violet bands Such bands may be due to neutral Van der Waals molecules the polarizability of which is smaller for the more excited state For the 7601 55 Å line with which we are concerned here, the violet bands are practically absent This is in agreement with the fact that the Stark effect constant is larger for the more excited state.

To sum up, in usual discharges at high ion densities, as in arcs or sparks, the temperature of the gas is so high that most of the neutral or ionized molecules are dissociated But when the ionic concentration is high, at low gas temperatures, the contribution of molecular ion emission may be detectable

Interpretation of Quantum Physics

ATTENTION has been directed to persistent questions of interpretation in quantum physics by the recent exchange of views[1] on the subject between Dr H V. Stopes-Roe and Prof A Landé To Prof Landé's picture[2] of the particle as permanently localized phenomenon, influenced through action-at-a-distance by the extended structure of a measuring instrument, Dr Stopes-Roe understandably objects that a necessarily detailed and 'suitable interpretation of the collective action of the apparatus' has not been provided Prof Landé's failure to furnish such an interpretation is equally understandable, since any interpretational superstructure in physics that lacks roots in the underlying mathematical formalism (cf the luminiferous ether) tends sooner or later to be viewed as excess ideological ballast

Those who believe, however, that all ballast of this kind has been jettisoned from the present most widely accepted version of quantum mechanics should reflect on the absence of a necessary basis[3] in the existing quantum mechanical formalism for the conceptual device known as 'reduction of the wave packet', by which device most physicists reconcile their natural prejudice that events 'really happen' with the fact that the equations of quantum mechanics contain no parameters descriptive of events (as such) and hence rigorously deny respectability to the concept of 'event'

Perhaps the most harrowing questions, then, that plague contemporary quantum physics are not those concerning the 'wave-particle dualism', which bear on the loss of causality (trajectory definability) in any system described by a wave function, but those concerning objectivity (event definability) and the proper severing-point of the 'von Neumann chain'[4] connecting the thing observed with the mind of the observer Several deep-going paradoxes[5], which strike to the foundation of physics as a non-solipcist discipline, arise if (as is now customarily done) the non-mechanical element 'mind', which appears in none of the equations, is adduced as necessary ballast in mechanical description

It is the purpose of this communication to point out that there is an altogether different approach to interpretational problems and paradoxes in quantum physics, by which one directly attacks the mathematical formalism itself, rather than the words that are said about it By this approach one can take advantage of the epistemological leverage exerted by the formalism, whereby the gentlest modification of the mathematics characteristically engenders the most drastic changes in the interpretation

Until recently the formalism of quantum mechanics was considered proof against all modifications except such as would spoil its excellent agreement with experiment However, it has now been shown[6] that a perfecting of the formal correspondence (with Hamilton-Jacobi mechanics) by which the quantum-mechanical equations of motion are derived leads to a generalized form of the latter The solutions of the generalized equations corresponding to ordinary quantum mechanical states are identical with the familiar Schrodinger or Dirac solutions except for the attachment to the wave function of a constant phase factor, for example, of the form $\exp[-(i/\hbar)\Sigma_k P_k X_k]$ The X_k and P_k are constants, formal analogues of the 'initial conditions' constants that appear in the classical theory (as parameters descriptive of the event by which a classical state of motion is entered or produced)

The constancy of the phase factor implies its general unobservability (absorption into the wave-function normalization factor) Thus, the description of stationary states and non-contingent events is the same in the generalized theory as in the customary one However, the appearance of new parameters that may be considered to describe the event (or world point) by which a system enters a new state, or changes its state, puts an altogether new complexion on many matters of interpretation Not only is the 'event' concept, which is virtually indispensable to relativity theory, rendered for the first time respectable in quantum theory, but the hitherto nebulous and controversial idea of 'quantum jump' is given an explicit formal-descriptive characterization, as reflecting a discontinuous jump in the value of the phase factor (a jump that 'reduces' not the wave packet but the wave function itself) Only the fact that changes in the X_k, P_k occur is physically significant, not the magnitudes of these parameters The von Neumann chain is severed wherever and whenever an event, or localized particulate interaction (as distinguished from non-local interactions with extended structures), occurs That individual-particulate events seem to occur physically (for example, scintillations of a fluorescent screen, decay of single radioactive atoms) and to occur independently of cognition has always been undeniable Now, if we like, we can aver that appearances are not deceptive

With the re-entry into the formalism of parameters specifically descriptive of events, objectivity is restored, and 'mind' ceases to play a non-classical role Observation, as in classical mechanics, produces no disturbance incompatible with equations of motion, and the latter now suffice for physical description without need or place for non-mechanical additives On the other hand, the fact that the development of a system in time is described by a wave function implies non-restoration of causality The basic facts of Bohr's 'complementarity' remain unaltered World points and objectivity are re-established, world lines and causal pictorializations of trajectories are not This variety of formal 'completion' of quantum mechanics leaves God (in Einstein's figure of speech) playing dice with the world, but the fall of dice no longer depends for consummation on the merciful presence of an observing mind

In summary, it would appear permissible to view the world as a lattice of discrete space-time event points, existing independently of observation, as was true in classical physics But the classical option of causally connecting the lattice world points by continuous world lines appears fruitless to pursue, and this fruitlessness remains the hall-mark of quantum physics Even the limited return to classical precepts envisioned here seems unattainable within the existing formalism of ordinary quantum mechanics Rather, the formalism itself must be modified, in a way that affects none of the simpler agreements with experiment, but that drastically affects the theory of measurement (that is, theory of contingent events) The question of possible comparison with experiment of an altered theory of measurement has been touched on elsewhere[7] The matter will bear further study

In a previous communication[1] I asked Prof Landé to fill out certain details of his interpretation of quantum physics, namely, the mode of action of a certain piece of apparatus I described Dr Phipps now suggests that I was demanding that Prof Landé give some sort of ether type model This was not at all my intention—I was asking him to describe the apparatus in whatever terms were appropriate to his approach I could not see how this could consistently be achieved, and I therefore asked for enlightenment

Prof Landé's reply[2] to my question does not meet the problem He appeals to the fact that collective action 'is always taken for granted' in contemporary quantum theory, but the general acceptance of collective action rests on the general acceptance of non-simply-localized 'particles'—which Prof Landé specifically rejects

The spread mode of action between 'particle' and environment is an important experimental feature, and it must be given explicit recognition Broadly there are three ways of approaching a treatment (apart from anything radically new, as for example some of Bohm's recent ideas)

(1) The 'particle' has a spread quality, (2) The environment acts collectively, (3) Action at a distance between the two, by an intervening medium, by a field

The first (with complementarity) is the classical quantum view, the second indicates Landé's approach, the third is illustrated by Bohm in his earlier period But 1, 2 and 3 characterize programmes for theory construction, not theories What is it for the three bits of metal I described to 'act collectively' in the very special way required ? Talk of a crystal or a gas makes the given problem look simpler by adding irrelevant features which serve only to confuse The difficulty is not simply the relativistic one of instantaneity in general, nor simply the mechanical one of perfect rigidity, this will be recognized if the example is examined in detail

Dr Phipps, in the major part of his communication, leaves the problem of localization and asks 'What constitutes an event ?' I will not follow him now

Effect of Adsorbent Temperature on the Brunauer–Emmett–Teller Surface Area determined by Krypton Adsorption at 77° K

In a recent paper on the use of krypton adsorption at low temperatures as a method of determining Brunauer–Emmett–Teller (B E T) surface areas, Haynes[1] has shown that the monolayer volume, v_m is dependent on the value chosen for the saturation vapour pressure of krypton, p_0, and has pointed out that if a 'wrong' value of p_0 is used a B E T plot which is curved in the monolayer region will result In particular, the use of the vapour pressure of solid krypton in the monolayer region can lead to curved B E T plots, though this difficulty can usually be largely, if not completely, overcome by using instead the extrapolated liquid vapour pressure as has been recommended by Beebe, Beckwith and Honig[2]

There is, however, another factor which may cause a 'wrong' vapour pressure to be used, so giving B E T plots which are curved within the monolayer region Moreau[3] has reported that in determinations of B E T surface areas by nitrogen adsorption at 77° K the adsorbent may be at a higher temperature than the surrounding refrigerant Temperatures, measured in three samples 20 min after nitrogen had been admitted to the apparatus at a pressure of 100 mm mercury, were between 1 8 and 2 3° K higher than that of the surrounding liquid nitrogen If the saturation vapour pressure of nitrogen corresponding to the liquid nitrogen temperature is used in the B E T calculation, it will be lower than that corresponding to the adsorbent temperature by 20–25 per cent and this will in turn influence the value of v_m and hence the surface area calculated from it Depending on the adsorbent, the B E T plot may also then show curvature, which in this case will be convex to the relative pressure axis, within the monolayer region

The effect of similar temperature differences on the extrapolated liquid vapour pressure of krypton at 77° K will be more marked than in the case of nitrogen on account of the higher heat of vaporization of the former as can be seen from Table 1, in which the vapour pressures have been calculated from the equation proposed by Meihuizen and Crommelin[4]

The change in temperature from 77 4° K to 79 4° K increases the liquid vapour pressure by about 55 per cent and hence the effect on the B E T plot of a 2° K

Table 1 VARIATION OF EXTRAPOLATED LIQUID VAPOUR PRESSURE OF KRYPTON WITH TEMPERATURE

T ° K	77 4	77 8	78 2	78 6	79 0	79 4
p_0 mm mercury	2 514	2 748	3 001	3 274	3 567	3 883

uncertainty in the adsorbent temperature will be at least as great as that caused by using the solid rather than the extrapolated liquid vapour pressure

To show the effect of such changes in vapour pressure, determinations of the surface area of a uranium trioxide and of a uranium dioxide powder were recalculated taking in turn 3 000, 3 500 and 4 000 mm mercury as the vapour pressure of liquid krypton at the adsorbent temperature Both adsorbents gave B E T plots which were linear in the monolayer region when the liquid vapour pressure corresponding to liquid nitrogen temperature was used in the calculations For the uranium trioxide, deviation from linearity was barely perceptible with a vapour pressure of 3 000 mm mercury, but at the two higher pressures there was obvious curvature, concave to the relative pressure axis In the case of the uranium dioxide which has a lower *c* value, 30 as against 150 for the trioxide, curvature was apparent at all three pressures The temperatures corresponding to these vapour pressures, the monolayer volumes calculated by drawing tangents to the B E T curves, and the corresponding B E T surface areas are shown in Table 2

Table 2 CHANGE OF B E T SURFACE AREA WITH KRYPTON VAPOUR PRESSURE

p_0 (mm mercury)	Corresponding temperature (° K)	v_m (ml)	Surface area (m²/g)
		Uranium trioxide (200 mg)	
2 553	77 5	0 416	10 8
3 000	78 2	0 432	11 2
3 500	78 9	0 445	11 6
4 000	79 5	0 463	12 0
		Uranium dioxide (406 mg)	
2 558	77 5	0 185	2 37
3 000	78 2	0 190	2 44
3 500	78 9	0 195	2 50
4 000	79 5	0 199	2 55

Though the curvature is more pronounced for the dioxide the greater change in surface area occurs with the trioxide

One of the advantages of krypton adsorption in determining surface areas is the possibility of using relatively small volumes of adsorbent so that the development of significant temperature differences between absorbent and refrigerant will not be favoured Such differences in temperature are, however, a possible source of error which should be considered, and they may explain some of the curved B E T plots which have been reported In particular, they may be significant where very low specific surfaces are being measured and where, as a result, it is necessary to use a large volume of adsorbent

CRYSTALLOGRAPHY

Hydrogen Bonding in Calcium Orthophosphates

RECENT discussion[1,2] about the general formula of synthetic hydroxyapatites deficient in calcium has involved the nature of hydrogen bonding not only in the low calcium/phosphorus ratio defect apatites themselves but also in related stoichiometric calcium orthophosphates In particular, the relationship between OH stretching frequency and the length of the oxygen–oxygen bridge connecting orthophosphate groups has been considered The assignment by Stutman, Posner, and Lippincott[1] of the infra-red absorption band at 3,400 cm^{-1} in synthetic phosphocalcic apatites to O–H O stretching between hydrogen-bonded phosphate groups has been disputed by Winand and Dallemagne[2], who attribute this band to adsorbed water We have recently re-examined three calcium orthophosphates crystallographically and from the P–O lengths and O O separations have attempted to infer which oxygen atoms carry hydrogen atoms These more detailed results point to some difficulties in the interpretation made by Stutman *et al* [1], for example in their Table 2, which includes a comparison of a single O O distance (derived from infra-red data) with unit-cell X-ray data for various orthophosphates

In dicalcium *bis*(dihydrogen phosphate) monohydrate[3], $Ca(H_2PO_4)_2\ H_2O$, we find that the distances between oxygens in phosphate groups which we believe to be hydrogen-bonded cover the range from 2 48 ± 0 03 Å to 2 87 ± 0 05 Å with infra-red peaks at 2,320, 2,430, 2,670, 2,920, 3,160, and 3,450 cm^{-1} In monetite[3], $CaHPO_4$, the range of distances is from 2 44 ± 0 03 to 2 66 ± 0 02 Å with infra-red peaks at 2,400, 2,780 and 3,010 cm^{-1} In each structure one hydrogen bond, O_7 $O_{7'}$, in monetite and O_3 O_5 in dicalcium *bis*(dihydrogen phosphate) monohydrate, is short enough to be symmetrical For brushite[4], $CaHPO_4\ 2H_2O$, which has infra-red peaks at 2,350 and 2,900 cm^{-1}, as well as doublets ascribed to adsorbed water[5] at around 3,200 and 3,500 cm^{-1}, the distances are uncertain as the crystal structure has a lower symmetry than had been assumed in the original X-ray analysis[6] (Indeed, our experience with monetite suggests that further X-ray data would be inadequate to locate the hydrogen atoms, for which neutron diffraction, preferably at low temperatures, would be required) In the crystal structures of monetite and dicalcium *bis*(dihydrogen phosphate) monohydrate there are two phosphate groups in the asymmetric unit of the crystallographic cell and the O–H O bonds are expected to be roughly linear Since the O O distances in these structures spread over several tenths of an Ångstrom and some of the distances are, we consider, only partly occupied by hydrogen atoms, and since each structure exhibits a range of frequencies, some probably the result of combinations[7], it would be a simplification to expect one O–H frequency to typify each structure It does not seem advisable, therefore, in these orthophosphates to correlate a representative frequency with one O O distance or with Ca/P ratio Although the mean volume occupied per phosphate group would appear to decrease slightly with increasing acidity, in accordance with Table 2 of reference 1, the shortest O O distance obtained from the X-ray refinements did not alter significantly when the Ca/P ratio was changed from 1 0 to 0 5

If hydrogen bonding within a phosphate group is rejected as we have suggested in brushite[8], the shortest interphosphate O O distance of 2 9 Å in hydroxyapatite itself, given by Stutman *et al* [1] from a recent refinement[9] of the crystal structure in space-group $P\,6_3/m$, is larger than the 2 50–2 60 Å generally found between fully hydrogen-bonded phosphate groups in a range of both organic[10] and inorganic[11] hydrogen phosphates In brushite, an unusually close apparent O O distance of 2 63 Å without a hydrogen bond has been attributed[4] to a reduction in crystal symmetry In monetite and calcium *bis*(dihydrogen phosphate) monohydrate, rather long interphosphate distances of 2 66 and 2 67 Å respectively have been explained[3] on the basis that they are not always occupied by hydrogen atoms, that is, the structural framework of the heavier atoms is sufficiently flexible to enable hydrogen atoms to occupy different sites It is possible that one or other of these factors may help to resolve the apparent inconsistency between the X-ray diffraction patterns of defect hydroxyapatites and some of the infra-red measurements reported

Velocity of Twin Propagation in Crystals

It is generally believed that twin lamellæ in deformed crystals propagate rapidly, but direct measurements of this velocity do not appear to have been made Recent experiments on calcite (rhombohedral calcium carbonate) have shown that, in this material, twins may propagate with the modest speed of about 2 m/sec

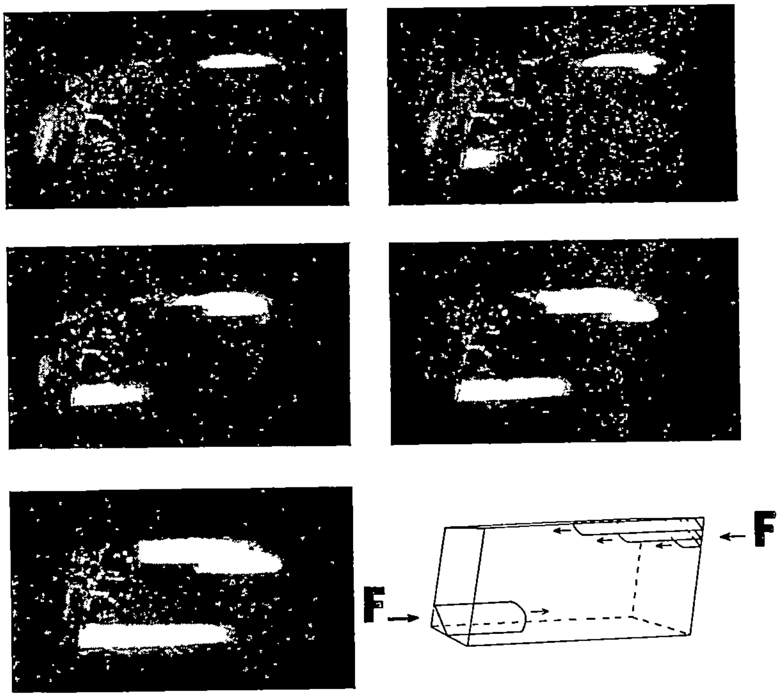

Fig 1 A series of high-speed photographs of twins propagating across a stressed calcite rhomb Interval between frames 0 6 msec, exposure time 0 05 msec

High-speed photographic methods were used to observe a cleavage rhomb of calcite to which was applied a shear stress Crossed polaroids in the optical system cause the twin lamellæ to show up as bright areas while the parent crystal remains dark (apart from surface scratches) Stopped twins—twins which have been accommodated by the lattice at elevated temperatures and stop part way across the specimen—have been etched to reveal their true extent using etching methods which detect individual dislocations[1] It is found that stopped twins extend only about 0 05 mm beyond the point at which they are too thin to be detectable by polarized light This supports the view that it is the actual propagation of the twin rather than the lateral growth which is being observed The discrepancy is of the same order as the accuracy of measurement of twin lengths from high-speed photographs and is negligible for path lengths of 6 mm or more Fig 1 shows a typical sequence of photographs, and Fig 2 shows the information which can be obtained from such observations It was not possible to investigate a wide stress range because at higher stresses a considerable amount of fracture occurred during the twinning process This diminished the path-lengths over which twins

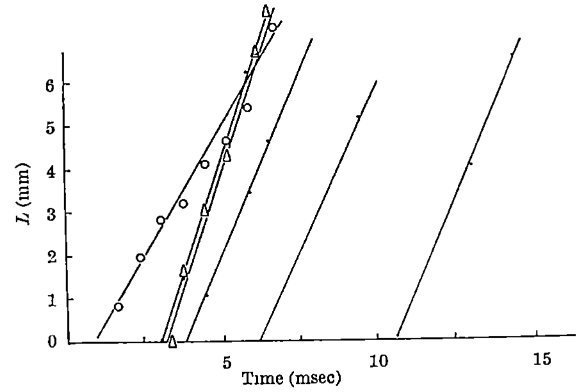

Fig 2 Measurements made from the event shown in Fig 1 The growth of six separate twins is recorded The velocity of each individual twin is reasonably constant during growth The individual velocities lie between 1 3 and 2 1 m/sec

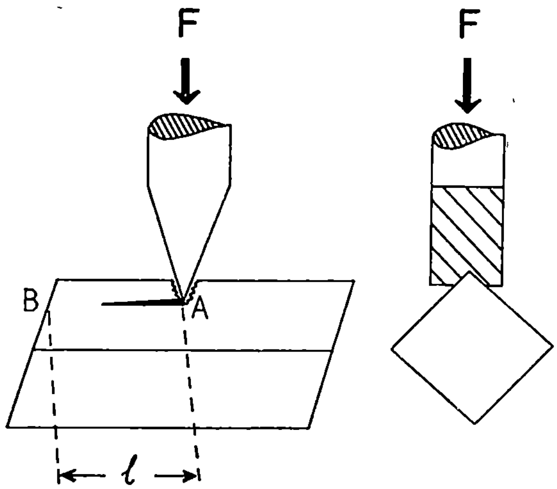

Fig. 3. Method of applying a localized transient stress used for indirect measurement of twin velocities

could be observed and reduced the accuracy of measurement. Over the range studied there was a small increase in propagation velocity with increasing shear stress.

Indirect velocity measurements were also made at various temperatures between 20° C and 340° C by applying localized stress pulses of various durations, as shown in Fig. 3. It was found experimentally[2] that if a twin starts from point *A* and, under the influence of the stress pulse *F*, reaches a length of approximately 2/3 *l*, it will become unstable and will propagate fully across the crystal to point *B* to become permanent, even if the external stress is removed during this unstable stage. If the stress is removed before the twin reaches this critical length it will retreat under the influence of unbalanced elastic stresses in the surrounding parent lattice. For a stress pulse of given duration there will therefore be a value of *l* below which a permanent twin will occur and above which no permanent twin will be formed.

Experiments were carried out to determine the critical value of *l* at various temperatures and from these values the average velocity of propagation of a twin lamella was calculated as a function of temperature in the range 20° to 340° C. The 20° C value agreed well with the value obtained by direct observation, being 2·2 (± 0·1) m/sec. The velocity of propagation increased with temperature so as to correspond to a thermally activated process with an activation energy of about 1·6 kcal/mole.

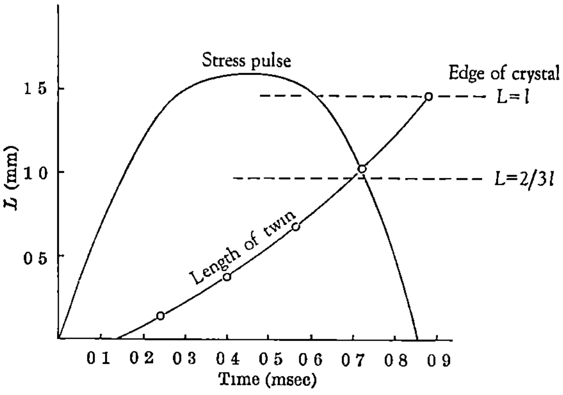

Fig. 4. A typical transient stress experiment showing length of twin lamella and stress as functions of time

High-speed photographs were taken of the twinning process under the latter experimental conditions where stress pulses were used, and Fig. 4 shows the information obtained. It is clear that the twin continues to propagate after the stress has ceased, but by this time it is more than two-thirds of the way across the specimen ($L > 2/3\, l$).

From the work of Jillson[3] it is possible to say that the velocity of propagation of twin lamellæ in zinc must be greater than about 30 m/sec when they are propagating freely. Dr. J. H. Brunton (private communication) of this laboratory has recently obtained high speed cine films of the propagation of twins in zinc and has found a range of velocities up to a maximum of about 300 m/sec. Explosive loading was used for these experiments, and the stresses and rates of strain were very high so that the maximum velocities observed are probably near the maximum possible for this material.

This velocity of twin propagation for zinc is about one-seventh of the velocity with which the shear stress would propagate in the metal. It is thus comparable with the expected maximum velocity of dislocation movement[4]. The observed velocity of twin propagation for calcite is, however, remarkably low. This may perhaps be associated with the brittle nature of the crystal.

The kinetic mechanism of the twinning process is far from clear, and further work is necessary. Such studies may give us a fuller understanding of the behaviour of crystalline materials under high rates of strain and under impact conditions.

We thank Prof. B. A. Bilby for helpful discussion.

CHEMISTRY

Failures in Stressed Nylons

Ensanian[1] has observed that concentrated hydrochloric acid alone, or a mixture of hydrochloric acid, alcohol and zinc dust, caused rapid failure of a stressed nylon strip. In this connexion the results of some work we have been doing independently should be of interest.

Several nylon mouldings had been observed to crack and delaminate when in contact with electrolyte from discharged dry cells. Investigation of a number of possible causes of this cracking has shown that aqueous zinc chloride solutions, varying in concentration from 20 to 80 per cent, are effective in producing the failures observed (Fig. 1).

Mouldings that have been suitably stress-relieved are not affected by 80 per cent zinc chloride solution. The types of failure shown in Fig. 1 *B* occur with nylon 6, nylon 66, and nylon 11 under stress, and nylon components made by different techniques such as plunger and screw pre-plasticized injection moulding or by extrusion moulding can exhibit this stress cracking.

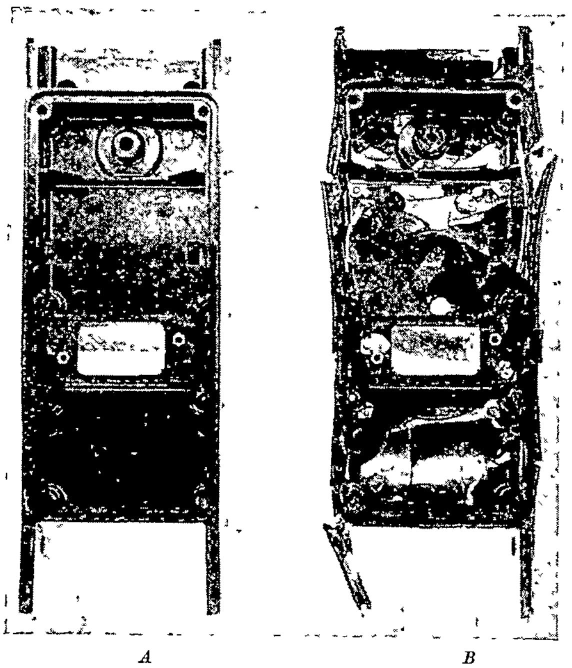

Fig 1 Nylon 6 mouldings (length, 23 cm) *A*, Untreated, *B*, treated with 80 per cent zinc chloride solution (one drop of solution at each of eight points for 24 hr at room temperature) After cracking the moulding in Fig 1 *B* had increased in length by 2 per cent

Saturated aqueous solutions of other chlorides and zinc salts have been examined and shown to be ineffective on stressed nylon mouldings These include ammonium chloride, aluminium chloride, cupric chloride, barium chloride, calcium chloride, magnesium chloride, manganese chloride, nickel chloride, ferric chloride, zinc nitrate, zinc acetate, zinc permanganate, and zinc sulphate

Zinc chloride solutions are acidic, but they are much more effective than hydrochloric acid alone or the mixture used by Ensanian[1] in causing failure The effect of single drops of 80 per cent zinc chloride solution when placed on a stressed nylon moulding is dramatic This effect is very sensitive to temperature, mouldings that crack in 3–4 hr at room temperature (20° C), crack in 30 min at 35° C and in 5 min at 50° C

When a single drop of 80 per cent zinc chloride solution is applied to a stressed nylon moulding, cracking can occur at points up to 15 cm from the drop Chemical examination of cracked areas remote from the drop shows the presence of zinc chloride This suggests that the zinc chloride moves rapidly, by capillary action, along the cracks as they grow

Results indicate that aqueous zinc chloride solutions could be used to test for the presence or absence of stresses in nylon mouldings and also for the effectiveness of any stress relieving process used on a moulded component Further work is being done to enable the most suitable test conditions to be selected

Stressed polymethyl methacrylate in contact with 80 per cent zinc chloride solution exhibits severe surface crazing before cracking and breaking The rate of attack, however, is much slower than with nylon Stressed samples of low- and high-density polyethylene, polypropylene, rigid polyvinyl chloride high-impact polystyrene and polyacrylonitrile-butadiene-styrene were not affected by 80 per cent zinc chloride solutions at 20° C

Infra-Red Extinction Coefficients for Amorphous and Crystalline Nylon

In a recent study of the NHCO group in polyamides and proteins[1] it was found that the peak extinction value of the infra-red fundamental NH absorption band at 3,300 cm^{-1} for nylon 6 depended on the mode of preparation of the specimen film under examination Films cast from dry formic acid by rapid evaporation of the acid gave lower extinction values referred to the CH absorption band than films subjected to heat annealing

It was found that these results could be explained on the assumption that the films prepared from formic acid were less crystalline than those subjected to heat treatment and that the peak molar extinction coefficient of amorphous nylon is about one-sixth that for crystalline nylon[1]

Further results have now been obtained which support this hypothesis by recording the change in peak extinction of the NH absorption band during the melting of nylon 6 A film was cast on a microscope slide and clamped between the two halves of a high-temperature cell similar to that described by Richards and Thompson[2], but with the cell windows covered by microscope cover-slips to maintain a uniform temperature The extinction-temperature relation obtained is shown in Fig 1 A sharp drop in

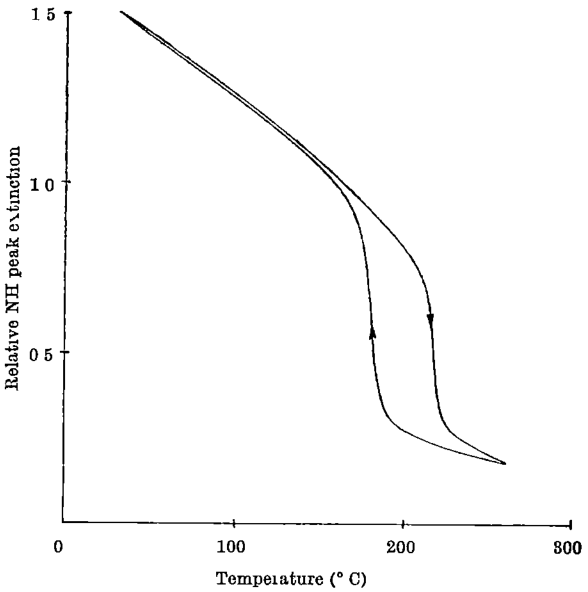

Fig 1 Change in peak extinction with temperature for the infra-red fundamental NH absorption band at 3,300 cm^{-1} for nylon 6

extinction occurs at about the melting point of nylon 6 (~ 215° C) to a value about one-third that just above the melting point Now measurements on similar samples of nylon give values of crystallinity of between 50 and 60 per cent as originally prepared, so the peak extinction of the crystalline nylon must be about five times as great as that for molten nylon at the temperature of the melting point, in rough agreement with the estimates based on crystallinity measurements[1]

A relation similar to that shown in Fig 1 has also been obtained for nylon 11, the rapid fall in extinction taking place at a lower temperature consistent with the melting point of nylon 11 (~ 185° C)

These results appear to conflict with those reported by Holliday[3] for nylon 66, who found a fall in extinction of the NH absorption band at a temperature about 50° C higher than the melting point (~ 265° C) Attempts to repeat his results failed because of the tendency of the sample to scorch even in an inert atmosphere

In conclusion, it should be mentioned that small shifts in the frequency of the NH absorption band to higher values during the melting process were recorded in agreement with Holliday's results

Reaction of CCl_2F_2 and C_2H_6 with Iron Films

THE stability of CCl_2F_2 ('Freon 12', E I du Pont de Nemours and Co trademark) at moderately high temperatures (300° C) in the presence of metals and saturated hydrocarbons is of importance because of the wide application of this substance as a refrigerating fluid A number of workers have investigated its stability Norton[1] observed the thermal decomposition of pure gaseous CCl_2F_2 to occur at a significant rate (1 per cent decomposition/h) at a temperature of about 520° C He observed that the decomposition was strongly catalysed by Fe_2O_3 but not by bulk iron Spauschus and Doderer[2] reported that at 175°–200° C, CCl_2F_2 reacts with a highly refined mineral oil to produce $CHClF_2$ ('Freon 22') and a carbonaceous residue The exact nature of this reaction is unknown, but it is influenced by the presence of bulk iron and other metals

Clean metal surfaces, such as those generated in an ultra-high vacuum or during a wear process, are often observed to be highly reactive chemically[3,4]

The interaction of CCl_2F_2 and C_2H_6 and a clean iron film was investigated The iron film was prepared by evaporating in ultra-high vacuum ($p = 5 \times 10^{-9}$ torr) a small coil of 99 99 per cent pure iron on to the surface of a 4 in diameter 'Pyrex' reaction bulb The bulb was heated to the desired temperature with a heating mantle or an oil bath The CCl_2F_2 was 99 5 per cent pure and the C_2H_6 was 99 99 per cent pure After the iron film was deposited, the gas or gas mixture was admitted to the reaction bulb At the completion of an experiment, the gases were removed from the bulb and analysed on a mass spectrometer Ultra-high vacuum procedures and measurement techniques used in these experiments are similar to those published in detail elsewhere[4]

A summary of the experimental conditions and results for the experiments performed are listed in Table 1 No gaseous decomposition products were observed when CCl_2F_2 or $CCl_2F_2 + C_2H_6$ remained in contact with an initially clean iron film at 200° C, however, some adsorption did occur At an iron film temperature of 350° C, a dose of 2 18 × 10^{18} molecules of CCl_2F_2 was completely adsorbed and a small amount of carbon monoxide appeared in the gas phase This probably was due to a reaction of an adsorbed species with the glass substrate Ten per cent of an initial dose of 1 76 × 10^{18} molecules of C_2H_6 was adsorbed on an iron film at 350° C and a small amount of H_2 appeared in the gas phase When a mixture of CCl_2F_2 and C_2H_6 was in contact with an iron film at 350° C, a small amount of H_2 and CO appeared in the gas phase, there was no evidence for the presence of $CHClF_2$

These experiments indicate that while CCl_2F_2 and C_2H_6 adsorb on a clean iron film at 200° C and 350° C, there is no conversion of CCl_2F_2 into $CHClF_2$

I thank Miss Nancy Keary for assistance with the experiments

Elasticity of Soap Films : an Amendment

IN a recent communication[1], I suggested that the Gibbs theory of surface elasticity provided a satisfactory interpretation of the experimental elasticities of films of sodium dodecyl sulphate solution which had been reported by Mysels, Cox and Skewis[2] However, Prof K J Mysels[3] has kindly pointed out that my equation 3 implies depletion of the surface-active solute by adsorption while the soap film is being formed, whereas, in fact, there is a good deal of evidence against this

It is well known, for example, that the surface tension of soap films does not change appreciably as they undergo drainage, indeed, a film could not sustain a measurable gradient of tension Secondly, the recent work of Mysels and Cox[4] has fully substantiated Frankel's equation for film thickness[5], which is based on the assumption that a soap film is drawn off the surface of the bulk solution without significant stretching, carrying unchanged substrate solution with it Thirdly, direct evidence for this model of soap films has been provided by Corkhill, Goodman, Haisman and Harrold[6], who determined the composition of draining soap films by radio-tracer methods

Consequently, a more realistic starting point for estimating the contribution of the Gibbs effect to film elasticity—in place of equation (3)—would be

$$C = 10^3 (2\Gamma_0/L_0 - 2\Gamma/L + 10^3 C_0) \qquad (3)$$

in which C_0 and Γ_0 refer to the original solution from which a film (thickness L_0) was prepared, while C and Γ apply to this film after it had been subjected to sudden, deliberate stretching Clearly, lower values of elasticity will be predicted on this basis Examples to show the order of magnitude with two initial concentrations of sodium dodecyl sulphate are given in Table 1, extensions of 10 per cent having been assumed

Table 1

Initial film thickness (L_0, μ)	Calculated Gibbs elasticity, E (dyne cm^{-1}) C_0 = 0 008 M	C_0 = 0 01 M
2	9	0 8
1	14	1 2
0 2	37	33

Mysels *et al* recorded elasticities in the range 8–20 dynes cm^{-1} for films of 0 01 M solution of thickness 0 25–2 5μ (ref 2) For the thinnest films the theoretical and experimental values might be considered in agreement, but for the thicker films the discrepancy is beyond the limits of uncertainty, especially as no significant variation of elasticity with film thickness could be noticed in the experiments The explanation of the results therefore becomes problematical

One possibility is that a small degree of stretching does occur in the formation of the film, sufficient to reduce the concentration to the critical micelle concentration, 0 008 M an excess surface tension of only 1 dyne cm^{-1} during the drawing of the film would suffice The calculated Gibbs elasticity just below the critical micelle concentration is seen to be of about the correct order of magnitude

Another possibility is that attainment of equilibrium between surface and surfactant solutions is not as rapid as is generally supposed Experimental data for sodium dodecyl sulphate solutions[7] show that the tension falls quickly during the first 30 msec, but by no means reaches equilibrium The graphs suggest that more than 0 1 sec is required Results are lacking for times in the range 0 1–1 sec for want of a suitable method of determination Consequently, the possibility cannot be excluded that the observed elasticities are partly due to the Marangoni effect Yet another possibility, as suggested by the authors, is that the surfactant was not pure enough to justify calculations appropriate to a two-component system

Unfortunately, therefore, the relevance of the Gibbs theory of elasticity in soap films must be considered still uncertain, as it has been since 1878

Reaction of Boron Trichloride with Ribonucleic Acids

THE effect of acids on ribonucleic acids (RNA) is markedly different from their effect on deoxyribonucleic acids (DNA) In the latter there is first a liberation of the purines to give apurinic acid[1], and then a slower elimination reaction to give pyrimidine-containing oligonucleotides[2] Advantage has been taken of this sequence of reactions to develop methods for the determination of the distribution of the pyrimidine nucleotides in DNA[3–5] With RNA, however, there are indications that mild acid treatment causes non-specific fission of phosphodiester linkages to give oligonucleotides[6], so that it appears that in this case the phosphodiester linkages are more acid-labile than the purine glycosidic linkages This can be attributed to the participation of the 2′-hydroxyl group in the formation of a cyclic intermediate with the phosphate group We have studied the action of various acid reagents, that is, hydrochloric acid under a variety of conditions, diphenylamine and 67 per cent formic acid[5], diphenylamine and absolute formic acid, methanolic hydrogen chloride, orthophosphoric acid, and polymetaphosphoric acid, and in all cases the phosphodiester linkages were broken either faster or at about the same rate as the purine glycosidic linkages When RNA was treated with boron trichloride, however, a difference was found, and this was studied in detail

The insoluble nature of RNA and its cetyltrimethylammonium salt in solvents which were not attacked by boron trichloride necessitated the reactions being carried out in suspension After the reaction the boron trichloride was removed by evaporation, the residues were dissolved in sodium bicarbonate at *p*H 7 and the solution chromatographed on Whatman No 1 paper in propan-2-ol/water/ammonia (sp gr 0 880) (35 15 3) In cases where reaction occurred, ultra-violet-absorbing components corresponding to adenine and guanine were detected and determined spectrophotometrically In addition, ultra-violet-absorbing zones were detected on the origin and as a streak from the origin to a point of R_F 0 06

The reaction of boron trichloride with yeast microsomal RNA[7] was studied at various temperatures At 12° reaction occurred with moist RNA (water content, about 15 per cent), but not with RNA which had been dried at 110° *in vacuo* In the former case, 25 per cent of the purines were liberated after 12 h No pyrimidine mononucleotides or the corresponding cyclic phos-

Table 1 REACTION OF BORON TRICHLORIDE WITH YEAST MICROSOMAL RNA

*, †, ‡, 1st, 2nd and 3rd treatments of the material indicated in the previous column

phates were detected The role of the water was obscure When dried RNA was used and extra water added, either directly or as wet methylene dichloride, the RNA was degraded to give pyrimidine mononucleotides All reactions at higher temperatures, therefore, were carried out with dried RNA as follows

Freeze-dried yeast microsomal RNA (sodium salt, 100 mg) was dried at 110° for 3 h *in vacuo* and heated in a sealed tube with boron trichloride (2 ml) The boron trichloride was removed by distillation and the residue dissolved in sodium bicarbonate at *p*H 7 and freeze dried In some cases the freeze-dried material was again dried at 110° and resubmitted to treatment with boron trichloride The extent of the reaction was estimated as described here

The results (Table 1) showed that complete liberation of the purines was achieved at 110° in 12 h When the 2′-(3′)-phosphates of cytidine, uridine, adenosine, and guanosine were treated similarly, no reaction was detected with the pyrimidine nucleotides, but the purine nucleotides gave the free base and there was considerable charring of the material

The product from the reaction with RNA at 110° was dissolved at *p*H 7 and fractionated on a column (20 cm × 2 cm^2) of 'Dowex-1-chloride' (2 per cent cross-linked, 200–400 mesh), elution being carried out with dilute hydrochloric acid (0 001–0 01 N) and then with 0 01 N hydrochloric acid containing lithium chloride (0 025–0 2 N) In addition to adenine and guanine about 24 ultra-violet-absorbing components were eluted The total ultra-violet absorption corresponded to 92 per cent of that of the original RNA, but, as some of this was due to the absorption of brown material which had been produced by the reaction, it was concluded that some pyrimidine residues had been destroyed Two major components (*A* and *B*) which were eluted with 0 01 N hydrochloric acid containing 0 1 N lithium chloride were subjected to paper chromatography in propan-2-ol/10 N hydrochloric acid/water (39 11 10) Each gave three components with one (*A′* and *B′*, each of R_F 0 97) predominating Both *A′* and *B′* had R_F 0 41 in propan-2-ol/water/ammonia (sp gr 0 880) (35 15 3) and on paper electrophoresis at *p*H 3 5 they migrated 1 5 times the distance of uridine-2′(3′)-phosphate They both had ultra-violet absorption spectra characteristic of uridine (λ_{max} 260 mμ) except that *B′* had a somewhat higher absorption at 220 mμ This was probably due to impurities eluted from the paper There were present 1 87 and 2 02 g atoms of phosphorus per mole of uridine in *A′* and *B′* respectively It appeared, therefore, that they were isomeric uridine diphosphates In a reaction carried out at 130°, decompositions of the pyrimidines was considerable and many of the fractions eluted from the 'Dowex-1' column contained non-pyrimidine and non-purine nitrogen The only pyrimidine-containing component which could be identified with certainty in this case was a cytidine monophosphate

These results show that the action of boron trichloride on RNA is first to liberate the purines and then to cause fission of the phosphodiester linkages It seems probable that the reason for the difference between this reaction and that of dilute hydrochloric or formic acids is that the boron trichloride initially combines with the 2′-hydroxyl groups of the RNA, so preventing the formation of a cyclic phosphate intermediate and subsequent breakage of the internucleotide phosphodiester linkages In support of this it was noted that after removal of the boron trichloride *in vacuo* at the end of the reaction, the dry product had a weight which was 24 per cent greater than the original RNA, and that it dissolved in water to give a strongly acid solution Further action of the boron trichloride or the acid produced in the reaction would result in the liberation of the purines, and then the phosphodiester linkages would be broken by an elimination reaction, similar to that which occurs in the case of the acid degradation of DNA[2] This would explain the formation of the uridine diphosphates In the case of RNA two isomers, namely, uridine-3′,5′-diphosphate and uridine-2′,5′-diphosphate, might arise due to the treatment with acid on the ion exchange columns

So far the extreme conditions which were necessary to effect complete liberation of the purines have resulted in some degradation of the pyrimidines to non-ultra-violet-absorbing nitrogenous groups and also to the formation of pyrimidine mononucleotides The latter may have arisen by non-specific degradation of interpyrimidine nucleotide linkages or to removal of a phosphate group from pyrimidine nucleoside diphosphates It may be possible, by repeatedly treating the RNA with boron trichloride at lower temperatures, to eliminate these non-specific effects and to obtain pyrimidine oligo-nucleotides

RADIATION CHEMISTRY

Effects of Ionizing Radiation and Peroxides on Hæmocyanin

IT has been postulated[1] that part of the radiobiological action of ionizing radiation involves an attack on the copper component of 4-electron transfer oxidases Accordingly, we utilized as a mode the oxygen-carrying protein hæmocyanin[2,3], which contains copper as the 'active centre'

From previous irradiation studies on hæmocyanin it was concluded that doses of about 200,000–600,000 r were required to modify the electrophoretic pattern or rupture the copper-protein bond[4-6] A more sensitive criterion of radiation damage is the ability of hæmocyanin to combine reversibly with molecular oxygen From measurements of the optical absorption peak at 340 mμ, which disappears on deoxygenation or destruction of the oxygen-carrying ability, Felsenfeld[7,8] demonstrated that one equivalent of peroxide per mole of copper is sufficient to destroy most of the function of hæmocyanin by oxidizing the cuprous ion of deoxygenated hæmocyanin to the cupric state

In our experiments hæmocyanin was used as it exists naturally in the serum from the horse-shoe crab, *Limulus polyphemus* The serum was obtained and processed in the manner described by Redfield[9] Dilutions of the hæmolymph were made with a 0 05 M potassium dihydrogen phosphate buffer, $pH = 7\ 0$ The radiation source was cobalt-60 γ-rays delivered at a dose-rate of 1,000 r /min (1 r = 0 91 rad) The solutions were irradiated at room temperature (22° C) while in 60-ml serum bottles fitted with rubber diaphragm stoppers Peroxide assays were made by the triiodide method of Ghormley[10]

Deoxygenation of the hæmocyanin solutions was accomplished by bubbling purified, oxygen-free, water-saturated helium gas through the solutions for 2 h The entry and exit of the helium was made by means of hypodermic needles inserted through the rubber stoppers The solutions were reoxygenated by a stream of water-saturated air Optical density measurements were made on solutions usually diluted 1 20 with buffer Appropriate controls were used throughout

The results of a large number of experiments are summarized here (1) When oxygenated hæmocyanin is resistant to attack by ionizing radiation, no change is observed in the optical density, even after storage for several days following doses as high as 40,000 r

(2) When solutions of *oxygenated* hæmocyanin are irradiated, *deoxygenated* and *reoxygenated*, measurable oxidation of the copper is observed (Fig 1) Measurements of the optical density of solutions of oxygenated hæmocyanin irradiated under different dilutions gives an initial yield[11] value of $G_0(\mathrm{Cu}^{++}) \simeq 2$ Thus, about 2 micromoles of cuprous copper are oxidized per 1,000 rads

(3) The action of ionizing radiation on solutions of hæmocyanin is due to the formation of hydrogen and organic peroxides, for example (*a*) Irradiation of *deoxygenated* hæmocyanin produces no peroxides, hence reoxygenation caused no change in oxygen-carrying capacity (*b*) Hæmocyanin is damaged in the same manner when the buffer is irradiated separately and added to unirradiated hæmocyanin (*c*) Addition of high-purity catalase to buffer diluted hæmocyanin solutions can prevent 80–90 per cent the damaging action of irradiation (*d*) Radiation damage to hæmocyanin decreases with time and has been found to be a function of the residual concentrations of peroxide (*e*) Direct addition of H_2O_2 or organic peroxides such as methyl ethyl ketone peroxide produces changes similar to that produced by irradiation

(4) The resistance of oxygenated hæmocyanin to irradiation is utilized to measure the life-time of the radiation-produced peroxides and radicals When undiluted hæmolymph is irradiated with 40,000 r the absorption peak decreases with a half-time of 24 h, but irradiation of a 1 20 dilution gives a half-time of 70 h The catalase-like action of hæmocyanin[12] makes it possible to distinguish the 'after-effects' caused by organic peroxides resistant to catalase relative to those caused by hydrogen peroxide

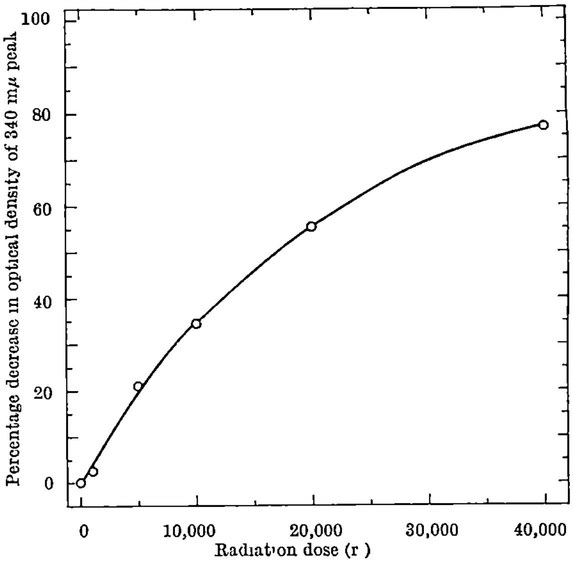

Fig 1 Effect of cobalt-60 γ-radiation on hæmocyanin The hæmocyanin was present in its natural state in the serum from *Limulus polyphemus* The serum, after dilution 1 20 with KH_2PO_4 buffer, 0 05 M, $pH = 7\ 0$, had a copper concentration of 8 55 × 10^{-5} M

This work, which will be described in more detail elsewhere, was performed under the auspices of the U S Atomic Energy Commission

BIOCHEMISTRY

Separation of Free Iodides from Iodotyrosines of Serum and Thyroidal Extracts by Means of Modified Charcoal

Blau's modification[1] of the Leland and Foster[2] method for separation of free iodides and iodotyrosines from thyroxine in *n*-butanol extracts has constituted the cornerstone of blood butanol-extractable iodine methods[3,4] and facilitates the quantitative analysis of thyroxine in thyroid extracts[1] The complete fractionation of iodinated compounds, however, requires the use of lengthy techniques of column or paper chromatography, the latter is not always easy to quantitate and is subject to considerable experimental error Block *et al* [6] indicated that activated charcoal can quantitatively separate iodinated amino-acids from inorganic iodide, but fortunately no experimental details were given We consequently worked out a method whereby Blau's alkaline reagent, containing iodide and iodotyrosines washed out of butanol extracts, is treated with modified charcoal to quantitatively adsorb the iodotyrosines and thus separate them from free iodide The method is simple and is applicable to both chemical as well as to radioisotope studies

Activated charcoal (E Merck A G Darmstadt) was de-activated with purified stearic acid as described by Synge and Tiselius[7] Two gm of stearic acid were dissolved in 200 ml absolute ethyl alcohol and added to 50 gm of activated charcoal in a 2-l flask After standing for 1 hr with vigorous shaking every few minutes, the deactivated charcoal was washed 10 times with 2-l portions of distilled water, and dried over sulphuric acid in a vacuum desiccator Five grams of dried deactivated charcoal were treated with 1 gm of DL-tyrosine dissolved in 40 ml of Blau's alkaline reagent (4 N sodium hydroxide in 5 per cent sodium carbonate), the mixture was thoroughly shaken and allowed to stand for 1 hr This constituted the 'charcoal reagent'

Standard solutions containing iodine-131 labelled free iodide, 3-monoiodotyrosine (MIT), 3,5-diiodotyrosine (DIT), 3,5,5′-triiodothyronine (T_3) and thyroxine (T_4) in 0 02 N sodium hydroxide were prepared with final concentration of 1 µgm /µl and specific activities of 1 µgm /mgm (All labelled substances were obtained from Abbott Laboratories, Oak Ridge) Samples of 0 1 ml of each of these solutions were dissolved in various solvents and treated with charcoal The solutions were centrifuged, the supernatants decanted, and the radioactivity of each charcoal sample counted in a deep-well scintillation counter Only in strongly alkaline aqueous solutions could we effect a quantitative adsorption of the iodinated amino-acids with no adsorption of free iodide By two treatments of Blau's alkaline reagent with deactivated charcoal, about 98 per cent of the iodotyrosines and only 2–3 per cent of free iodide were adsorbed

The iodotyrosines were held tenaciously by the charcoal Stearic-acid-deactivated-charcoal was therefore treated with DL-tyrosine as described here No change in the adsorbing capacity of the modified charcoal was noticed On the other hand, the iodotyrosines could be eluted from the charcoal with three washings of 10 ml 0 05 N NaOH After the addition of NaOH, the tubes were thoroughly shaken and following centrifugation the supernatant-eluent was poured off In this way, up to 98 per cent of the adsorbed iodotyrosines were eluted from the stearic acid-deactivated and DL-tyrosine-treated charcoal

Rats were injected with 25 µc of carrier free sodium iodide-131 per rat intraperitoneally At 42 hr after injection, total blood was collected from the abdominal aorta through polythene cannulas under ether anæsthesia The thyroid glands were removed, the two lobes separated and each placed immediately in a tube containing 4 N sodium hydroxide The tubes were partially evacuated of air, flame sealed and incubated at 110° C for 6 hr At the end of the hydrolysis, the digests were cooled and transferred to extraction tubes, the hydrolysis tubes were washed 4 times with 0·5 ml portions of water After neutralizing with 10 per cent v/v sulphuric acid using neutral red as an indicator, 0 2 ml acid was added in excess and the digests extracted three times with 5 ml n-butanol The combined extracts were made up to 25 ml in a volumetric flask with n-butanol Up to 96 per cent of the total thyroidal activity was thus extracted Five-ml aliquots of the n-butanol extracts were washed three times with equal volumes of Blau's alkaline reagent[4] Great care was taken to eliminate any traces of butanol from the aqueous layer The washings were combined in a 25-ml volumetric flask, made up to volume with alkaline reagent Two-ml aliquots diluted to 10-ml with alkaline reagent were treated in centrifuge tubes with 12 drops of well-mixed freshly prepared 'charcoal reagent' After centrifugation, the supernatants were decanted into another set of test tubes and were again treated with the charcoal reagent Where necessary, this treatment was repeated one or more times until no more countable activity was found in the charcoal Usually two such treatments were adequate, unless traces of butanol were carried over with the alkaline reagent The various fractions were counted in a deep-well scintillation counter When standard solutions added to 1 ml of 4 N sodium hydroxide, hydrolysed for 12 hr and then analysed under the same conditions as the thyroid extracts, free iodide was produced as follows MIT, 7 3, DIT, 6 6, T_3, 9 0 and T_4, 14 5 percentage of total organic activity in each original sample This would indicate that the largest fraction of free iodide produced during the hydrolysis came from the iodothyronines

Table 1 RADIOACTIVE IODINE DISTRIBUTION IN VARIOUS FRACTIONS OF n-BUTANOL EXTRACTS OF RAT SERUM IN PERCENTAGE OF TOTAL ACTIVITY

Rat No	Thyroid uptake (percentage dose)	Percentage of dose/l of serum	Iodo-thyronines	Free iodide	Iodo-tyrosines
1	6 1	21 1	37 2	62 8	0 0
2	5 4	17 9	38 1	61 9	0 0
3	5 3	20 9	35 5	64 5	0 0
4	4 6	28 6	38 4	61 6	0 0
5	3 9	13 7	35 7	64 3	0 0
6	5 1	17 0	20 0	80 0	0 0

Serum studies in normal rats at 42 hr after iodine-131 injections are represented in Table 1 In these investigations 1 ml of serum was extracted with 5 2 and 2 ml n-butanol respectively after acidifying with 0 2 ml of 10 per cent v/v sulphuric acid The butanol extracts were combined and made up to a total volume of 10 ml, 5 ml of which was washed three times with equal volume of Blau's reagent[4] The alkali wash was treated with charcoal as above No traces of iodotyrosines were found in the alkaline wash of the normal rats' serum extracts, in line with findings of other workers[5,9]

The alkaline hydrolysis of thyroid glands of 8 normal rats yielded the following results iodothyronines 25 3 ± 2 9 per cent, iodotyrosines 68 6 ± 2 7 per cent, free iodide 5 6 ± 0 9 per cent of total activity of the thyroid extracts which are in fair agreement with literature values[8–10] The low values for free iodide concur with the view that the unhydrolysed thyroid contains not more than traces of iodide in the free form[10,11] Our values for iodothyronines exceed those usually reported in the literature During enzymatic hydrolysis iodothyronines are deiodinated[9] to a larger extent than by the hydrolysis used here Some deiodination also takes place during paper chromatography, where as much as 15 per cent of total activity is often encountered at the origin, indicating incomplete enzymatic hydrolysis

The development of methods for chemical analysis of the various fractions separated by the present technique are now in progress

We thank Dr Karl Gaede of the Instituto Venezolano de Investigaciones Científicas, for supplying us with the radioisotopes used in this work

Free Amino-acids of Isolated Calf Thymus Nuclei

CALF thymus nuclei prepared by the sucrose–calcium chloride method of Allfrey *et al* [1] are remarkably biochemically active, as judged by the incorporation of labelled amino-acids into the nuclear proteins[1,2] Such nuclei apparently lose little nuclear material during the process of isolation since they still retain their acid-soluble nucleotides[3] Furthermore, as will be shown in this communication, the sucrose–calcium chloride nuclei also contain a free amino-acid pool which can be released by ethanol extraction of the nuclei

During the course of examining the soluble proteins of the isolated thymus nuclei[2], it was observed that the total protein and nucleic acid could not account for the total nitrogen content of the whole saline extract Either 10 per cent trichloroacetic acid or 70 per cent ethanol precipitation of the saline extract gave only partial nitrogen recovery and the acid or alcohol supernatant was found to be ninhydrin-positive Direct alcohol extraction of the whole nuclei gave an intensity of ninhydrin colour comparable to that of the alcohol supernatant made from the saline extract It appeared obvious that the thymus nuclei prepared by the sucrose–calcium chloride method retained their free amino-acids, which can be recovered from the saline extract Two-dimensional paper chromatography of such an alcohol extract was carried out, utilizing the phenol–lutidine solvent system[4], and showed, among some unidentified peptides, the following constituents alanine, β-alanine, arginine, aspartic acid, cystine (as cysteic acid), glutamic acid, glutamine, glutathione, glycine, histidine, leucine and isoleucine, lysine, methionine (as methionine sulphone), phenylalanine, proline, serine, taurine, threonine, tyrosine, and valine Of these, the glutamic acid spot was the most intense Other amino-acids found in relatively significant concentration were serine, glycine, aspartic acid, lysine, threonine and taurine

Because of the great difference in concentration among the amino-acids, they were examined quantitatively by column chromatography using a Spinco model 120 amino-acid analyser, the results of which are shown in Table 1 It may be noted that the total amino-acid content is quite low when estimated on the basis of total nitrogen content of the ethanol supernatant This is because only part of the free amino-acids are included in the quantitative analysis, and the presence of small peptides is excluded Moreover, not all the nitrogen of the alcohol supernatant is due to amino-acids Osawa *et al* [3] have reported that more than 80 per cent of ultra-violet light absorbing material present in the acid-soluble fraction of the calf thymus nuclei is due to free nucleotides The present result, showing that only a small portion of the ethanol extract is due to amino-acids, thus indirectly confirms their findings

Table 1 FREE AMINO-ACIDS OF CALF THYMUS NUCLEI

Amino-acid	% of total nitrogen of ethanol supernatant	Relative weight ratio (glutamic acid = 100)
Alanine	0 54	2 3
Arginine	0 80	12 5
Aspartic acid	1 3	3 3
Cystine	0 29	4 5
Glutamic acid	8 5	—
Glycine	2 6	7 9
Histidine	0 21	0 91
Leucine	0 16	1 5
Isoleucine	0 07	0 65
Lysine	1 3	7 5
Methionine	0 05	0 59
Phenylalanine	0 06	0 89
Proline	0 48	3 4
Serine	2 1	12 6
Threonine	1 1	0 84
Tyrosine	0 06	1 1
Valine	0 15	1 1
Total	19 77	

The characteristic feature in the pattern of the free amino-acids of the isolated thymus nuclei is the high concentrations of taurine and glutamic acid High level of taurine in extracts of normal and neoplastic mouse tissues has also been reported by Roberts and Frankel[4], although the significance of its presence is unknown The high concentration of glutamic acid in the nuclear extract seems to be a common feature among many tissue extracts[4-6]. Apart from the predominance of glutamic acid and taurine, however, the quantitative pattern of free amino-acids of the thymus nuclei is different from that of other normal tissues, such as muscle, liver and epidermis[4], and appears to be, as pointed out by Roberts and Frankel[4], characteristic of the particular tissue used

The free amino-acids of the calf thymus cell nuclei seem to contain almost all the protein-bound amino-acids However, the relative concentrations of the individual amino-acids show little relationship to the amino-acid composition of calf thymus nuclear proteins[5,7] The significance of the nuclear free amino-acids cannot yet be assessed from the present quantitative estimation

Sub-cellular Distribution of 5-Hydroxytryptamine in Guinea Pig Brain

Inouye, Kataoka and Shinagawa[1] have recently criticized, by implication, my work on the sub-cellular distribution of 5-hydroxytryptamine (HT) in guinea pig brain[2] I do not agree that my assays were significantly interfered with by substance *P* The reasons for this are as follows

(1) The rat fundus strip was found to be relatively insensitive to substance *P* (1 μg HT was equivalent to 2,500, instead of 570 U substance *P*) and the response was qualitatively different substance *P* gave a rapid contraction followed by a fall in tonus during the 30-sec period of application of the drug, while HT gave a slower contraction which was not complete in 30 sec (cf Vane[3]) The contraction produced by the brain extracts resembled that of HT More recent work by Miss J Cleugh[4] shows that homogenates of the whole brain of guinea pigs contain 50–100 U substance *P*/g tissue when assayed on the fowl rectal cæcum[5] in the presence of blocking agents for HT and other interfering substances The HT content of my guinea pig brain homogenates was 442 ± 187 ng/g in 11 experiments This compares with Correale's[6] figures of 200–500 ng/g for guinea pig brain Amin, Crawford and Gaddum's figures[7], referred to by Inouye *et al*, are here irrelevant, being for the dog

Thus, taking the best and worst situations (lowest substance *P* content with highest HT content, and vice versa) 3–16 per cent of my total HT activity might theoretically have been due to substance *P* In practice, in the doses used for assay, the amount of substance *P* present would have been below threshold

(2) Although HT was usually assayed on brain preparations heated at 100° and *p*H 4 for 10 min to release bound HT, the results were checked against the acetone extraction procedure of Baker[8] modified from that of Amin *et al*[7] The results agreed with the simpler acid extraction method within the error of the assay method

(3) The HT contents of the brain homogenate and fractions were very low when prepared from animals pre-treated with reserpine

(4) Baker[9], using the rat fundus strip, found essentially the same distribution of HT in brain fractions as I did, this is in contrast to her own earlier results with duodenum[10] Michaelson and I[11] have checked the earlier results using the spectrofluorophotometric method and have obtained essentially the same results, with, however, less variation from one experiment to another We found the same distribution in untreated animals and animals treated with iproniazid, a monamine-oxidase inhibitor, in the latter, the absolute concentration of HT in the various fractions, including the nerve-ending fraction, was, as would be expected, more than twice as high as that in the untreated animals A detailed account of this work is in preparation Potter and Axelrod[12] have confirmed the localization of hydroxytryptamine in the presynaptic-vesicle-containing nerve-ending fraction[13] using the fluorophotometric method

Regarding the stability of endogenous and added HT, my results showed[2] that both endogenous and added HT were stable in the presence of intact brain particles but were rapidly destroyed when the preparation was treated with ether This destruction was inhibited by iproniazid (10^{-4}–10^{-3} M) The brain particle preparation in question contained some microsomes

Apart from possible species differences, it is difficult to give a rational explanation of the discrepancy between my findings and those of Inouye *et al*, however, in the light of subsequent results obtained in my laboratory and elsewhere, I do not feel inclined to modify my conclusion that HT in guinea pig brain is localized in the pre-synaptic vesicle-containing nerve-ending fraction, and that the dense type of storage particle found in duodenum does not occur in this brain

Metabolism of Rose Bengal

ROSE bengal has been used for chromo-excretion liver tests usually without a more accurate investigation of the composition of the dye From the results of Stowe *et al*[1], it appears that only highly halogenated derivatives of fluorescein are selectively excreted by the liver It is important to use a pure preparation which does not contain less-halogenated derivatives Recently, a number of authors[2-4] directed attention to the heterogeneous character of commercial preparations, but only Bocci[4] isolated pure rose bengal (tetrachlorotetraiodofluorescein) by paper chromatography and used it for investigations in metabolism Recent publications[3-5] indicate that rose bengal is not metabolized by the organism and is not transformed into other derivatives which can be detected by paper chromatography

Since it is difficult to use paper chromatography for obtaining pure substance on a large scale, we used adsorption chromatography on alumina[6] Commercial rose bengal (Geigy), dissolved in 96 per cent ethanol, was applied, and for the elution the same solvent was used, whereby a separation into ten dyes was obtained Moreover, we investigated the dye which was eluted as the second from the column It had an absorption maximum at 550 mμ, a molar extinction coefficient of 99,120 and elementary analysis corresponded to tetrachlorotetraiodofluorescein Labelling with iodine-131 as described by Liebster and Andrysek was adopted, with a 70 per cent radioactivity yield and labelled rose bengal was purified by removal of the traces of inorganic iodide iodine-131 by repeated precipitation

This preparation was administered intravenously to rats in amounts of 1–20 μc per animal In the contents of the small intestine and in liver homogenates we were unable to detect a substance which differed from that administered by paper chromatography in systems 25 per cent ethanol – 5 per cent ammonia (1 : 1) and n-butanol–ammonia–water–ethanol (100 : 44 : 1 : 20). Investigating the distribution of radioactive rose bengal in the organs, urine and fæces of rats, we found a considerable amount of radioactivity in the urine (as much as 8 per cent of the administered activity) although the urine was not coloured. The thyroid gland had also a higher activity (about 0·08 per cent of the administered activity) than the other organs (about 0·001 per cent). When the same amount of preparation was administered orally, the activity in the thyroid gland was substantially lower (about 0·015). The rats were killed 2, 4 and 6 days after administration, which did not influence the level of activity in the thyroid gland and urine. From this it appears that substantial metabolic changes occurred within 48 hr. after the administration.

From these results it appears that after the intravenous administration of rose bengal a partial loss of iodine occurs or at least an exchange of iodine-131 for inactive iodine. Probably an active metabolic process in the organism is involved as suggested by the different activities of thyroid glands, depending on the route of administration. We also can rule out a simple exchange reaction of iodine-131 for inactive iodine in the organism, as under physiological conditions (temperature 37°, pH 7) this reaction does not occur *in vitro*.

Coumarin-like Substances from Australian Termites

HÆMOLYMPH from several Australian termites of the genus *Nasutitermes* (family Termitidae) contains, in appreciable quantities, three closely allied, highly fluorescent substances of unknown metabolic function. These substances, for which the names nasutin-*A*, -*B* and -*C* are proposed, are readily detectable by means of paper chromatography. With water-saturated butanolic ammonia as mobile phase, the nasutins give yellow spots (with characteristic R_F values), fading to colourless on exposure to air, but thereupon brilliantly blue-fluorescent under ultra-violet light.

Nasutins have been detected in *Nasutitermes exitiosus* Hill, *N. fumigatus* Brauer, *N. magnus* Froggatt and *N. walkeri* Hill, but they appear to be absent from *N. dixoni* Hill and from all species of other genera (*Porotermes*, *Heterotermes*, *Hamitermes* and *Drepanotermes*) so far examined. With *N. exitiosus*, the species most thoroughly investigated so far, nasutins appear to be present at all stages of development and in all castes other than alates, but they exist in greatest quantities in mature workers and soldiers. As would be expected of components of hæmolymph, they are to be found in all major segments of the insects; they occur also in fresh fæces but are not detectable in the saliva. Recent large-scale work has resulted in the isolation of the three nasutins in crystalline condition, one of them being obtained in quantities sufficient for preliminary chemical characterization.

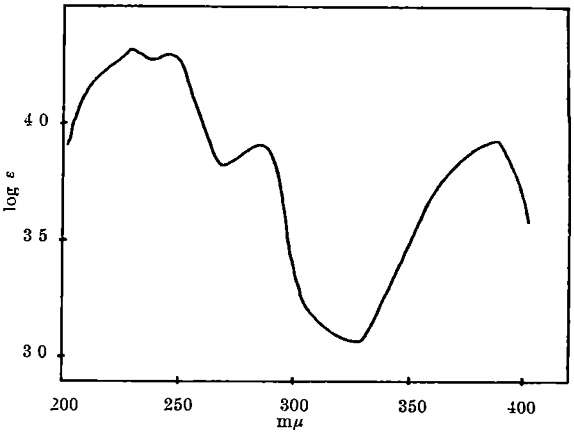

Fig. 1. Absorption spectrum of nasutin-*A* in ethanol

Nasutitermes exitiosus, the common mound-building termite of south-eastern Australia, proved to be a convenient source of nasutins. Some 15 kg of these insects were homogenized twice in methanol, the extract being separated by centrifugation and then freed from organic solvent *in vacuo*. The residual aqueous liquor was brought to pH 8·5 with ammonia, filtered, then acidified with hydrochloric acid, saturated with sodium chloride and extracted exhaustively with ether. The ethereal extract was shaken with successive portions of N aqueous ammonia until no more coloured material was removed, then discarded. The aqueous washings were acidified with hydrochloric acid and extracted exhaustively with ether. Material from the dried ethereal extract was triturated with methanol and allowed to stand. The dark brown solid (1·4 g) which separated was collected, dried, and extracted to exhaustion with acetone in a Soxhlet apparatus. Evaporation of the acetone extract left the crude nasutins as a light brown powder (660 mg). This material was recrystallized twice from large volumes of acetone to give 350 mg of pure nasutin-*A*. A portion of the material from the mother-liquors was resolved into its components by means of chromatography on Whatman 3*MM* paper with, as ascending mobile phase, butanol which had previously been equilibriated with 1 per cent aqueous ammonia. Three major bands, of R_F 0·04, 0·09 and 0·33, were obtained and these, when cut out and eluted separately with methanolic ammonia, afforded nasutin-*C*, -*A* and -*B*, respectively. Nasutin-*A* formed yellow platelets which sublimed without melting at about 300°; nasutin-*B* formed nearly colourless sheaves, melting-point 298°; and nasutin-*C*, colourless needles of undetermined melting-point.

According to analytical figures obtained from the free substance and from its dimethyl- and diacetylderivatives, nasutin-*A* has the constitution $C_{16}H_8O_7$, with no alkoxyl group present The ultra-violet absorption spectrum of the nasutin in ethanol (Fig 1) reveals the existence of an extended chromophore and the infra-red spectrum (potassium bromide disk) shows peaks at 3,300 and 3,290 cm^{-1} (2 × phenolic OH), 3,076 cm^{-1} (aromatic CH), 1,735 and 1,705 cm^{-1} (2 × αβ-unsaturated ester or lactone) Nasutin-*A* dissolves in mild alkali (*p*H 8 5) to form a deep yellow solution from which it is reprecipitated by acid With stronger alkali, however, the colour is rapidly discharged and acidification then affords the colourless nasutic acid (λ_{max} 223 and 313 mμ in ethanolic sodium hydroxide), which slowly reforms the nasutin on standing in contact with mineral acid (rapidly on being heated) Nasutin-*A* would therefore appear to have a coumarin-like structure with, probably, two phenolic groups and two lactone rings No information is yet available concerning the nature of the remaining oxygen atom

Inhibition of Antibiotic Formation by Bromthymol Blue and Other Indicators in *Streptomyces rimosus*

Antibiotic production can be altered either by the induction of stable genotypic changes through mutation of a culture or by the addition of compounds which modify the biosynthesis of the antibiotic Alikhanian *et al* [1] described the antagonistic effects of high inorganic phosphate-levels on oxytetracycline formation and the isolation of mutants which required the addition of increased phosphate for maximal antibiotic production Ševčík, Musílek and Komersová[2] examined the effect of various inhibitors of terminal oxidases on production of oxytetracycline and oxidation of glucose by washed *S rimosus* mycelia, and found that such compounds as potassium cyanide, sodium azide and quinacrine markedly inhibited synthesis of oxytetracycline Arsenite has also been found to inhibit production of chlortetracycline[3] Gadó, Horváth and Magyar[4] reported on the reversal of the inhibitory effect of iron on formation of oxytetracycline by methylene blue in *S rimosus* There is only limited information available, however, with the previously described compounds as to the specificity with which they inhibit tetracycline formation as opposed to antagonizing growth processes in general

In this communication are summarized several observations on the inhibition of antibiotic formation by a variety of indicators—compounds which have not previously been reported to inhibit biosynthesis of oxytetracycline Recently it has also been shown that DL-ethionine[5] is a potent inhibitor specifically of antibiotic synthesis in *S rimosus* without affecting cell growth

The procedures used for all shake flask fermentations, preparation of inocula, antibiotic assays and determinations of growth were similar to those previously described[6] Composition of the basal medium follows (g per l) glucose 10 0 (autoclaved separately), β-alanine 10 0, NaCl 5 0, K_2HPO_4 2 0, $MgSO_4$ $7H_2O$ 1 0, $CaCl_2$ $2H_2O$ 0 4, $(NH_4)_2HPO_4$ 0 2, $FeSO_4$ $7H_2O$ 0 02 and $ZnSO_4$ $7H_2O$ 0 01

When bromthymol blue was used as an acid-base indicator in a fermentation medium with *S rimosus* strain N R R L 2234, it was found that antibiotic formation was markedly inhibited This initial observation was confirmed and extended in further experiments Several other sulphonphthalein indicators, bromcresol green, bromphenol blue and bromcresol purple, were also tested Of these, bromcresol green was also a potent antagonist of antibiotic formation Other types of indicators found to be potent inhibitors of antibiotic production were methylene blue and phenolphthalein Phenylsulphonphthalein, triphenyltetrazolium chloride and litmus were only slightly active as inhibitors (Table 1)

Table 1 Summary of the 'Indicator-Dye Type' Chemical Compounds screened for Possible Inhibition of Antibiotic Formation with *Streptomyces rimosus*

Test compound*	Percentage inhibition of antibiotic yield	Percentage of inhibition of cell mass
Bromthymol blue	95	15
Bromcresol green	80	0
Bromphenol blue	21	3
Bromcresol purple	5	8
Methylene blue	89	33
Phenolphthalein	95	26
Phenolsulphonphthalein	17	0
Triphenyltetrazolium chloride	31	12
Litmus	15	0

* All test compounds were added at a level of 20 μgm /ml

It is difficult to explain the inhibitory activity of certain compounds in the sulphonphthalein series, namely, bromthymol blue and bromcresol green, and the inability of related analogues to decrease markedly antibiotic production When *p*K values are compared, one finds values of 7 0 for bromthymol blue, 4 7 for bromcresol green, 4 0 for bromphenol blue and 6 3 for bromcresol purple No apparent correlation appears to exist between the *p*K values and antagonistic activity

The recent work of Miller *et al* [7], in which a new co-factor, cosynthetic factor I, has been discovered in *S aureofaciens* which acts as a hydrogenating catalyst in reducing 7-chloro-5*a*(11*a*)-dehydrotetracycline to chlorotetracycline, would suggest that hydrogen acceptors such as methylene blue could interfere with reactions of this type Whereas methylene blue and triphenyltetrazolium chloride are both active hydrogen acceptors, one finds that the former compound is about three times as potent in inhibiting antibiotic formation as the latter compound on an approximately equimolar basis

These results show that bromthymol blue and several other indicators can act as highly specific inhibitors of tetracycline formation by *S rimosus* without adversely affecting growth

Isolation of Tetramethylpyrazine from Culture of *Bacillus natto*, and Biosynthetic Pathways of Tetramethylpyrazine

As has been shown in the previous communication[1], we have obtained tetramethylpyrazine from cultures of a strain of *Bacillus subtilis* and it had the characteristic smell of fermented soybean. The fermented soybean is the favourite food as 'natto' among Japanese people. The isolation of tetramethylpyrazine from 'natto' has been described[2]. Since *Bacillus natto* is a bacterium which ferments soybean to produce 'natto', we made an attempt to isolate tetramethylpyrazine from cultures of this bacterium.

After cultivating the bacterium for a few weeks in a medium containing glucose, peptone and meat extract, the whole cultures were subjected to flash evaporation. Water was evaporated out and the distillate extracted with ether. By addition of suitable amounts of picric acid to the ether extract a picrate was obtained. It was confirmed that the picrate is identical with an authentic sample of tetramethylpyrazine picrate by mixed melting points and comparisons of their infra-red spectra. This proved that *Bacillus natto* produces tetramethylpyrazine as does *Bacillus subtilis*.

The biosynthetic pathways of tetramethylpyrazine are of interest, since it was the second pyrazine to be discovered as a natural product and we supposed that the biosynthetic pathways differ somewhat from the pathways of the first-discovered pyrazine, aspergillic acid.

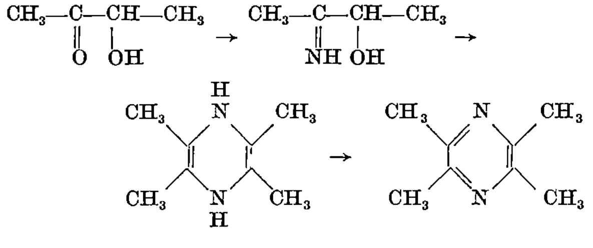
Baxter and Spring[3] have reported that aspergillic acid is biosynthesized from isoleucine via the diketopiperazine. But it is difficult to propose a plausible mechanism for the pathways from amino-acid to tetramethylpyrazine, since the hydroxy group should remain on the pyrazine nucleus instead of the methyl if it was biosynthesized from amino-acids.

In our previous communication[1], it was reported that tetramethylpyrazine was obtained after cultivation of the bacterium in media with asparagine as a source of nitrogen. The same compound was obtained when the bacillus cultivated in medias with arginine, aspartic acid, alanine, glycine, glutamic acid and even ammonium chloride, respectively, as nitrogen source.

The results might suggest that those amino-acids would be utilized as only amine parts of pyrazine and carbon parts might be converted from another source, possibly sugars.

In some micro-organisms acetoine is synthesized from sugars via pyruvic acid, and it was found by means of the Voges-Proskauer test that both *Bacillus subtilis* and *B. natto* also produced acetoine in detectable amounts.

It is thought from the chemical point of view that tetramethylpyrazine might be biosynthesized from acetoine and the amino part of amino-acids. A plausible scheme for the biosynthetic pathways is given thus:



Further proof for the mechanism is needed and we are working on this.

PHYSIOLOGY

Percutaneous Absorption of Nicotinic Acid and Ethyl Nicotinate in Human Skin

This communication concerns the vast difference in percutaneous absorption through human skin of two related substances, nicotinic acid and ethyl nicotinate.

Human skin removed surgically from breasts, legs, and arms was used within 4 h of removal. Great care was exercised in handling the specimen, and the subcutaneous fat was carefully cut away with scissors. The skin was draped over a funnel and secured with elastic bands, the corium being directed to the inside of the funnel and the epidermis to the outside. The substance to be measured was applied to the epidermis, and the funnel with the epidermis downward was placed on wooden strips in a Petri dish. When using ethyl nicotinate, because of its volatility, aluminium foil was used to cover the epidermis and the cut sides of the skin were occluded with adhesive tape. Saline was injected into the funnel so that it bathed the corium and the narrow opening of the funnel was covered. Aliquots of saline were withdrawn periodically for quantitative determinations.

Both nicotinic acid and ethyl nicotinate were labelled with carbon-14 in the carboxyl groups. The specific activity of the nicotinic acid samples was 9.2 mc./mmole and 6.8 mc./mmole, the sample of ethyl nicotinate was 6.77 mc./mmole. 0.1 c.c. nicotinic acid and 0.01 c.c. ethyl nicotinate were pipetted on to the epidermis. With nicotinic acid the excess fluid was dried off the skin surface before inverting the funnel into a Petri dish; with ethyl nicotinate the skin was covered with aluminium foil before inversion. At regular intervals an aliquot was removed from the saline bathing the corium and placed in a planchet for counting with a Nuclear-Chicago gas-flow thin-window Geiger counter. Ethyl nicotinate was converted to ethyl nicotinate hydrochloride by previously adding two drops of 1 N hydrochloric acid to the planchet. The percentage of substance recovered was determined by measuring the counts obtained in the saline bathing the corium and comparing this with the number of counts applied to the epidermal surface. In order to determine the rate of penetration of skin without epidermis, the epidermis was removed by heating the skin to 63° C on a hot plate for 2 min, after which the epidermis peels away from the corium with ease. The radioactive compounds were then applied directly to the surface of the dermis and in the same way aliquots were taken at regular intervals. Percentage penetration through skin without epidermis was thus calculated for both compounds.

Twenty-four pieces of skin from 12 different specimens were used for nicotinic acid, and 14 pieces from

Table 1 Percutaneous Absorption of Nicotinic Acid and Ethyl Nicotinate in 4 H

	Penetration of nicotinic acid			Penetration of ethyl nicotinate		
	No of observations	Range (per cent)	Average (per cent)	No of observations	Range (per cent)	Average (per cent)
Epidermis intact	24	0 0003–0 008	0 001	14	26 0–49 0	37 0
Epidermis removed	3	24 0–33 0	28 0	4	49 0–80 0	59 0

9 specimens were used for ethyl nicotinate in order to determine the penetration of human skin with epidermis intact

It is evident from Table 1 that ethyl nicotinate penetrates excised human skin at a rate 37,000 times that of nicotinic acid It is also evident that this difference in penetration is a function of the epidermis

The explanation of the remarkable difference between the penetration of ethyl nicotinate and nicotinic acid is not entirely clear Previous *in vivo* studies of penetration of these compounds through human skin revealed a large difference but not as large as that found in this *in vitro* study[1] It was shown that the absolute solubility of nicotinic acid in water and ether was less than that of ethyl nicotinate and that the water/ether partition coefficient of ethyl nicotinate was 0 136 as compared with 9 25 for nicotinic acid Although ether and water solubility may play some part in penetration[2], this work also suggests the possibility that volatility of a substance may be an important factor in the difference observed Using disappearance-rates of radioactive nicotinic acid and ethyl nicotinate from standard-size planchets, we determined that ethyl nicotinate is about 10,000 times more volatile than nicotinic acid

Relationship of Plasma Salicylate Concentration to Urinary Salicylate Excretion-Rate

A number of workers have determined the plasma salicylate-levels in man at various time intervals after oral doses of aspirin, while others have studied salicylate excretion[1-3] However, there appear to be few reports of the concurrent determination of plasma and urine salicylate after dosage with aspirin In this laboratory, the plasma salicylate concentrations and the urinary salicylate excretion-rates have been studied simultaneously in two groups of eight men who received a single oral dose of either aspirin B P or aloxiprin (The latter is the Approved Name selected by the British Pharmacopœia Commission to describe a "polymeric condensation product of aluminium oxide and aspirin")

An examination of the urinary excretion (Fig 1) shows that both aspirin B P and aloxiprin give rise to excretion-rates which are almost identical at their respective maxima, although in the case of aloxiprin the maximum is reached later It is suggested that this delay in the achievement of a comparable excretion-rate by aloxiprin can be attributed to slow absorption from the stomach This may be related to a lower rate of solution under acidic conditions, for it has been observed that the aspirin of aloxiprin dissolves more slowly than aspirin B P in buffer solutions over the range of *p*H 2–8, the difference being most marked at *p*H 2 (ref 4)

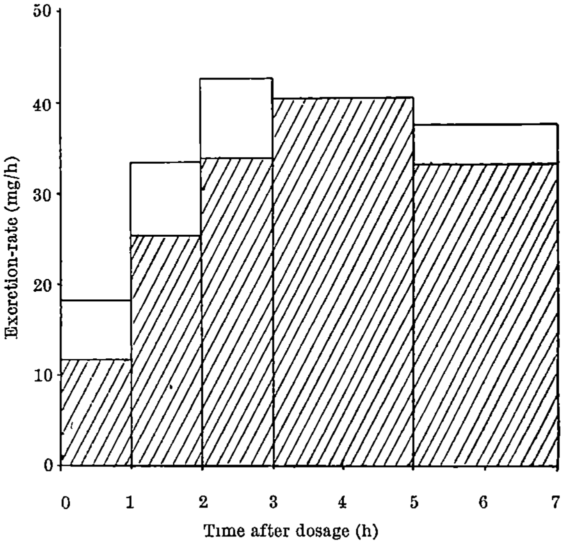

Fig 1 Mean rates of salicylate excretion in urine after aspirin B P (white), and aloxiprin (hatched)

In view of the finding that the maximum rates of salicylate excretion after aspirin and aloxiprin were very similar, it was anticipated that the maximum plasma salicylate-levels would be in approximately the same ratio This was not found to be so In fact, aspirin gave maximum plasma salicylate concentrations within the range of 3 7–6 8 mg/100 ml (mean 5 1 mg/100 ml), whereas aloxiprin gave only 2 3–3 9 mg/100 ml (mean 3 0 mg/100 ml) Also, the areas under the curves of the respective plots of plasma salicylate concentration against time seemed at first to indicate that not all the aspirin of aloxiprin was absorbed (Fig 2)

However, no appreciable difference was found between aspirin and aloxiprin with respect to the

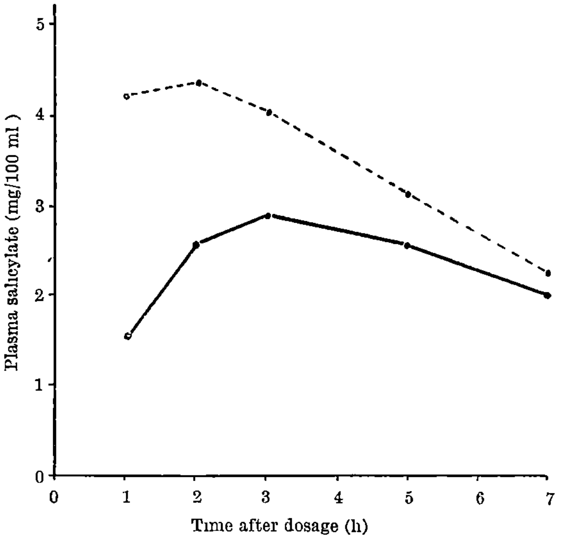

Fig 2 Mean plasma salicylate concentrations after aspirin B P , (– – –) and aloxiprin (——)

24-hour-recovery of total salicylate in the urine Also, two groups of subjects who received 1 g of aspirin or the equivalent of aloxiprin every 6 h for 36 h, excreted almost identical amounts of salicylate during a 5-h period at the end of the trial The salicylate content of aloxiprin would therefore seem to be completely available and an alternative explanation was sought for the lower blood-levels obtained

It was observed that after aspirin B P most individuals exhibited a maximum plasma salicylate at about 1 h. but the maximum rate of salicylate excretion in the urine was not attained until the third hour or later (Fig 3) Similar results are discernible in the published reports of others, but to our knowledge this fact has received no special comment

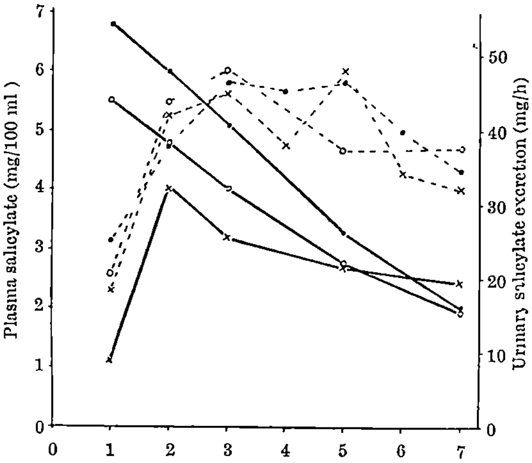

Fig 3 Examples of plasma salicylate concentrations (——) and corresponding urinary excretion-rates (- - -) in three subjects after aspirin B P

By far the greater proportion of salicylate excreted in the urine is in the form of metabolites, and it is considered that this metabolism takes place in the tissues, as distinct from the blood Thus, before being excreted, the greater part of the salicylate must pass from the blood into the tissues concerned with this metabolism The later attainment of the maximum urinary excretion rate suggests that the rate of transfer of salicylate from the blood to these tissues—and presumably to tissues generally—is lower than its rate of absorption from the gut

It is considered that after its oral administration, aspirin B P is absorbed and enters the plasma at a rate which is much faster than that at which aspirin or salicylate moves from the plasma to the tissues and therefore the serum salicylate concentration rises to a disproportionately high level The absorption from aloxiprin in the gut proceeds less rapidly, and the rates at which salicylate enters and leaves the plasma seem to be more comparable Thus the plasma and tissue salicylate concentrations always show a greater correspondence and a lower maximum plasma level is obtained

This interpretation of the experimental results implies that the relative speed of absorption of aspirin formulations cannot be accurately assessed by a comparison of the respective plasma salicylate concentrations Any difference in the relative absorption-rates will be exaggerated in that the more rapidly absorbed formulations will appear to be absorbed faster, and the less rapidly absorbed, slower, than is actually the case

The concentration of a drug in the blood is a function not only of its rate of entry but also of its rate of removal from the blood That is

$$\begin{pmatrix}\text{amount in}\\ \text{blood}\end{pmatrix} = \begin{pmatrix}\text{amount which has}\\ \text{entered blood}\end{pmatrix} - \begin{pmatrix}\text{amount which}\\ \text{has left blood}\end{pmatrix}$$

For the rate of change in the blood concentration to provide a measure of the rate of absorption of a drug, the rate of removal of the drug from the blood must either be directly proportional to its blood concentration or must have a negligible value

The experimental results presented here suggest that in the first few hours after the oral administration of a single dose of salicylate the relationship between the plasma concentration and the rate of removal of salicylate from the plasma is not always a simple proportionate one and that some other factors exercise an effect Protein-binding of the salicylate could be one such factor

Acetylcholine : a Central Transmitter?

ALTHOUGH many factors need to be considered before a chemical compound can be identified as a synaptic transmitter substance within the nervous system[1], it is essential that, when administered to the appropriate subsynaptic receptors, it evokes the same response of the particular neurones as does the synaptically released transmitter The demonstration of such a postsynaptic action is, however, insufficient by itself to warrant the assumption that an agent is a transmitter Thus the conclusion that acetylcholine is an excitatory transmitter of Renshaw cells is based not only on the excitatory action of this substance but also on the very close similarity between the pharmacology of this excitation, the pharmacology of the synaptic excitation of these neurones by volleys in motor axon collaterals and the pharmacology of the mammalian neuromuscular junction[2,3] Recently, the sensitivity of neurones in the cerebral cortex to electrophoretically administered acetylcholine[4,5] has led to the suggestion that such cells may be activated synaptically by cholinergic fibres[5] However, no details have been given of the effect of pharmacological agents on the synaptic excitation of these neurones, moreover, the reported pharmacology of the excitation by acetylcholine differs in certain respects from that of the excitation of Renshaw cells by this choline ester

This communication is concerned with the excitatory effect of acetylcholine on neurones in the ventrobasal complex of the thalamus of cats anæsthetized with sodium pentobarbital Extracellular action potentials (0 2–1 0 mV) were recorded by means of the central barrel of five-barrel micropipettes, the four outer barrels of which contained aqueous solutions of the various compounds which could be ejected electrophoretically[3] The neurones were excited synaptically by electrical stimulation of the contralateral median, ulnar, superficial radial, sural, tibial or peroneal nerves

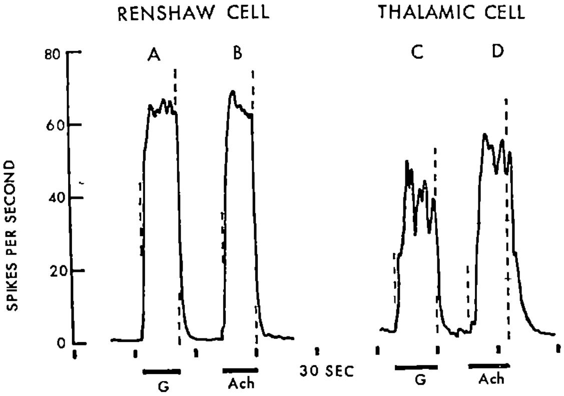

Fig 1 Frequencies of firing of a Renshaw cell (*A*, *B*) and a thalamic neurone (*C*, *D*) plotted by means of a paper recorder which was driven by a rate meter of time constant 1 sec The lower bars and vertical lines indicate the time of electrophoretic ejections of L-glutamate ion (*G*) and acetylcholine (*Ach*) using currents of 70 (*A*), 30 (*B*), 60 (*C*) and 40 (*D*) × 10^{-9} amp respectively Time, 30 sec

Almost without exception thalamic neurones were excited by acetylcholine, and this sensitivity was not restricted to spontaneously active cells In many cases, particularly when neurones were fired synaptically by an afferent volley in only one peripheral nerve, the excitation by acetylcholine was of sufficient intensity to fire the cells and the sensitivity to this ester appeared to be similar to that of Renshaw cells On the other hand, particularly with more superficially located cells which were fired synaptically by volleys in two or more afferent nerves, the excitation remained subthreshold, although electrophoretic currents of up to 150 n amp were used Nevertheless, this excitation was readily revealed as a facilitation of the excitatory action of L-glutamate ion The excitatory action of acetylcholine on both types of neurone was of delayed onset and continued for much longer after the termination of the electrophoretic current than has been observed with Renshaw cells This is illustrated in Fig 1, where the frequencies of firing of a Renshaw cell (*A*, *B*) and a thalamic neurone (*C*, *D*) are plotted with respect to time These frequencies were plotted by an ink recorder and a rate meter of time constant 1 sec Consequently, short intervals could not be indicated accurately, but were measured from simultaneously filmed records Firing was evoked by L-glutamate ion (*A*, *C*) and acetylcholine (*B*, *D*), and the times of electrophoretic ejection are indicated beneath the tracings With both neurones the times of onset and offset of the amino-acid-induced firing were less than 500 msec Acetylcholine began to fire the Renshaw cell within 500 msec of the beginning of the ejection and the firing ceased within 1 sec of its termination In contrast, there was a delay of approximately 4 sec before the thalamic neurone responded to acetylcholine (*D*) and the cell continued to fire for 16 sec after the electrophoretic current was terminated

The relative potencies of various cholinomimetics was estimated by comparing the effects of injections made with electrophoretic currents of the same intensity[6] Carbamoylcholine was more potent than acetylcholine, whereas acetylhomocholine, arecoline and nicotine were less active Prostigmine was an excitant and produced little or no prolongation of the repetitive responses evoked synaptically Dihydro-β-erythroidine, a powerful depressant of both the acetylcholine and the motor-axon collateral-synaptic activation of Renshaw cells[2,3], was without action on the synaptic responses of thalamic neurones but readily blocked the excitation produced by acetylcholine In addition, dihydro-β-erythroidine had an excitatory action, an effect which has been observed with Renshaw cells[3] D-tubocurarine affected neither synaptic nor acetylcholine-evoked responses and was a weak excitant, while gallamine and tetraethylammonium also excited the neurones Atropine and atropine-like compounds had a similar action on thalamic neurones to that which has been observed on Renshaw cells[7] The depression of the excitatory effect of acetylcholine was more powerful and prolonged than the depression of the spikes which were evoked by L-glutamate ion, but synaptically produced spikes were particularly resistant to the action of these compounds

These observations are similar to those made on lateral geniculate nucleus neurones[6] and cortical neurones[4,5], and lead to the suggestion that the receptor on thalamic neurones, with which acetylcholine and structurally related excitants interact, differs from the cholinoceptive receptor of Renshaw cells Furthermore, it is unlikely that the synaptic excitation which was examined was produced by acetylcholine It is considered that the results cannot at present be interpreted as indicating a transmitter function for acetylcholine in the ventrobasal complex of the thalamus Although this compound may indeed be a transmitter, with receptor sites which differ from those of the 'nicotinic-type' of receptor on Renshaw cells, the findings raise the alternative possibility that a compound structurally related to acetylcholine may be an important transmitter within the mammalian central nervous system

Vibrio fetus Endotoxin

Vibrio fetus is recognized to-day as an important pathogen affecting reproduction in cattle and sheep *V fetus* hypersensitivity in the bovine has not been previously reported so far as we can determine

Dennis[1] has reported the isolation of a toxic lipopolysaccharide from *V fetus* The endotoxin was reported as being toxic, pyrogenic and antigenic in rabbits and mice Winter and Dunne[2], in an antigenic analysis of *V fetus*, found that an endotoxin could be extracted from the cells that was lethal for mice. This communication concerns hypersensitivity in the bovine to an endotoxin-like substance from *V fetus*

A catalase-positive, hydrogen sulphide-positive strain of *V fetus* was grown at 37° C in broth in an atmosphere containing 85 per cent nitrogen, 10 per cent carbon dioxide, and 5 per cent oxygen[3] A broth culture and the supernatant fluid from a broth culture were inoculated intravenously into cattle

Twelve calves, aged 1–6 months, and 6 adult cows, aged 3–12 years, showed clinical symptoms of anaphylactic shock varying from mild to lethal depending on the size of the inoculum. One ml per 50 lb of body-weight of the supernatant fluid from a broth culture of *V fetus* proved lethal for two calves weighing about 300 lb. Calves were refractory to a second dose of supernatant fluid for at least 2 days after the first inoculation. The same *V fetus* supernatant fluid inoculated intradermally into cervical skin reacted positively in 36 cows, calves, and young adult cattle of a college-owned herd. The tests were read at 1–2 h after injection. These experiments, and others which will be reported later, have demonstrated a marked hypersensitivity in the bovine to *V fetus* broth culture and its supernatant fluid.

Clinical symptoms, gross pathological and histopathological changes following intravenous inoculation of *V fetus* endotoxin-like substances are very similar to those reported for other Gram-negative bacterial endotoxins.

It is suggested that the bovine becomes hypersensitive either passively during prenatal development or by contact during the early post-natal period with vibrios or other micro-organisms with antigens common to the vibrios. Abortion may be directly or indirectly associated with the hypersensitive state of the bovine to antigens of *V fetus*.

Whole-Body Skeletal Metabolic Response on Local Skin Burns

Burns, depending on their degree and extent and other complications, such as shock and infection, may lead to serious local and systemic changes in the whole body, including disorders in metabolism of water, electrolytes, proteins, etc. Some of these effects have been recorded by several authors[1,2], but still too little is known about them and about the mechanisms which control them. Practically nothing is known about the metabolic disorders in the skeleton of the burned patients. In only few reports[3–5] mention has been made of structural changes in bone seen on roentgenograms in burned patients, such as osteoporosis, periostitis, bone necrosis, osteomyelitis and periarticular calcifications and ossifications.

We are investigating these as well as other related problems connected with the influence of some physical traumatic agents (ionizing radiation, burns, frost-bite, electric shock, ultrasonic effects) on the mineral metabolism in bones. One of the numerous problems encountered during this work is that of whether the processes involved are purely local, that is, limited to the wounded area itself and the tissues immediately about it, or whether the whole skeletal system is affected.

In a previous paper[6] we published some results of experiments in which the uptake of radiocalcium in bones of rats struck by an electric current was determined quantitatively. On this occasion a generalized skeletal response on local trauma was discovered and confirmed in roentgen-irradiated bones too.

In another experiment, reported here, a local burn in white male Wistar rats weighing 120 gm was caused by putting an iron bar heated at 400° C on the right thigh. Thus, a circumscribed third degree burn of 1–2 per cent skin area arose. This procedure was carried out in 35 rats, another 35 animals serving as controls. At different intervals after beginning the experiment (4, 11, 16, 29, 42, 66 and 83 days) groups of five experimental and five control animals were formed. Each animal then received an injection of 20 μc of calcium chloride labelled with calcium-45 in 1 ml saline intraperitoneally. The rats were then killed, ether anæsthesia being used, 48 hr after injection of the isotope. Both tibiæ and scapula were cleaned. In each tibia the proximal epiphysis and metaphysis were separated from the diaphysis, and the bone samples were treated in the same way as described in our previous paper[6].

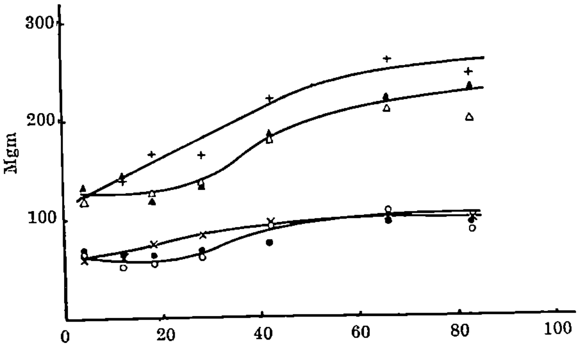

Fig 1. Weights of dry bone. Control group, ×, epiphysis, +, diaphysis, experimental group, burned leg, ○, epiphysis, △, diaphysis, unburned leg, ●, epiphysis, ▲, diaphysis

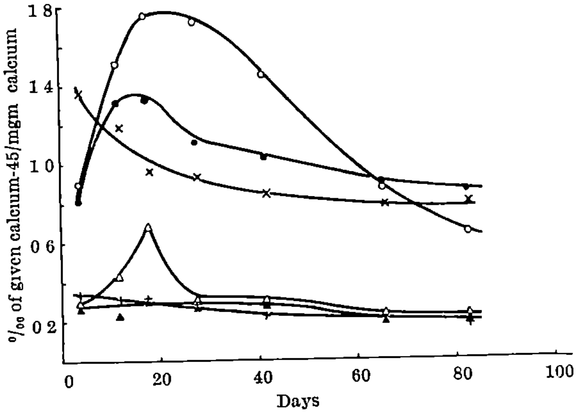

Fig 2. 48-hr accretion of calcium-45 in the tibia. Symbols same as in Fig 1

Eleven days after the injury, distinct differences appeared in the dry weight of epiphyses and diaphyses of the tibiæ on injured animals in comparison with the control group (Fig 1). The depression of weights of the epiphyses in burned animals persisted until the 42nd day and those of the diaphyses even longer, the differences being significant on the 16th and 29th day ($P < 0.05$). Analogous changes occurred also in the scapula, which is situated far from the injured place.

More distinct changes are evident when tracing the specific activity by measuring the values of two-day accretion of calcium-45 in the bones of injured and uninjured legs of the experimental animals and in the bones of the control animals Fig 2 shows that in the bones of injured animals an increased accretion of isotope at first took place, especially in the injured bones, but also in the tibia of uninjured side The calcium-45/mgm calcium in both is considerably higher than that of the tibia of intact animals ($P <$ 0 05–0 01) Again, the increase in activity was localized not only in the tibia, but was found also in the shoulder-blade, which is a bone of differently growing type Comparing both Figs 1 and 2 it is also seen that, while the weights of dry bones show a decline, the specific activity increases Even at the end of the experiment (83 days after injury) the conditions of metabolism had not become normalized, although the skin wounds were healed in most instances in about four weeks

The results of these experiments show a long-persisting and generalized metabolic skeletal response on local skin burn which was hitherto undescribed, because attempts to prove the imbalance of skeletal metabolism in burned organism, for example, by following-up the plasma calcium-levels, gave negative or uncertain results The generalized metabolic response was again proved to be a natural reaction of skeleton to local trauma The discovery of such a deep metabolic reaction to a circumscribed local burn may in future throw more light on the mechanisms involved in the forming of periarticular soft-tissue calcifications and ossifications, reported in 3 per cent of burned persons[5]

PHARMACOLOGY

Adrenergic Neurone Blocking Tropine Derivatives with Long-lasting Hypotensive Action

RECENTLY, long-lasting hypotensive agents have been described which act by blocking adrenergic neurones of these, guanethidine[1] and bretylium[2] have been widely used clinically

Among the many tropine derivatives produced in this Institute, *N* 361 (*N*-4-phenylbenzyl-3-benzoyl-σ-tropinium bromide) was found to have a strong ganglion-stimulating effect[3] When this is given in high, almost toxic, doses, however, the strong pressor effect is followed by a long-lasting fall in blood-pressure, caused by the blockage of postganglionic adrenergic neurones[4]

Because of its strong ganglion-stimulating effects *N* 361 cannot be considered for therapeutic use, but by varying the chemical structure we have attempted to obtain compounds which had the long-lasting hypotensive adrenergic neurone blocking action of *N* 361 without the ganglion stimulant and other side-effects Several compounds of this type have been examined and two of them found to be sufficiently selective in their action on the adrenergic neurones to be suitable for clinical trial They are *N* 830 (N_a-ethyl-N_b-(4-*cyclo*hexylbenzyl)-3-benzoyl-*nor*-α-tropinium bromide), and *N* 856 (*N*-(4-*cyclo*hexylbenzyl)-3-*p*-tolyl-α-tropinium bromide[5]

Both these are adrenergic neurone blocking agents which produce a long-lasting fall in blood pressure and few side-effects In cats they inhibit the contraction of the nictitating membrane in response to both pre- and post-ganglionic stimulation of the cervical sympathetic nerve They also block the contraction of the spleen in response to stimulation of the splenic nerve and in adrenalectomized animals they inhibit the pressor effects of tetramethylammonium bromide (TMA) They do not antagonize the effects of adrenaline but they produce a transient block at ganglia In this they are respectively 1 2 and 2 times as active as TMA, but the rise in pressure lasts less than 1/100 as long as the subsequent fall in pressure

In anæsthetized cats *N* 830, in a dose of 1–3 mg/kg intravenously, caused a slight and transient rise in blood pressure—not exceeding 25 mm/mercury, and lasting 20–25 sec *N* 856, in a dose of 1–1 5 mg/kg, had no immediate pressor effect on the blood-pressure but had an action similar to that of *N*-830 when the dose was increased to 2 mg/kg In this action they are significantly less active than guanethidine and bretylium

Both compounds, in doses of 1 mg/kg, intravenously, lower the blood-pressure of anæsthetized cats The effect begins within a few minutes, and from an initial level of 140–146 mm/mercury, the pressure is reduced to about 100 mm/mercury The effect increases with the size of the dose, after 2 mg/kg the pressure falls to less than 70 mm/mercury, and this fall lasts for more than 2 h In cats, both compounds block the reflex rise in blood-pressure in response to carotid occlusion for a long time and are effective in unanæsthetized as well as anæsthetized animals They are active in dogs and rats as well as in cats but higher doses must be given to produce a comparable fall in blood-pressure

In the anæsthetized cat, to produce the same reduction in the blood-pressure as 1 5–2 0 mg/kg given intravenously, it is necessary to give 3–6 mg/kg intraperitoneally 5–15 mg/kg subcutaneously, or 20–25 mg/kg into the stomach When administered by these routes, however, the drugs do not produce any apparent initial rise in blood-pressure

The compounds do not antagonize the actions of acetylcholine in the cat or, to any significant extent, in isolated rat intestine They do not affect the respiration and, in doses which lower the blood-pressure, have no action on the responses of the tibialis anterior muscle to stimulation of the sciatic nerve

A great advantage of *N* 830 and *N* 856 is that their pressor effects are so transient, lasting less than half a minute—as compared with guanethidine and bretylium, in which the pressor effects last much longer (30–120, and 2–20 min respectively) Further advantages are the rapid onset of the fall in blood-pressure and the relatively high oral absorption In cats the ratio of the oral dose to the intravenous dose producing equal effects is as low as 10 Quaternary compounds are often absorbed only very poorly from the gastro-intestinal tract and the unusually favourable absorption of *N* 830 and *N* 856 can be ascribed to their selective uptake in low concentrations by postganglionic adrenergic fibres (this has been shown in infusion experiments) and their slow rate of elimination

The compounds are relatively non-toxic, the LD_{50} in mice is greater than 20 0 mg/kg, which is larger than for guanethidine and bretylium As smaller doses are needed to produce a fall in blood pressure the therapeutic indices of *N* 830 and *N* 856 are better than those of guanethidine and bretylium

HÆMATOLOGY

Oxygen Equilibrium of Hæmoglobin A_2 and Its Variant Hæmoglobin $A_2{}^1$ (or B_2)

Evidence has been presented in a previous investigation[1] that the normally occurring minor hæmoglobin component A_2 has a considerably higher affinity for oxygen than normal Hb–A The Hb–A_2 preparations, which were isolated by carboxymethyl-cellulose (CMC) chromatography[2], however, contained relatively large quantities (up to 20 per cent) ferri–Hb or ferri–Hb derivatives In the work reported here we redetermined, therefore, the oxygen equilibria of normal Hb–A_0 and Hb–A_2, both being isolated as oxyhæmoglobin without notable oxidation to ferri-hæmoglobin derivatives The abnormal variant of Hb–A_2, known as Hb–$A_2{}^1$ or Hb–B_2 (ref 3), has also been included in this work

Blood samples from normal individuals, from thalassæmia trait carriers with increased quantities of Hb–A_2 and from heterozygous Hb–B_2 carriers containing approximately 1 per cent of the abnormal minor hæmoglobin fraction[3] were used Each blood sample was washed three or four times with isotonic saline and hæmolysed by the addition of 1 vol of deionized water and 0 5 vol of toluene per vol of packed cells The hæmolysates were dialysed at 4° C against distilled water for 12 h followed by dialysis against a 0 005 M phosphate buffer of *p*H 9 0 for 36 h The minor Hb–A_2 and Hb–B_2 were isolated by DEAE cellulose chromatography[4] 40–60 ml of the appropriate hæmolysate with a hæmoglobin concentration of about 10 gm per cent was applied to a DEAE-cellulose (Brown Co , 55 Main Street, Berlin, New Hampshire) column of 35 × 5 cm, the DEAE-cellulose being equilibrated with the same phosphate buffer as used for dialysis The elution was performed by application of a 0 005 M phosphate buffer *p*H 8 6 at a flow-rate of about 100 ml /h Hb–A_2 was eluted as a separate component in front of Hb–A, while the elution-rate of Hb–B_2 was even higher than that of Hb–A_2 The combined effluent fractions of each component and of Hb–A_0, which was eluted from the DEAE-cellulose column with the use of a 0 01 M phosphate buffer *p*H 6 0 (0 15 M sodium chloride added), were finally concentrated by CMC chromatography as described before[2] The whole isolation procedure, which lasted less than 7 h, was carried out in the cold When tested for purity by starch-gel electrophoresis[5] less than 5 per cent of Hb–A was found to be present in the Hb–A_2 fraction and less than 5 per cent of Hb–A_2 in the Hb–B_2 preparation The isolated hæmoglobin fractions were dialysed versus a large volume of distilled water at 4° C for 4 h followed by dialysis versus 0 1 M phosphate buffer of a *p*H varying from 6 8 to 7 4 at 4° for 15 h Spectral analyses of the oxygenated components were carried out with the use of the Beckman *DK*–2 spectrophotometer No notable amounts (less than 3 per cent) of ferri-hæmoglobin were detectable The hæmoglobin concentration of each fraction was finally adjusted to 1 0 gm per cent, determined by the cyanmethæmoglobin method[6]

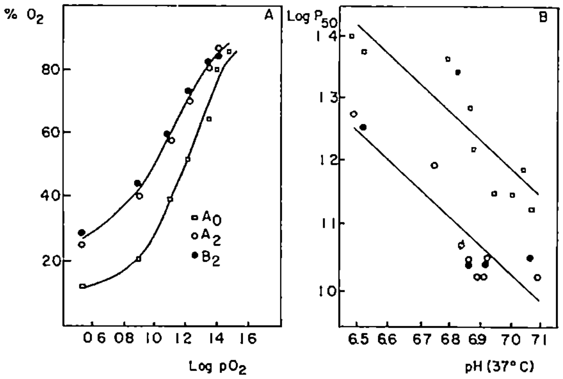

Fig 1

The procedure for the determination of the oxygen equilibria has been described previously[1] Equilibration of 1 ml samples with gas mixtures was accomplished in a tonometer of 100 ml capacity at 37° C The P_{CO_2} was maintained at a constant level of 40 mm mercury in all determinations The *p*H of an aliquot of each Hb-sample equilibrated at a P_{O_2} of 21 5 mm mercury and P_{CO_2} of 40 mm mercury was determined at 22° C using the Radiometer *PHM*4*C* model *p*H meter and finally corrected for the difference in temperature

Fig 1*A* represents examples of the oxygen dissociation curves of Hb–A_0, Hb–A_2 and Hb–B_2, the percentages of oxygen saturation were plotted against the log P_{O_2} values The relations between the changes in *p*H and the log values of the P_{O_2} producing 50 per cent oxygenation (log P_{50}) are shown in Fig 1*B* From these results the following can be concluded (*a*) Hb–A_2 and Hb–B_2 showed a substantially greater oxygen affinity than normal Hb–A_0 No difference was noted between the Hb–A_2 isolated from the blood of normal individuals and that of thalassæmia trait carriers The shapes of the oxygen equilibrium curves of Hb–A_0, Hb–A_2 and Hb–B_2 were found to be identical, the *n* values, defining the slope of the line obtained by plotting log $Y/1-Y$ (Y is the fractional oxygenation) versus log P_{O_2}, was between 1 4 and 2 0 under our experimental conditions (*b*) All three components showed identical Bohr effects (Fig 1*B*) (*c*) No notable difference in the oxygen affinities of the Hb -A_2 and Hb–B_2 fractions could be demonstrated

These investigations confirm the previously described observation of an increased oxygen affinity of Hb–A_2 as compared with normal Hb–A_0 The difference between these hæmoglobin types is located in the β-chains (Hb–A_0) and the δ-chains (Hb–A_2), these being different in more than one amino-acid residue[7,8] Elucidation of the amino-acid sequence of the δ-chain seems necessary for a better understanding of the observed difference in oxygen affinity The finding that the oxygen equilibrium of Hb–B_2, which is different from Hb–A_2 in the replacement of one unknown amino-acid residue for arginine in each δ-chain[3], is identical with that of Hb–A_2 suggests the possibility of using oxygen equilibrium experiments for demonstrating the presence of altered δ-chains in unknown minor Hb-components

Glucose-6-Phosphate Dehydrogenase Activity in the Red Blood Cells of Monkeys

In human beings there exists an inborn character of the red blood cells which is usually harmless, but which, in certain individuals, can lead to severe hæmolysis if the red cells are challenged by the ingestion of certain drugs or foods The main abnormality in these individuals is a deficiency of the enzyme glucose-6-phosphate dehydrogenase in the red cells, which usually have a correspondingly low amount of reduced glutathione in them Further, when such sensitive red cells are incubated in certain chemicals, for example, acetylphenylhydrazine, there is a marked fall in the level of reduced glutathione, which does not occur with erythrocytes of normal persons This is the glutathione stability test of Beutler[1], and it has been pointed out by Beutler *et al*[2] that the glutathione instability of the drug-sensitive cells probably results from their deficiency in glucose-6-phosphate dehydrogenase A simple test for demonstrating this enzyme deficiency state has been developed by Motulsky[3]

To find out if a similar abnormal enzyme metabolism exists in animals, and in an attempt to obtain suitable experimental animals to examine these problems, I have examined 158 monkeys of both sexes—34 *Macca irus*, 75 *M mulatta*, 21 *M nemestrina*, 20 *Presbytis cristatus* and 8 *P obscurus* The results are given in Table 1

Table 1

Species of monkey	No examined	Motulsky test (min)	No examined	Reduced glutathione Incubation	
				before	after
M irus	34	40 – 85	5	98 4 – 70 8	96 5 – 70 0
M mulatta	75	40 – 90	5	91 5 – 80 8	89 6 – 80 4
M nemestrina	21	> 5 h	11	86 7 – 52 0	81 6 – 36 5
P cristatus	20	70 – 120	5	70 8 – 52 4	62 8 – 36 5
P obscurus	8	45 – 80	—	—	—

The blood for Motulsky test was obtained from the ear of the monkeys, and preserved in a small amount of acid–citrate–dextrose–inosine solution The test was usually carried out within 1 h, but always within 12 The time for the glucose-6-phosphate dehydrogenase activity test in normal non-sensitive men was found (in this laboratory) to be between 35 and 90 min while a time of more than 120 min was regarded as indicating a definite deficiency of the enzyme The results in all species of monkeys except one are more or less in agreement with those found in men, although in *P cristatus* the time for this test was slightly elevated compared with that in men The results for all specimens of *M nemestrina*, however, were definitely different, the time being far greater than that found in the other species and in human beings

It was expected that the level of reduced glutathione and the glutathione stability test would also be abnormal in this species, but these were found to be rather normal for all species A fall in glutathione content after incubation was noted in several monkeys, but was not so excessive as is usual in enzyme-deficient human beings

Two blood samples from *M nemestrina* were preserved in acid–citrate–dextrose–inosine solution and sent to Dr E Beutler for the glutathione stability test The values he obtained were within the range found for *M nemestrina* in this laboratory.

It would be of interest to know what the essential basis is for the discrepancies encountered in *M nemestrina* Most probably the different biochemical behaviour is a physiological characteristic peculiar to this special species, since all members of the group showed the same biochemical aberrations It is possible that the carbohydrate metabolism in this species follows different pathways The sex of the animal and the presence or absence of malarial parasites did not seem to influence the results

In a preliminary examination of other animals, the results for the glucose-6-phosphate dehydrogenase activity test were found to be within the normal range in 22 cats and 100 rabbits when compared with those found in men

I thank Dr D E Eyles of the Far East Research Unit, U S Public Health Service (Kuala Lumpur), and his staff for their co-operation , the Division of Malaria of this Institute for assistance , Mr G L Coombs and Mr C S Smith, who did most of the bleeding of the monkeys for glutathione study ; and Dr Ernest Beutler for confirming my glutathione stability test findings in two *M nemestrina*

PATHOLOGY

N-Nitroso-*N*-methyl-urethane: a Potent Carcinogen

RECENTLY, we reported the induction of carcinomas of the fore stomach in rats by nitrosomethylurethane, given in the daily drinking water[1] By intravenous injection, this substance proved to be extremely toxic, the LD_{50} being only 5 mg /kg body-weight Repeated injections of 1 mg/kg every 9 days produced squamous epithelial- and alveolar cell-carcinomas of the lungs in all rats so treated[2] The medium induction time was 400 days, the total amount administered per rat only 8–9 mg The actual carcinogen is diazomethane[3], easily formed from the unstable nitrosomethylurethane by hydrolysis *N*-nitroso-*N*-methyl-*p*-toluene-sulphonamide, which is also used for the preparation of diazomethane[4] but relatively stable, proved to be practically non-toxic and non-carcinogenic when given in the daily diet of rats over their whole life-span[2]

Since nitrosomethylurethane is widely used in chemistry, we feel it necessary to point out that this dangerous substance should be handled with greatest care and be replaced in the preparation of diazomethane by the use of the non-toxic nitrosomethyl-*p*-toluenesulphonamide wherever possible

Induction of Resistance to an Isologous Tumour by Ultra-violet Attenuated Tumour Cells

IN a previous publication from these laboratories it was demonstrated that the intravenous injection of a viable cell suspension of tumour, the *dbrB* adenocarcinoma, indigenous to the strain of origin, the *DBA*/1 mouse, elicited complete resistance to the growth of a subsequent subcutaneous implant of this same tumour, but that many of the animals died of pulmonary tumours resulting from the primary intravenous injection of viable tumour cells[1] Further, when this same strain of animal was pretreated intravenously with similar tumour cells attenuated or killed with alcohol, in an effort to eliminate the development of lung tumours, only partial resistance to challenge growth was effected[2]

In the investigations reported here the work on attenuation has been extended to the use of ultra-violet light as the attenuating agent and the *BW*5147 lymphatic leukæmia in *AKR* mice as the tumour–host combination The ultra-violet source in these studies was a high-pressure lamp having less than 2 per cent of its emission outside of the spectrum range of 2800 Å and 3650 Å All tumour suspensions were irradiated in thin layers in small Petri dishes at a distance of 8 in from the light source, the Petri dishes being immersed in an ice bath to maintain constant temperature The periods of irradiation were 0, 1, 3, 6, and 10 min All animals were treated with 0 1 ml of the irradiated cell suspensions containing 9×10^6 cells per ml and challenged 16 days later with 0 1 ml of a viable tumour cell suspension containing $6\ 75 \times 10^4$ cells per ml

Although resistance to challenge tumour growth was effected by this method of treatment, this resistance was not complete and was manifested principally by a decrease in the rate of challenge tumour growth No tumours developed in any of the animals as the result of treatment with the ultra-violet attenuated cells Best results were obtained with those suspensions irradiated for periods of 6 and 10 min As shown in Table 1, illustrative of 10 experiments so performed, the average tumour growth in these two groups of animals was respectively 73 and 39 per cent smaller than the control animals which received no treatment

Table 1 RESISTANCE ELICITED IN ANIMALS CONDITIONED WITH ULTRA-VIOLET IRRADIATED CELL SUSPENSIONS

Group No	No of animals	Ultra-violet irradiation of conditioning materials (min)	Percentage of animals with primary tumours	Average volume challenge tumours* (cm³)	Percentage of difference control tumour*
I	18	0	100	—	—
II	18	6	0	0 701	−73
III	19	10	0	1 625	−39
IV	10	None	Controls	2 635	—

* Average of volumes of tumours and percentage differences from the control tumour taken on the fourteenth day after challenge

Further investigations revealed that the density of the cell population at the time of exposure to ultra-violet irradiation was of apparently equal importance as time of irradiation in eliciting the inhibiting response The results presented in Table 1 were obtained when the cell population during irradiation was relatively sparse, $9\ 0 \times 10^6$ cells/ml When irradiation was applied to a more dense cell population, $3\ 15 \times 10^7$ cells/ml , and this was afterwards diluted to $9\ 0 \times 10^6$ cells/ml for animal treatment, it was found to be accompanied by enhanced growth of challenge tumour (63 7 per cent) implanted 16 days later (Table 2)

Table 2 EFFECT OF CELL POPULATION DENSITY IN THE ULTRA-VIOLET EXPOSURE CHAMBER ON THE HOST CONDITIONING TO CHALLENGE TUMOUR GROWTH

Group	No of animals	Cell population in irradiation chamber*	Average volume challenge tumours (cm³)†	Percentage of difference from contol tumour†
Exp *A*				
Pretreat	18	$9\ 0 \times 10^6$	0 701	−73 0
Control	10	none	2 635	—
Exp *B*				
Pretreat	10	$3\ 16 \times 10^7$	5 030	+63 7
Control	10	none	3 073	

* All groups (pre-treated) were inoculated with cell suspensions that were irradiated for 6 min

† Averages of volumes of tumours and percentage of differences from the control tumour were taken 14 days after challenge

Apparently the degree of inhibition or stimulation of challenge tumour growth is dependent on the duration of irradiation and the density of the cell suspension irradiated

In an earlier publication from our laboratories, Loofbourow[3] had reported that cells injured by ultra-violet rays secrete substances which absorb in the 2500–2600 Å region of the ultra-violet spectrum and that these substances stimulated growth It was also shown that a greater quantity of this 'growth promoter' was produced when the ultra-violet injury was prolonged[4] To ascertain whether the attenuation of the leukæmia cells in our experiments was accompanied by the production of similar 'growth-promoting' substances, spectroscopic studies of the cell-free media were undertaken These investigations revealed that those suspensions irradiated when sparsely populated produced very low quantities of substances absorbing between 2500 and 2600 Å, while the media from densely populated suspensions contained greatly increased quantities of these materials as compared with non-irradiated cells suspending media These results indicate a correlation with the growth promoting and inhibiting effects of the materials on tumour growth

IMMUNOLOGY

Unresponsiveness to Unrelated Antigens induced by Paralysing Doses of Bovine Serum Albumin

IT is generally admitted that immune paralysis is a phenomenon having a specificity comparable with that of immunity This conception is supported by the observations of Felton *et al* [1] and Dixon *et al* [2] However, it can be shown that, under certain conditions, adult guinea pigs, while in a state of immune paralysis to one protein, fail to be sensitized by another non-related protein antigen injected in quantities suitable for sensitization[3] The present report concerns itself with more detailed results on the question of the specificity of the immune paralysis

The experiments were performed on adult guinea pigs weighing about 400–500 g Immune paralysis was induced by daily administration of 800 mg of bovine serum albumin (BSA) injected by intravenous and intraperitoneal routes This treatment regularly resulted in immune paralysis of the injected adult guinea pigs, tests for sensitization by Schultz–Dale reaction and for serum antibodies by passive cutaneous anaphylaxis and by passive hæmagglutination (*bis* diazobenzidine method)[4] were negative for at least two months after the end of the paralysing treatment

Groups of immunologically paralysed guinea pigs, as well as control animals, were injected at various times after the beginning of the paralysing treatment with 10 mg of alum-precipitated egg albumin or rabbit γ-globulin Sensitizing injections were given by intraperitoneal, intravenous or subcutaneous routes The paralysing treatment was stopped 3–4 days after the sensitizing injection In one experiment, sensitization was attempted 8 days after the end of 15 days treatment Tests for sensitization of treated and control animals were made 15 days after the sensitizing injection by the Schultz-Dale reaction, by the passive cutaneous anaphylaxis and passive hæmagglutination methods The injections of alum-precipitated egg albumin or rabbit γ-globulin always produced a high degree of sensitization in control animals evidenced by maximal Schultz–Dale reactions, positive passive cutaneous anaphylaxis reactions of the sera (dilutions 1/128–1/512) and positive passive hæmagglutinations (dilutions 1/1024–1/4096) We considered those animals as non-sensitized which presented negative Schultz–Dale reactions, negative passive cutaneous anaphylaxis reactions with undiluted sera or a titre of passive hæmagglutination less than 1/32

The results of these experiments are reported in Table 1 It appears that if the injection of egg albumin or rabbit γ-globulin was made simultaneously with the first injection of bovine serum albumin, all treated guinea pigs were found to be sensitized

Table 1 GUINEA PIGS IMMUNOLOGICALLY PARALYSED WITH BOVINE SERUM ALBUMIN (800 MG/DAY/ANIMAL) AND SENSITIZED WITH AN UNRELATED ANTIGEN

Sensitizing antigen	Route of injection	Day of sensitization after the start of the immune paralysing treatment						
		0	3	6	8	10	14	18
Ovalbumin 10 mg alum pptd	I P	5/5*	1/2	3/5	0/2	0/5	—	—
	I V	—	2/3	1/3	—	0/4	—	—
	S C	—	—	—	—	3/3	2/4	0/3
Rabbit γ-globulin 10 mg alum pptd	I P	5/5	—	3/5	1/5	0/4	—	—
	I V	—	3/5	2/3	—	0/5	—	—
	S C	—	3/3	—	—	3/3	—	0/3

* Number of animals sensitized/total number of animals injected with the sensitizing antigen
I P Intraperitoneal, I V, intravenous, S C, subcutaneous

However, if the sensitizing antigens (egg albumin or rabbit γ-globulin) were injected after the beginning of the paralysing treatment, the proportion of sensitized animals became smaller as the interval between the start of the paralysing injections and attempted sensitization was increased When the injection of egg albumin or rabbit γ-globulin was given on the 10th day of the paralysing treatment, by the usual route (intraperitoneal or intravenous), no animals were found to be sensitized When sensitizing injections were made subcutaneously, the length of the paralysing pretreatment, necessary to inhibit sensitization, was even longer, only sensitizations attempted on the 15th–20th day of the treatment with bovine serum albumin were inhibited

The inhibition of sensitization to the non-related antigens observed when immunization is attempted under the above conditions is long lasting Guinea pigs tested two months after a sensitization attempted during the paralysing treatment had no antibodies to the sensitizing antigens as well as none to the paralysing antigen The capacity of paralysed animals to be sensitized against another non-related antigen is nevertheless rapidly restored guinea pigs treated with the same doses of bovine serum albumin during 15 days were readily sensitized if injection of alum-precipitated egg albumin was performed 8 days after cessation of the paralysing treatment This is in contrast to specific immune paralysis which may last 3–6 months, depending on the quantity of the paralysing antigen injected

These experiments support the conclusion that immune paralysis, induced in adult guinea pigs, is specific only in an early and in a late phase, that is, during the first few days of treatment and after the end of this treatment During the series of paralysis-inducing injections, as the treatment is prolonged, the immune unresponsiveness may spread to affect other protein antigens unrelated to the one used to induce immunological paralysis

Binding of Ragweed Antigen labelled with Iodine-131 by Sera of Untreated Allergic Subjects

IT has recently been shown that purified horse serum albumin and two other mammalian serum proteins labelled with iodine-131 were bound by sera of allergic individuals with cutaneous reactivity to these proteins[1] The binding was demonstrated by immunological precipitation of human γ-globulin from a pre-incubated mixture of human serum and labelled antigen The quantity of antigen in the precipitate was then estimated by its radioactivity This procedure has been applied to the detection of iodine-131 ragweed antigen combined with the sera of untreated ragweed-sensitive individuals

A highly purified antigen and a high specific activity of labelled antigen are required for best results with this procedure The purified ragweed used was supplied by T P King of the Rockefeller Institute The specific activity of the labelled ragweed preparations varied from 1 to 10 mc of iodine-131 per milligram of antigen *N* Routinely, either 0 05 ml undiluted or 0 5 ml of ten-fold diluted human serum was incubated for 2 h at 37° C with varying amounts of labelled ragweed Sufficient rabbit anti-human γ-globulin was then added to precipitate all the human γ-globulin in the mixture and incubation at 37° was continued for another hour Radioactivity of the precipitate and of the supernatant fluid was measured A correction was made for the quantity of supernatant fluid entrained in the precipitate The percentage of the total activity found in the precipitate and the antigen nitrogen added was recorded A plot of such results was made for each serum with the former values as the ordinate and the logarithm of the latter values as the abscissa In all instances a flat region parallel to the abscissa, which was indicative of maximal binding, was observed in antibody excess followed by a region of inhibition as the quantity of antigen added was increased This type of curve is also typical of the binding of labelled horse serum albumin by sera of individuals sensitive to this protein[1], of the binding of labelled insulin by sera of some insulin-resistant diabetics[2] and of the binding of purified antigens by precipitating rabbit antisera[3]

A number of different sera were tested by this technique The maximum percentage of binding for several groups of sera, each tested in antibody excess, is shown in Table 1 The sera of all untreated individuals with immediate cutaneous reactivity to ragweed and all who had received hyposensitizing injections demonstrated significant binding of labelled antigen The reaction was inhibited in each instance in the presence of excess unlabelled whole ragweed extract The sera of non-atopic individuals who had not received injections of ragweed were negative

Table 1 BINDING OF RAGWEED ANTIGEN LABELLED WITH IODINE-131 BY HUMAN SERA

Subject status	No of individuals	Maximum percentage binding*
Atopic, untreated	17	30 ± 6
Atopic, treated	5	50 ± 3
Non-atopic, untreated	7	6 3 ± 2 5

*Expressed as mean ± average deviation

The maximal binding of 30–50 per cent suggests that 30–50 per cent of the labelled antigen used is immunologically competent with respect to homologous antibodies in human sera The difference in maximum binding of the immunized and non-immunized groups suggests that more than one antigen is present in the purified ragweed preparation It is evident that the ability to detect binding will decrease with decreasing purity of the labelled antigen When single pure antigens are available it will be possible to determine quantitatively the binding capacity of individual sera

RADIOBIOLOGY

Strontium-90 Plasma-levels and Excretions in Young Adults

WITH the future of atmospheric testing of nuclear weapons uncertain, it remains of interest to determine in man the metabolism of strontium-90 derived from past tests Considerable information on strontium-90 retention has been obtained from analysis of human bones[1,2] and teeth[3], from work with animals, from the metabolism of stable strontium[4,5], and from the use in man of strontium-85[6,7] This communication reports some implications of a study of strontium-90 metabolism conducted on ten young adult volunteers who received a constant diet containing approximately 1 1 g of calcium per day on a metabolic ward for 3 periods of 6 days each The intake of strontium-90 during the study averaged 13 4 $\mu\mu$c /day, most of it ingested with milk Prior to the study, less milk was probably consumed, and less strontium-90 ingested

Fæcal excretion of strontium-90 averaged 86 per cent of intake Average net absorption, disregarding the amount absorbed and then re-excreted in the stool, was therefore 14 per cent, with a standard error of 3 1 per cent Absorption calculated from studies with strontium-85 on patients between 50 and 75 years of age averaged about 20 per cent[8], and 5 per cent was re-excreted in the stool, the net absorption of 15 per cent being in good agreement with the present results.

Table 1 lists values of strontium-90 found in urine, compared with urine values expected from intake. Calculations were made on the assumption that 20 per cent of the strontium-90 ingested was absorbed, and that the amount excreted in the urine depended on urinary calcium, the formula first used[8] being slightly modified[9]. The 12-day urinary excretion of strontium-90, in per cent of absorbed intake, is

$$80 - \frac{8000}{x + 100}$$ where x is urinary calcium in mg/day.

To allow for excretion of strontium-90 ingested before the study began, and for excretion beyond a 12-day period, this is multiplied by 1.2 (ref. 8). If intake prior to the study was lower than during the study period, as seemed probable, this factor may be slightly too great.

Table 1. STRONTIUM-90 IN URINE AND IN PLASMA COMPARED WITH VALUES CALCULATED FROM INTAKE

Volunteer	Urinary Ca (mg/day)	Urinary ^{90}Sr (μμc./day) predicted	Urinary ^{90}Sr (μμc./day) found	Plasma ^{90}Sr (μμc./l.) calculated from urine	Plasma ^{90}Sr (μμc./l.) calculated from food
1	45	0.91	0.69	0.315	0.416
2	148	1.75	1.2	0.222	0.323
3	91	1.20	0.66	0.171	0.311
4	360	1.97	1.78	0.204	0.226
5	75	1.05	0.78	0.234	0.315
6	61	0.94	0.66	0.234	0.333
7	110	1.29	1.0	0.226	0.291
8	159	1.51	2.0	0.353	0.226
9	96	1.19	1.3	0.324	0.297
10	202	1.63	1.7	0.260	0.249
Average	134.7	1.344	1.177	0.254	0.303

Renal clearances of strontium-90 were calculated from calcium clearances[8,9], and strontium-90 in plasma was determined by dividing urinary excretion by clearance.

Correlation between urinary calcium and urinary strontium-90 found was 0.727, significant at the 0.02-level, the equation of the regression line being $y = 4.50 + 0.034x$, where y is urinary strontium-90 as per cent of intake and x is urinary calcium in mg/day. Table 1 indicates that urinary strontium-90 could be predicted reasonably well from intake and urinary calcium, the correlation between predicted and found values being 0.785, significant at the 0.01-level. The average value found was 88 per cent of that predicted, possibly because retention was greater in our volunteers than in older persons.

The correlation between plasma values calculated from intake and from urine values was 0.171, not significant, while the average calculated from urine values was 84 per cent of that calculated from intake. On the assumption that a litre of plasma contains 100 mg calcium, the ratio of average strontium-90/calcium in plasma to that in food is 3.03/13.4, or 0.23, if plasma levels are calculated from food, and 2.54/13.4, or 0.19, if calculated from urine. Harrison[10], by direct analysis of 2 pools of plasma, found strontium-90 values of 1.1 and 1.4 μμc./g calcium on an assessed intake of 6 μμc./g, corresponding to an observed ratio (plasma/diet) of 0.18 and 0.23 respectively.

Table 2 lists strontium-90/calcium ratios in the stool, as well as ratios for stool/food. The coefficient of variation of the stool/food ratios was 19 per cent, while that of urine/food ratios, not listed individually, was 29 per cent. The use of the strontium-90/calcium ratio in urine has been proposed by Schulert[11] and by Comar and Georgi[12] for estimating the strontium-90/calcium ratio in food. The lesser variability of the stool/food ratio suggests that use of the strontium-90/calcium of stool would be superior to that of urine. Schulert's ratio is the reciprocal of the observed ratio, urine/diet (O.R.) of Comar and Georgi. Schulert's average ratio of 2.11 thus corresponds approximately to an average O.R. of 0.47. For his Peruvian and Vietnamese groups, the 95 per cent confidence limits of the O.R. may be calculated as 0.41–0.75 and 0.26–2.5 respectively. The data for Comar and Georgi's O.R. for rats (their Table 1) can be calculated to give a coefficient of variation of 54 per cent. The data in their Table 2, for human subjects give a coefficient of variation of 36 per cent. However, their data are drawn from a heterogeneous population, the values for children, first group of five, their Table 2, differing significantly from the values for adults, second group of 5. (Their third group includes some of our own volunteers, whose data are reported here.) Even for adults, however, in view of the difference between the values of Schulert and of Comar and Georgi, an average value of the ratio should be used with caution.

Table 2. STRONTIUM-90/CALCIUM RATIOS IN STOOL, AND IN STOOL COMPARED WITH FOOD

Volunteer	μμc. ^{90}Sr/100 mg Ca Stool	Stool/Food
1	1.49	1.11
2	1.60	1.19
3	1.96	1.72
4	1.86	1.65
5	1.45	1.31
6	1.66	1.43
7	2.19	1.99
8	1.96	1.73
9	2.01	1.70
10	2.09	1.82
Average	1.827	1.565
S.E.	0.082	0.091
Coeff. variation	14%	19%

As strontium-85 excretion rises less rapidly than urinary calcium[8,9], a negative correlation was expected between urinary calcium and the urinary strontium-90/calcium ratio. This correlation was found to be −0.680, significant at the 0.05-level. This suggests that the value of this ratio for estimating the corresponding ratio in food can be increased by taking urinary calcium into account. However, when urinary calcium is very low, the fraction of the ingested strontium-90 appearing in the urine is small and its determination highly uncertain. By contrast, the major portion of the ingested strontium-90 is found in the stool, the ratio of average stool strontium-90 to average urinary strontium-90 in the present study being more than 9/1. The stool/urine ratio is much greater for individuals with very low urinary calcium than for the average person in the present group, a collection of urine from a single individual of two weeks or more being needed to provide as much strontium-90 for analysis as a single day's collection of stool.

In addition, the absolute amounts of strontium-90 in food and urine bear no simple relation to each other, whereas the amount of strontium-90 in food may be calculated from that in stool by use of the factor 1.0/0.86 = 1.16. Stool analyses are therefore superior to urinary assays for strontium-90 on a number of counts, the most important of which are that they provide more accurate estimates of the strontium-90/calcium ratio in food and good estimates of total strontium-90 ingested.

This work was supported by the U.S. Atomic Energy Commission, and the analyses for strontium-90 were performed in the Atomic Energy Commission's Health and Safety Laboratory in New York.

Cytoplasmic Localization of Deoxyribonucleic Acid in *Allium cepa*

IT is believed generally that the normal complement of deoxyribonucleic acid (DNA) occurs exclusively on the chromosomes. However, that this is true of all plant cells has been contested. Thus ultra-violet absorption microscopy was used to show that it occurred predominantly in the cytoplasm of the root meristem cells of *Vicia faba* which had been treated with pectinase[1]. These results were supported by results obtained from fractionated homogenates of roots of *V. faba* and *Allium cepa*[2]. It was claimed that this localization was dependent on the lifelike preservation of the cytoplasmic particles, and that if these were damaged in any way the DNA would diffuse to the nuclei. However, these results were inadequate, partly because of the extreme variability of the commercial pectinase samples that were available[1], and partly because it was just as reasonable to postulate that homogenization caused the DNA to diffuse from the nuclei instead of to the nuclei[3].

The development of the controlled low-temperature sectioning technique[4] has made available a routine procedure by means of which the cytoplasm can be preserved in a life-like manner. The use of this technique, in conjunction with autoradiography, has now allowed the re-investigation of the localization of DNA in these cells.

Bulbs of *A. cepa* were grown in tap-water until the roots were about 2 in. long, when they were transferred to tap-water containing tritiated thymidine (sp. act. 0·360 mc./mM) at a concentration of 1 μc./ml. Root tips were removed from each plant after feeding for periods of 24 and 48 h, and were washed in tap-water. The majority were immersed in 5 per cent aqueous polyvinyl alcohol[4] for 2 h prior to freezing and sectioning. For comparison, other roots were treated by the more customary cytological procedures which, whether by artefact or not, ensure that all the DNA is nuclear. Thus after fixation for 3 h in Clarke's[5] acetic-alcohol, some were used for Feulgen squash preparations and others were embedded in paraffin wax and sectioned. Stripping-film autoradiographs[6] were set up with preparations from all three methods. Difficulty was encountered in the preservation of the frozen sections during the photographic processing of the autoradiographs. It was not possible to fix the sections prior to setting up the autoradiographs because many chemical fixatives destroy the cytoplasm, and it was postulated[1] that such damage would cause diffusion of the DNA to the nucleus. Other fixatives, such as the Newcomer–Zirkle technique[7], which might have produced good cytological effects, could not be used since they affected the photographic emulsion. The apposition method of autoradiography was considered inadvisable, both because of the poorer resolution of the method and because the recombination of the developed autoradiograph and the section depend on the worker.

It has been found that fixation of a frozen section with 10 per cent formalin can be achieved in the presence of a photographic emulsion without causing any damage to the emulsion. This form of fixation does not seem to cause an increase in the background count of the autoradiograph (Brain, E. B., private communication). Consequently, the exposed emulsion and frozen section were immersed for 15 min in 10 per cent formalin immediately prior to photographic development of the autoradiograph; at least this preserved the cell walls and the outline of the cell nuclei.

In sections of meristematic cells which had been fixed in acetic-alcohol and embedded in paraffin wax, as well as in those which had been subjected to fixation and macerated with hot acid, the radioactivity was localized only in the interphase and mitotic chromosomes. This radioactive, chromosomal material was insoluble in 1 per cent trichloroacetic acid at room temperature; however, extraction with 5 per cent trichloroacetic acid at 95° C for 15 min or by treatment with a suitably controlled deoxyribonuclease digestion, completely removed the labelled material. Thus, this Feulgen-positive, tritium-labelled material had the properties generally considered characteristic of DNA.

By contrast, in the frozen sections, a predominantly cytoplasmic localization was found in 82 per cent of the labelled cells of roots fed for 24 h, and in more than 90 per cent of labelled cells in those fed for 48 h. As in the paraffin sections, this labelled material in the frozen sections was insoluble in 1 per cent trichloroacetic acid at room temperature, but was extracted with a suitably controlled digestion with deoxyribonuclease or by 5 per cent trichloroacetic acid at 95° C for 15 min. That is to say, this tritium-labelled material in the frozen sections behaved like the DNA of the paraffin sections.

Consequently, this difference in the localization of the labelled material between the sections prepared by the two techniques is a true difference in the localization of the DNA, and would seem to depend on the mode of preparation.

It was postulated that the DNA would diffuse to the nuclei if the cytoplasmic granules were destroyed. Accordingly, frozen sections were treated with 1 per cent trichloroacetic acid prior to setting up the autoradiographs; the labelling was then found to be predominantly nuclear.

Grain counts made from both the paraffin and frozen sections showed that the mean number of grains per cell was of the same order for both types of section (Table 1). Furthermore, the ratio of the number of grains in the cytoplasm to that of the nucleus in the frozen sections was reversed after these sections had been treated with dilute acid (Table 2)

Table 1

Cell No	Paraffin section	Frozen section		
	Grains per nucleus	Grains per nucleus	Grains per cytoplasm	Total grains
1	39	9	23	32
2	40	12	22	34
3	58	10	51	61
4	51	15	51	66
5	73	—*	—*	93
6	100	9	19	28
7	68	25	45	70
8	42	17	54	71
9	72	14	65	79
10	57	8	28	36
Average	60	13 2	39 8	57

Grain counts, corrected for background, showing that both paraffin embedded and frozen sections have similar numbers of grains per cell Standard deviations are not given since these may correspond to a bimodal distribution which may be equivalent to 2 c and 4 c values

* Only total cell count given because of difficulty in distinguishing the nucleus sufficiently well

Table 2

Cell No	Untreated frozen section		Adjacent frozen section Treated 1 per cent TCA for 5 min

12	—*	—*	77 7	22 3
Average	22 6 ± 7 1	77 3 ± 7 1	81 8 ± 10 3	18 2 ± 10 4

Percentage of grains per cell over nucleus and cytoplasm demonstrating the reversal of the distribution of the grains on damaging the cell cytoplasm with dilute acid

* Only total cell counts given because of the difficulty of distinguishing the nuclei sufficiently clearly

From the preceding data it appears that not only is the labelled material of the frozen sections similar in behaviour to that of the paraffin sections, but also quantitatively similar Further, the behaviour of this material is such that it must be considered to be DNA It must be assumed that 'acid-soluble' nucleotides have been lost when the cryostat sections are immersed in water, during the autoradiographic procedure, this extraction of the so-called 'acid-soluble' fraction by the water will be facilitated by the thinness of the section, and by the fact that the protoplasm is not coagulated[4] The only difference, therefore, between the paraffin and frozen sections is one of the localization of the DNA Thus, confirmation has been obtained for the original data from which it was claimed that most of the normal complement of the DNA of the interphase root meristem cells of *A cepa* was in fact localized in the cytoplasm That treatment with acid caused most of the DNA to be found in the nuclei is further confirmation of the hypothesis that this cytoplasmic localization of the DNA is indeed dependent on the integrity of the cytoplasmic particles

Role of Mercaptoethylamine in Repeated Monthly Exposures to Gamma-Radiation in Mice

The beneficial effect of administering mercaptoethylamine (MEA) to mice prior to a single acute exposure to X- or γ-radiation as reported by Bacq *et al* [1] has been demonstrated repeatedly in other laboratories Daily administration of MEA or other protective amino-alkylthiols to reduce the biological damage due to daily radiation exposure has not been successful[2] and may even be harmful[3] The role of such compounds in reducing damage to repeated radiation exposures once recovery is virtually complete has not been explored The experiment reported here was designed to determine how often mice could be challenged by a large exposure to radiation with adequate MEA administered before each such exposure A period of 30–32 days between exposures was selected as the time by which recovery from acute damage would be complete

Two hundred female Walter Reed Bagg Swiss mice, 6–7 weeks of age, 20–25 g in weight, were divided into two groups, a group of 80 was to be exposed monthly with 150 mg/kg of MEA (base) 1 5 per cent solution in distilled water, *p*H 7–7 5 freshly prepared, administered intraperitoneally 10–15 min prior to exposure The remaining group of 120 mice would serve as controls so that age would not be a factor The controls received comparable volumes of saline intraperitoneally prior to exposure Radiation was done in a specially designed cobalt-60 irradiator that has a radiation chamber of 2 ft × 2 ft × 4 in The irradiator contains approximately 1,100 c

cobalt-60, half above and half below the radiation-chamber. The rate varied from 116 r./min. to 110 r./min. during the period of this experiment.

Mice were confined in a circular plastic holder large enough to accommodate 50, and shallow enough to prevent huddling during the exposure. The holder was slowly rotated on a turntable within the radiation chamber, placed so that the animals were in the centre of the chamber. All exposures were 975 r. (approximately 9 min.) as measured in air at the mid-position of the animals. Post-exposure the mice were housed 10 to a wire-bottom cage, each cage containing treated and control mice. Mortality was recorded daily.

In the first exposure 80 mice were given MEA and exposed with 20 controls, in two groups of 50, 40 treated and 10 controls. The second exposure was 60 treated (survivors of first exposure) and 40 controls. By the fourth exposure the supply of age controls was exhausted so mice 6–7 weeks of age were used as controls.

The results are shown in Table 1. For the first three exposures survival in the treated mice is good. The results are consistent when the two internal and independent groups are compared for each of the first three exposures. Recovery from the third exposure was not complete 32 days later as the mice were thin, their coats were ruffled and there was gross evidence of diarrhœa. In spite of this they were exposed for a fourth time with the result as shown. Recovery from the fourth exposure was not complete 32 days later as the surviving mice appeared worse than after the third.

Better survival for the fourth and fifth exposures might have been obtained if a longer period of recovery had been allowed although a 30–32-day recovery period appeared ample after the first and second exposures. Mortality during the fourth and fifth periods was probably influenced by residual damage from the preceding radiation exposures although this cannot be quantitated from these data. It would have been of interest if treated mice could have been saved after each exposure to determine long-term survival after two, three, four and five such exposures. Also of interest would have been a third group of mice which without MEA received 490 r. each time treated mice received 975 r. With such data the actual protection offered could be described more accurately. There was increasing acute toxicity from later injections of MEA but this is probably due to the poorer condition of the mice as mentioned previously.

In spite of these faults, it is apparent that MEA does offer considerable protection to at least three repeated fully lethal exposures provided 30–32 days are allowed between exposures for recovery. After the third exposure the results may be obscured by residual damage due to a total exposure of several thousand r. There is no evidence of increased sensitivity to radiation exposure under these conditions.

BIOLOGY

Photoperiodism in Relation to the Origin of African *Trifolium* Species

THE genus *Trifolium* contains several hundred species of which the majority occur in the north temperate regions above 30° N. The genus is also represented in South Africa and South America, while a little-known group of *Trifolium* species occurs in the highlands of equatorial Africa. Some of the African species are promising pasture plants and are assuming importance in certain areas.

It is generally accepted that the genus *Trifolium* originated in the Mediterranean region. Gillett's[1] monograph on the African species contains some interesting observations on the origin and distribution of these clovers. One entire sub-section, the Ochreata, is at present confined to tropical Africa, and Gillett expresses the view that this group probably originated in equatorial Africa. The distribution of the other African species, as depicted in the remaining sections and sub-sections, is characterized by a great concentration of species in northern Ethiopia and Eritrea, and is consistent with the theory of the migration of the genus from the Mediterranean region. On the other hand, it has been suggested that the tropical African species, together with those inhabiting the mountains in South America and California, are relics of a truly ancient population[2].

Studies of photoperiodism have previously been applied as an aid in determining the origin and dispersal of plants[3–6]. So far as can be ascertained, the photoperiodic responses of at least 22 *Trifolium* species have been determined to date[7–9]. These include numerous species indigenous to the southern Mediterranean region (30–35° N.) and to Europe. All species have been classified as long-day plants of varying sensitivities. So far, no similar studies appear to have been published in respect of African clovers.

A summary of some of the recent results from an experiment on the reaction of five African clovers

Table 1. EFFECT OF DAY-LENGTH AND NIGHT TEMPERATURE ON THE FLOWERING RESPONSE OF AFRICAN *Trifolium* SPECIES
Values represent mean number of inflorescences formed per plant (means of 18 or 21 plants per treatment per species)

Treatment		East African				South African
Night temperature (° C.)	Day-length (h)	*T. usambarense*	*T. rueppellianum* var. *ruepellianum*	*T. semipilosum* var. *semipilosum*	*T. cheranganiense*	*T. africanum* var. *lydenbergense*
10	8	163.7	27.5	2.8	12.8	0.0*
	12	88.8	5.1	5.2	15.0	0.05
	16	0.7	4.0	7.0	17.3	19.8
15	8	139.6	40.2	1.7	6.1	0.0*
	12	55.9	10.0	2.9	10.8	0.0*
	16	0.2	4.3	7.0	13.8	23.9
21	8	99.3	8.0	0.7	1.5	0.0
	12	14.0	8.8	3.9	3.6	0.05
	16	0.0*	4.1	6.4	5.4	10.3

* The plants in these treatments were entirely vegetative as determined by microscopic examination of growing points.

to night temperature and length of day is presented in Table 1. The plants were grown in pots, kept in the open by day, and transferred in the afternoon to temperature-controlled growth rooms where the appropriate day-lengths were provided. The plants were harvested after 6.5 months. From Table 1 it is clear that the characteristic long-day flowering response of Mediterranean and European species did not obtain for all the African clovers. The reaction of *T. usambarense* Taub. was that of a sensitive short-day plant, with an optimum photoperiod of less than 12 h. *T. rueppellianum* Fres. also responded as a short-day plant, but appeared to be less sensitive than *T. usambarense*. The remaining three species all behaved as long-day plants, *T. africanum* Ser. from the eastern Transvaal (26° S.) being especially sensitive to photoperiod. (It should be noted that the terms 'quantitative' and 'qualitative' long- or short-day plants have been avoided in support of the recent appeal by Best[10], who showed by means of response curves that these terms are neither justified nor tenable; results of the present work (not shown) support his findings.)

The present results indicate that while genotypic differences in flowering behaviour may not be apparent between species when observed under the 12-h day-length régime of the equator, they may become clearly revealed when the material is transferred to different environments.

The physiological evidence in support of the existence of genes which determine the short-day flowering habit of *T. usambarense* in the sub-section Ochreata would, on the face of it, appear to support the hypothesis of Gillett[1], based on morphological and ecological evidence, that this presently endemic group evolved in tropical Africa. It is significant that *T. usambarense* is reported to show the greatest adaptation to tropical conditions, occurring at only 850 m near the equator[1].

The unusual existence of long-day plants on the equator does indeed suggest that *T. semipilosum* Fres., *T. cheranganiense* Gill. and related species may well have evolved from plants of the higher latitudes, probably of the north temperate region. It should be noted that this does not imply that all species and strains in the Ochreata can be classified as short-day plants or that the converse applies to the Euamoria.

On the basis of the available evidence there does not appear to be sufficient support for the view that the tropical African species are relics of an ancient population. It seems more likely that the Ochreata evolved from the widespread Euamoria some time after species of the latter group reached the African Highlands.

The fact that the predominant and aggressive Ochreata have, in recent times, failed to move out of a relatively narrow tropical band into apparently suitable areas in the higher latitudes to the north and south accords with the views of Allard[5], namely, that, among other factors of climate, day-length exerts a rigid control over the northward and southward distribution of many plants, and prevents their free colonization of lower or higher latitudes.

It is hoped that investigations in progress on the *Rhizobium* affinities and photoperiodic reactions of additional species and strains of African clovers will shed more light on the subject.

I thank Prof. N. Grobbelaar, head of the Margaretha Mes Institute of Plant Physiology and Biochemistry, for the use of controlled environment facilities, the Grassland Research Station, Kitale, Kenya, for supplying seed of the East African species, and the Director, Royal Botanic Gardens, Kew, Surrey, for identifying the material.

Dry-Matter Production by Evergreen Perennials

SOME years ago, Heath and Gregory[1] made the generalization that the mean net assimilation-rate was constant for species and environments. Subsequent work has demonstrated some large departures from their mean value of about 0.55 g/dm^2/week, although Watson[2] has more recently supported the validity of their general conclusion that leaf growth is the main yield determinant. Most of these studies have been made on annual crop plants and very few estimates are available for mean net assimilation-rates of perennials.

Recent work on the growth of aerial parts of the oil palm, *Elaeis guineensis*, Jacq., has indicated that a mature plantation, aged 17–22 years, has an annual crop growth-rate of 1.95 × 10^4 kg/hectare, a value very similar to that obtained for *Pinus*[3]. This is associated with a mean leaf area index of 4.9, and a leaf area duration of more than 250 weeks. The mean annual value for net assimilation rate is therefore 0.078 g/dm^2/week, a figure lower than any quoted in the literature. In terms of efficiency of solar energy conversion, the annual dry matter production (estimating 1 g dry matter as equivalent to 3,740 calories) represents 0.56 per cent of total radiation or 1.22 per cent of energy utilization in the spectral region 400–700 mμ (when the available energy in this spectral region is taken to be 0.46 of the total energy received). In terms of carbon fixation (assuming the total dry weight to contain an average carbon content of 40 per cent) the annual value is 2.1 g carbon/m^2/day.

Nursery oil palms have a higher crop growth-rate; in a spacing experiment the maximum value for the production of dry matter, including roots, was 0.58 g/dm^2/week over a 27-day period (equivalent to 3.03 × 10^4 kg/hectare/yr if this rate were maintained throughout the year). This figure corresponds to solar energy conversion of 0.81 per cent for total radiation, 1.76 per cent for radiation of wave-length 400–700 mμ, and 3.3 g/carbon/m^2/day.

The crop growth-rate values obtained for the adult oil palm are very much lower than the few other data obtained in the tropics. Values of 7.2 and 7.8 × 10^4 kg/hectare/yr are reported[4,5] for dry matter accumulation by sugar cane, with similar values for papyrus[6]. Preliminary data for the dry-matter production of the rain forest trees *Tectona*, *Altingia* and *Ochroma* in Java are 5 4, 6 8 and 6 9 × 10⁴ kg/hectare/yr, respectively[7], while the aerial parts of the grasses *Panicum maximum* and *Pennisetum purpureum* yield 2 3 and 3 4 × 10⁴ kg/hectare/yr respectively in a climate similar to that in which the oil palm data were obtained[8]

In annual crops yield differences are usually accounted for by differences of leaf area index or leaf area duration In the oil palm, as in other evergreen perennials, leaf area duration must be nearing the maximum value (apart from climatic and edaphic limitations), and the interception of solar radiation must be nearing maximum efficiency The very large difference between the crop growth-rate of the adult oil palm and other tropical plants must be due to differences in mean net assimilation-rate, rather than in leaf area index or leaf area duration The variation in net assimilation-rate must be of greater importance in many cases than differences in leaf area and leaf production, which, from work on annual plants, have been assumed to play the greater part in yield determination

Recent results published by Warne[9] for the crop growth-rate of kale indicate that net assimilation-rate in annuals may also assume greater importance than leaf area index or leaf area duration

If allowance is made for the absence of root weight data for the adult palms, there is still a very large difference between the adult palm and nursery palm production This is undoubtedly due to the effect of age in reducing the proportion of photosynthesizing to total living parts, which would reduce the mean net assimilation-rate to a low level despite a possibly high rate of photosynthesis Monsi[10] comes to the same conclusion in his consideration of the perennial-leaf tree system of dry-matter production

Yield increases in evergreen perennials must be looked for, not from increases in leaf area or leaf area duration, but from improvements in the net assimilation-rates

Determination of the Quantity of Carbon and Nitrogen in the Rhizosphere of Young Plants

HILTNER[1] introduced the concept of the rhizosphere to express the zone in which the living root exerts an influence on microbes in the soil Much information has been gleaned since then on the microflora of the rhizosphere and on the substances given off by the roots, but there is much less information on the total quantities of organic substances which the roots lose The facts so far known are in relation to plants grown in sterile nutrient solutions or in sterile quartz sand without any adsorption capacity[2-4] The quantities of nitrogen given off by leguminous plants can be estimated from the total nitrogen present in non-leguminous plants cultivated together with the former in a nitrogen-free soil[5,6]

Scarcely anything is known about the total quantity of the substances given off by the roots, especially concerning their carbon and nitrogen amount and their C/N ratio in a soil with a natural absorption capacity in which the rhizosphere is somewhat limited in space In general, the extent of the rhizosphere is insufficiently known In a recent publication Papavizas and Davey[7] discussed this subject, and made estimations from a set of micro-borings in the rhizosphere of young lupins In these small soil samples they estimated the total amounts of bacteria, fungi and actinomycetes using the dilution plate technique The *R/S* values (total numbers of micro-organisms in the rhizosphere/total numbers of micro-organisms in non-rhizosphere soil) were thus obtained, and indicated that the rhizosphere is rather extensive and can have a radius up to 18 mm in unamended soils In amended soils the rhizosphere may be negligible

We have attempted to obtain exact information concerning the quantities of organic matter (that is, carbon and nitrogen) given off by the roots and the distance which these substances spread from the root surface The roots are forced to grow in a small chamber made from a thin nickel plate (0 1 mm thick) densely perforated with punctures 60μ in diameter This chamber is placed in a big container, and both are filled with the same substrate The space within the perforated chamber becomes filled with a mat of roots, and consequently may be considered to belong entirely to the rhizosphere, while the space outside the chamber is still in connexion with the roots and serves as a stock of moisture and nutrients

The substrate used consisted of a mixture of 70 per cent pure sand, 25 per cent finely ground potassium-feldspar and 5 per cent kaolinite with some finely granulated pumice stone to improve the structure and aeration of this artificial soil In some experiments the amount of feldspar and kaolinite was higher This substrate is very poor in organic substances, containing only 0 022 per cent carbon on dry-weight basis

200 ml of a solution of Crone's mixture, containing 1 5 g/l, is added to the content of every container holding about 600 g of dry soil During the experiment water is added if necessary

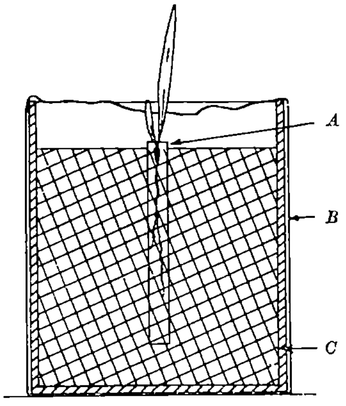

Fig 1 Diagrammatic scheme of the apparatus *A*, Root chamber, *B* black plastic sheet to prevent growth of algæ, *C*, glass pot with soil

Table 1 ROOT EXCRETIONS OF CARBON AND NITROGEN (MG)

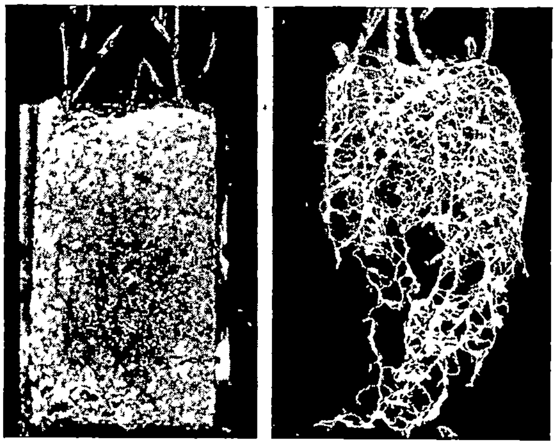
* Soil with an enhanced clay minerals content

† Experiments under conditions as for sterile cultures

—, No differences with control values

Wheat and spinach were grown for 2 months, vetch for 6 weeks In each pot 4 plants were grown



A B

Fig 2 *A*, root chamber opened, the roots grown in it are visible, *B*, the same roots, washed free from soil

The nickel plate proved not to be harmful to the roots and had scarcely any oligodynamic effect on the micro-organisms in the soil It is also inert against the substances produced by the roots and is impervious to the roots

In the upper part of the root chamber germinated sterilized seeds are planted and allowed to grow for a required period A diagram of the apparatus is shown in Fig 1

To determine the amounts of carbon and nitrogen in the rhizosphere the content of the opened root chamber (Fig 2) is washed free from soil The washing is dried at 105° C and analysed (Table 1, *a*) Further analyses are performed on the 1-cm thick layer of soil surrounding the root chamber (*b*) and on the rest of the soil in the container (*c*)

The nitrogen is determined by the micro-Kjeldahl method, the carbon by the dry-combustion method

The preliminary results so far obtained are given in Table 1 The carbon figures are corrected for the blank (0 022 per cent carbon), the nitrogen figures could not be corrected in this experiment since ammonium nitrate was added in the Crone mixture, they are therefore less reliable

A distinct concentration gradient from the root chamber outward is apparent in these experiments The technique consequently proved workable, but the distance of diffusion of the substances given off is smaller than was expected This may be brought about by the constant flow of water and solutes towards the roots as a result of the transpiration of the plants

Enhancement of the sorption complex of the soil seems to lead to larger amounts of carbon preserved in the rhizosphere

When considering the figures in Table 1 it must be realized that these experiments were not performed under aseptic conditions Part of the organic substances given off by the roots certainly had already been decomposed by micro-organisms The results therefore represent the minimum of excretion, correct figures presumably being higher

Following and improving this technique further, experiments are being started to obtain more information about the total quantities of carbon and nitrogen produced in the rhizosphere of different plants of various ages, grown under sterile, as well as non-sterile circumstances, in soils of different composition It might be expected that thereby a better insight will be gained in the part played by the rhizosphere in the cycle of carbon and nitrogen in the soil, providing us also with new information about formation and disintegration of humus

Longevity of *Schizophyllum commune* II

IN 1945 the late G R Bisby[1] reported that sporophores of the agaric *Schizophyllum commune* Fr collected by A H R Buller[2] at Winnipeg in 1909 and 1911 and freeze-dried in 1910 and 1912 had retained their viability up to 35½ years Pure cultures were obtained and in June 1945, two months after submitting his communication for publication, they developed sporophores

On December 17, 1949, Bisby opened another tube containing two pieces of sporophore freeze dried in 1912 and afterwards kept for three weeks in liquid air at −190° C (Buller[2]) One piece (collected in 1909) was dead, the other (collected in 1911) was alive, shed spores, and was air-dried on December 20

A pure culture was again obtained, and sporophores had developed by February 21, 1950, when the culture was dried This extended the longevity to 38⅙ years

On April 25, 1962, I opened two more tubes One tube contained a single piece of sporophore collected in October 1909 and freeze-dried in December 1910 Within 24 h of being moistened this sporophore was shedding spores On April 27, a spore print was obtained for preservation on a glass slide and the specimen cultured by allowing spores to fall on to plates of potato dextrose agar The specimen was then air dried and on May 1, through the kindness of Mr H Proom, of the Wellcome Research Laboratories, re-dried (in two pieces) *in vacuo* over phosphorus pentoxide at room temperature The other tube, similar to that opened by Bisby in 1949 contained two pieces of sporophore, one collected in 1909, the other in 1911 The 1909 piece was dead The 1911 piece was viable, shed spores, and cultures were obtained This specimen, too, was air-dried on April 27 and freeze-dried (in two pieces) on May 1 By May 14 cultures from both the living specimens had developed sporophores

These tests extend the longevity of the 1911 collection to 50½ years and that of the 1909 collection to 52½ years, which is probably a new world record

A particularly interesting feature is that it is the sporophore tissue which remains viable On being moistened the gills uncurl and hymenial activity revives to give a succession of normal spores which readily germinate Unfortunately, whether spores which had been freeze-dried for fifty years were viable was not tested

The Buller specimens tested by Bisby in 1945 and 1949 and then found to be viable were all dead when re-tested May 4–6, 1962, as was the 1935 specimen from the Herbarium of the Royal Botanic Gardens, Kew, found viable by Bisby in 1945

Eight of Buller's original series of tubes still remain to be opened

Psilotum triquetrum, Swartz in Basutoland

Psilotum triquetrum, Swartz (*Psilotum nudum* (L) Beauv) has been listed recently around Port St John's, Cape Province (Jacot-Guillarmod, A personal communication, 1961) and in Natal, where it occurs locally on the coast, in bush swamp and, rarely, on mud flats[1] Engler and others noted this plant in the Rain Forest, Victoria Falls, and I have seen it in Ghana, in the Aburi Botanic Garden, growing on a tree stump (1958) In a general discussion with the Rev J Gomes, O P, mention was made that a plant like *Psilotum* had been seen in the Roma Valley, Basutoland Dr F Zeylmaker, previously of this Department, had made an entry in the Herbarium (1959) of a specimen of *Psilotum triquetrum* without making a clear record of the locality Consequently, during an endeavour to 'rediscover' this plant, the Cave Sandstone on the eastern escarpment of the Roma Valley was explored and a single colony of eighteen fronds of *Psilotum triquetrum* noted The plant was found growing in a cleft in the rock-face in running water The water was richly mineralized leaving a coralline encrustation on the surface of the more mature fronds of the colony The plant showed all the usual features of angularity of the stems, distinct flattening in the initial dichotomy of the frond and erect growth form Most accounts of this genus state that it is distinctly tropical and almost certainly epiphytic Manton[2] comments on its establishment in certain botanic gardens and greenhouses in non-tropical areas The climate of Basutoland is certainly not tropical, hence the observation of *Psilotum* growing here, particularly in a well-established non-epiphytic habitat, is worthy of record

Specimens of the Basutoland plant have been deposited in the British Museum (Natural History)

A Vegetative Method for producing Virus-free Nucellar Citrus Budwood

To reduce the hazard of virus diseases in citrus-developing areas it is commonly recommended that only budwood of nucellar origin be used for multiplication purposes

Nucellar budwood is normally obtained from certified seedling trees In countries where these are not yet available their establishment is tedious, expensive and slow due to the long delay before budwood is produced for extensive budding It is thought that a quicker method could be adopted by using grafted nucellar plants instead of seedling plants, the former coming to maturity earlier and thus permitting an early varietal identification This is necessary, as in rare cases polyembryony may not be of nucellar nature but may originate by scission of the sexual embryo and the resulting seedlings are likely to differ from the parent

A method is described here for producing vegetatively propagated virus-free parent material in a relatively short time

Raising scion and rootstock seedlings Scion and rootstock seedling plants are raised under glass-house conditions Seed is sown in a sterilized compost mechanically consolidated into blocks, the compost consisting of three parts of soil to one of sand Standard mechanical analysis of a soil suitable to be composted and consolidated is as follows (per cent)

Clay and silt	15
Fine sand	70
Coarse sand	15

Two seeds are sown per soil block, but only one seedling is allowed to grow after germination The soil is watered as necessary and preventive pesticides should be applied

Approach grafting scion and rootstock seedlings Two months after germination both scion and rootstock seedlings should be approximately 15 cm high and approach grafting can be carried out The two stems are defoliated up to 10 cm from ground-level, and a 1 5–2 cm long cut is made in them at a height of 5 cm This cut should expose bark, phloem and xylem for

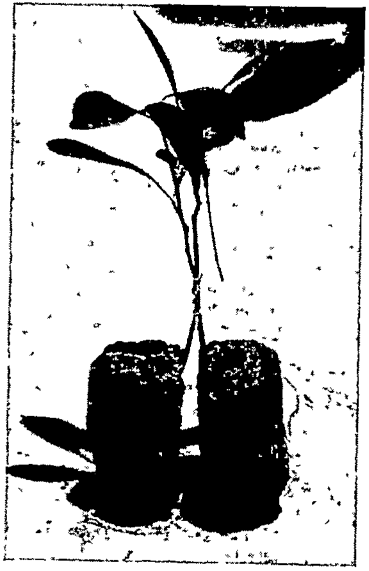

Fig. 1. Approach grafting scion and rootstock seedlings

half the stem thickness. Each soil block has one side removed and the two cut surfaces are placed in contact so that the two stems are close together. The two exposed surfaces in the stems are firmly tied together with sterile material (Fig. 1).

Scion and rootstock seedlings so treated are potted, and three weeks after grafting the rootstock seedling is topped 1 cm. above the graft union. The scion seedling is cut 1 cm. below the graft union four weeks after grafting and its roots are removed from the pot. Tying materials and the stub above and below the union should also be removed four weeks after grafting.

Although the method described proved successful under normal daylight conditions, the union of the two plants and the subsequent growth of the graft were faster under an artificial light supply of 18 h. a day.

Long-Distance Migration of Salmon

In 1956 a salmon tagged in Scotland was recaptured in Eqaluq Fjord, south of Sukkertoppen, on the west coast of Greenland[1]. Information about the recapture of a second British salmon has recently been received from the Ministeriet for Grønland. The more recent recapture was made on October 19, 1961, near Kangamiut (65° 50′ N., 53° 21′ W.), a small settlement north of Sukkertoppen and just outside the Arctic Circle. The fish was a male, 73 cm. overall and weighed 2.4 kgm. when gutted. It was tagged as a smolt approximately 20 cm. in length in the estuary of the River Usk, Monmouthshire, on April 27, 1960. The distance between tagging and recapture positions is about 2,000 miles.

This recapture is of especial interest because the smolt was one of a number which entered the cooling-water system of the Uskmouth Generating Station, near Newport, Monmouthshire, and were netted out of the fine screen chambers, tagged and released lower down the estuary in the course of the rescue operations organized by the Central Electricity Generating Board.

In 1960 a salmon tagged as a smolt in the estuary of the Miramichi River, New Brunswick, Canada, was recaptured on the south-west coast of Greenland[2], and more recently the recapture of another Canadian salmon in that area has been reported (Nielsen, J., private communication).

Large numbers of salmon, both smolts and adults, have been tagged during recent years, and it is possible that these very-long-distance migrations may be more common than was earlier supposed. Whether fish that have travelled so far would normally return to their native rivers to spawn is, of course, still unknown. However, these recent reports show that salmon from both sides of the Atlantic can appear together in the coastal waters of south-west Greenland at some stage during their marine life.

We thank Dr. Jørgen Nielsen, of the Ministeriet for Grønland, Charlottenlund, Denmark, for supplying details of this recapture.

ENTOMOLOGY

Influence of Illumination on Moulting and Regeneration in the Cockroach *Blattella germanica* (L.)

In *Blattella germanica*, at temperatures between 18° and 30° C., regeneration of a metathoracic leg, if begun before the critical period, adjusts the moulting cycle so as to provide the exact amount of extra time needed for completion of the regeneration process before ecdysis[1-4]. (If the level of regeneration is such as to require no muscular reorganization, this effect is absent[5-7].) In animals regenerating a whole leg, but not in controls, the corpora allata and 'head lobes' (ventral glands) show marked volume oscillations suggesting a circadian rhythm[5,11]. Photoperiod effects are important in re-setting timing of developmental processes in the diapause of many insects[8], and the onset of the dark phase in particular influences circadian activity rhythms, neurosecretion, and abnormal morphogenesis leading to tumour formation in the cockroach *Periplaneta*[9]. Far-red illumination has an adverse effect on growth in *B. germanica*[10].

Time-regulation of the temperature-dependent moulting and regeneration processes may involve some temperature-independent factors such as illumination. Preliminary to a study of possible photoperiod effects, an investigation of the influence of single changes in illumination on moulting and regeneration has been made.

Mass-cultures of *B. germanica* were reared for at least two generations in a 'light box' continuously illuminated by a fluorescent daylight lamp (40 W , correction factor 0 91) giving a light intensity in the cultures of 70–75 foot-candles (*L*-series), or in a similarly constructed 'dark box' in continuous total darkness (*D*-series) In both boxes, constant conditions of 29° ± 0 5° C , 60–70 per cent relative humidity were maintained Ootheca-bearing females were isolated, and the progeny of each divided into 4 groups of 6–10 individuals In groups I and II, the left metathoracic leg was removed at the same known age, while groups III and IV were controls Groups I and III were kept in the conditions in which they had been reared, while groups II and IV were transferred, at the time of removal of the leg, to the alternative conditions (that is, *L*-series to dark box, *D*-series to light box) A total of 1,850 *D*-series animals was used, treated at 0, 1, 2 and 3 days old and on days 1 and 3 of instar II Because of much higher mortality, the *L*-series yielded only 420 animals in the same period, these were treated at 0, 1 and 2 days old

24-hourly inspections yielded a comparison between the mean ages at ecdysis of regenerating and control animals kept in darkness and their sibs transferred to constant light, and vice versa All were necessarily exposed during inspection, between 3 and 6 p m each day, to diffuse room lighting for about 30 min and to intense light under the microscope for about 1 min This regular brief interruption of constant darkness régimes is unlikely to have been significant (the light phase is unimportant in entraining photoperiod-controlled circadian rhythms in *Periplaneta*[9])

The results (Tables 1 and 2) show a similar relation between regeneration and the moulting cycle to that already reported Transfer from light to darkness accelerates ecdysis and vice versa, but neither transfer affects regeneration as such Effects are marked only if transfer is made during a photosensitive period shortly after hatching or ecdysis, in instar II, but not instar I, there is some evidence of a recurrence of photosensitivity just after the critical period

Table 1 RETARDATION OF ECDYSIS IN *L*-SERIES MATERIAL TRANSFERRED TO DARK BOX AT AGES SHOWN IN FIRST COLUMN

Age in days at time of transfer	Difference (± S E), in days, between mean age at ecdysis of animals transferred to dark box and that of their sibs kept in constant light		
	Unoperated controls	Operated animals producing a Papilla	Operated animals producing a Regenerated leg
0–1	+0 5 (±0 095)	none recorded	+0 8 (±0 123)
1–2	−0 04 (±0 1)	none recorded	+0 2 (±0 095)
2–3	+0 05 (±0 18)	+0 12 (±0 26)	+0 33 (±0 31)

Table 2 ACCELERATION OF ECDYSIS IN *D*-SERIES MATERIAL TRANSFERRED TO LIGHT BOX AT AGES SHOWN IN FIRST COLUMN

Age in days at time of transfer	Difference (± S E), in days, between mean age at ecdysis of animals transferred to light box and that of their sibs kept in constant darkness		
	Unoperated controls	Operated animals producing a Papilla	Operated animals producing a Regenerated leg
0–1	−0 6 (±0 085)	none recorded	−0 8 (±0 085)
1–2	−0 2 (±0 085)	none recorded	−0 1 (±0 07)
2–3	−0 2 (±0 082)	+0 1 (±0 19)	−0 15 (±0 085)
3–4	+0 02 (±0 04)	−0 15 (±0 094)	none recorded
First day of instar II	−0 6 (±0 125)	none recorded	−0 5 (±0 11)
Third day of instar II	−0 2 (±0 09)	−0 5 (±0 16)	−0 2 (+−0 13)

In 4 *D*-series and 1 *L*-series batches which were followed through to metamorphosis, with the operated animals undergoing repeated regeneration, the 2nd and 3rd ecdyses were almost synchronous in both boxes, and the later ones somewhat delayed (not accelerated) in the light box, to which supermoulting by regenerating animals was confined The accelerating effect of light and the retarding effect of darkness are therefore not cumulative, the effective stimulus seems to be the change from dark to light or vice versa

Evidence[3] that regeneration virtually sets up a new moulting cycle needs re-interpreting in the light of the present results, which show no indication that the photosensitive phase of the normal cycle is repeated in regenerating animals Even those operated on at 0–1 day old merely show an 'excess' delay in moulting comparable with that originally reported[1,4] This may be due to shortage of neurosecretion to trigger the endocrine system, it does not appear in the corpora cardiaca until 24–48 h after hatching[11]

In *Periplaneta*, the circadian activity rhythm is undetectable just after moulting, when neurosecretion in the allato-subœsophageal nerve is minimal[8] In *B germanica*, the period of sensitivity of the moulting cycle to change of illumination coincides with a low level of (visible) neurosecretory activity Transfer to light or darkness may affect the moulting cycle by influencing the production or transport of neurosecretion and perhaps also modify the endocrine rhythm Further experiments, using photoperiodic as well as single illumination changes, and measuring the circadian activity rhythms, may elucidate these problems

Houseflies Resistant to Organic Phosphate in Australia

DDT resistance in the housefly (*Musca domestica* L) has been known in Australia since 1950[1] In addition, 'Dieldrin' resistance was recorded as early as 1956 (Shanahan and Wright, personal communication) During the past year, resistance to organic phosphate has occurred on both the east and west coasts of Australia

In November 1960, a report from Perth, Western Australia, suggested that larvæ feeding in manure heaps was resistant to a 'shotgun mixture' of DDT, 'Dieldrin' and 'Diazinon' following 3 years successful control Shortly after, a report was received that 'Diazinon' was losing efficiency in controlling houseflies in an abattoirs-effluent disposal area at Casino in northern New South Wales However, control could still be achieved by applying 'Diazinon' more frequently

Samples of larvæ were collected from both areas, and laboratory strains established and afterwards tested for resistance A reference strain was also established from adult flies caught in the Royal Botanic Gardens, Sydney Contrary to expectations it was completely resistant to type I and II chemicals[2] These flies may have originated from areas with a history of DDT and BHC treatments The reference strain was not resistant to organic phosphates Practically all flies in the Perth and Casino strains were found to be homozygously resistant to the ethyl-*O*-phosphate group within the organic phosphate insecticides, but were not resistant to the methyl-*O*-phosphate group[3]

The insecticide was applied in risella oil or kerosene to the thorax of 4–5 day-old female flies anæsthetized with carbon dioxide After treatment, the results of which appear in Table 1, the flies were kept for 24 h at 25 5° C At the higher concentrations of DDT 10 per cent acetone was added to the kerosene to assist in dissolving the insecticide

Table 1 TOXICITY OF SOME INSECTICIDES APPLIED TO THREE STRAINS OF *M* *domestica*

Insecticide	LD_{50} (μg/female) Sydney	Perth	Casino
Diazinon	0 056	0 50	0 48
Parathion	0 014	—	0 148
Bayer 21/199	0 08	—	0 43
Malathion	0 40	—	0 50
DDT	> 40	> 40	> 40
γ-BHC	0 94	1 0	0 95

Susceptible flies were unavailable for comparison but the LD_{50} levels of DDT and γ-BHC in Table 1 are such that on comparison with previously reported tolerances of susceptible strains there is no doubt that each strain is significantly resistant to these chemicals

Although it is usually accepted that selection with organic phosphate insecticides alone can confer cross-resistance to chlorinated hydrocarbons There was probably adequate use of DDT and BHC at Perth and Casino for the development of DDT and BHC resistance Both phosphate-resistant strains gave every indication, by the discriminating dose technique of Milani[4,5], that they were homozygously resistant to DDT and γ-BHC as well as 'Diazinon'

Hybridization experiments between the Sydney and Perth strains to test the inheritance of resistance in the Perth strain were undertaken Openoorth[6], and Nguy and Busvine[7] have already shown that 'Diazinon'-resistance in the housefly is due to a single fully dominant gene A dose known to discriminate against susceptibles, applied to F_2 flies (interbred F_1 from a resistant by susceptible cross), gave a 3 1 (*R*/*S*) ratio When the F_1 flies were back-crossed to the susceptibles, a 1 1 ratio resulted tending to confirm the results of the earlier workers In addition, resistance to 'Diazinon' has been held through six back crosses to the Sydney strain, which in itself is strongly indicative of a simple mode of inheritance[8]

Duration of Life, Egg Number and Parthenogenesis in the Stick Insect *Orxines macklotti* De Haan

IN the Phasmoptera bisexual and parthenogenetic reproduction both occur In several species males have never been found, or appear to be extremely scarce Some observations under natural conditions and many in captivity have established that the reproduction of these species is parthenogenetic and thelytokous[1–6] Well-known examples of this group are *Carausius morosus* Br from India, and the south European populations of *Bacillus rossii* F and *Clonopsis gallica* Charp

On the other hand, in species where males are common and where, at least in captivity, copulations have frequently been observed, parthenogenetic reproduction was found to lead to abnormalities in developmental processes It has been stated[4] that in a species of the genus *Leptynialla*, which has about 65 per cent males in natural conditions, only 3 per cent of parthenogenetically produced eggs hatch , the same author reports a 'weakening' of the third parthenogenetic generation in *Eurycnema* The development of unfertilized eggs of *Clitumnus extradentatus* Br takes about 2–3 weeks longer than that of normal ones[5] The following is another example of the biological significance of bisexual reproduction in a species of stick insect in which males are frequent

The species concerned, *Orxines macklotti* De Haan, was bred in large cages in the laboratory at an average temperature of about 24° Celsius and a relative humidity of about 90 per cent The insects were fed with *Rhododendron* leaves Further information on breeding and a description of some aspects of the behaviour of *Orxines* in captivity have already been given[7,8] When breeding *Orxines* in normal populations the sex ratio remains roughly 1 1 and copulations are very often seen

Table 1 HISTORY OF TEN NORMALLY AND TEN PARTHENOGENETICALLY REPRODUCING FEMALES OF THE WALKING STICK *Orxines macklotti* DE HAAN, AND OF THEIR OFFSPRING

Parents			Offspring				
Beginning of oviposition	Copulations	Females died	No of eggs	1st larva	% hatched	Sex ratio M F	Further breeds
About mid-November, 1957	Yes	1st individ on 3rd Dec 1957 , rest between 12th Febr and 1st May, 1958	1,673	March, 21st, 1958	81	1 1	Normal
About mid-November, 1957	No (No males in cage)	1st individ on 6th Febr 1958 , rest between 2nd May and 24th August, 1958	1,845	May 2nd, 1958	4 4	1 80*	20 of these 80 female larvæ reached adulthood, and laid 300 eggs, none of which hatched

* Absolute numbers

In late summer 1957 about 50 medium-sized, distinctly female larvæ were taken from the mixed populations and brought together in one cage. In the beginning of October two groups of ten larvæ from this purely female stock were put into two separate cages. Care was taken that all larvæ were of the same size (age). To the first group an ample number of males was added, as soon as the first larvæ had reached adulthood; copulations were often seen here. The second group remained without males. None of the eggs produced here can have been fertilized. Both groups began egg laying about mid-November. Table 1 shows how much the further history of the two groups differs.

Biosynthesis of Cholesterol in an Insect, Silverfish (*Ctenolepisma* sp.)

MUCH nutritional[1-4] and biochemical[5,6] evidence suggests that the insects, as a phylum, are incapable of synthesizing sterols. This biosynthetic deficiency results, in general, in a dietary requirement of insects for some sterol without which they cannot grow to maturity. The apparent capacity of two species to thrive on a sterol-free diet has been shown to reflect the sterol-synthesizing activity of their intestinal micro-organisms which supply sterols (as well as vitamins of the B group) in quantities sufficient to satisfy the insects' growth requirements[7]. Similarly, in the cockroach, *Blattella germanica*, incorporation of dietary [1-^{14}C] acetate into sterol, which occurs under non-aseptic conditions, has been shown to be almost entirely abolished in insects reared aseptically[6]. It has been shown that the sterol synthesis observed in this insect under non-aseptic conditions is due to initial synthesis of ergosterol by the intestinal flora, followed by the conversion of this compound to 22-dehydrocholesterol in the tissues of the insect. The rate of formation of 22-dehydrocholesterol by this process is, however, not sufficient to render the cockroach independent of a supply of sterol in its food[8].

In the course of these experiments with *Blattella*, it was noted that even in insects reared aseptically, so that the biosynthesis of ergosterol and 22-dehydrocholesterol was abolished, there was a small, though significant synthesis of cholesterol itself. Evidence for this was the incorporation of very small amounts of dietary [1-^{14}C] acetate into cholesterol in the total absence of its incorporation into 22-dehydrocholesterol. The possibility had been suggested previously[5] that the most primitive insects may retain the capacity to synthesize sterols, in contrast to the higher forms in which this capacity has been lost in the course of evolution. According to this view, the trace of cholesterol synthesis observed in the sterile cockroach might represent a residuum of cholesterol-synthesizing capacity which might be quantitatively more important, and, therefore, more amenable to study, in species of insects lower in the evolutionary scale.

In order to examine this question further, we have undertaken a study of the sterol metabolism of the silverfish, *Ctenolepisma* sp., an insect more primitive than the cockroach. Some preliminary findings are reported here.

The silverfish used in the experiments to be described were non-sterile insects at various stages of growth which had been trapped in the laboratory. A group of 24 such insects were maintained for 7 months under ordinary laboratory conditions of temperature and humidity with a food supply which consisted of 1 gm. dog food containing 1 mgm. sodium [1-^{14}C] acetate (25×10^6 c.p.m.) and drinking water supplied in a soaked cotton plug. At the end of this period, the insects were extracted in turn with hot ethanol, acetone, and ethyl acetate. The total lipid extract so obtained contained 60,000 c.p.m. This low level of incorporation of acetate was due to the very small overall food consumption of the insects which were prone to cannibalism. The dried, extracted residue weighed 100 mgm. Hydrolysis of the lipid extract with 10 per cent potassium hydroxide in methanol/water, 4:1, yielded a non-saponifiable fraction containing 10,000 c.p.m. This material was combined with 5 mgm. pure cholesterol and chromatographed on deactivated alumina[6] with recovery of the sterol fraction which contained 8,000 c.p.m.

The sterol was acetylated and the major portion (6,500 c.p.m.) was subjected to careful chromatography on 7 gm. Woelm alumina deactivated with 3 per cent of its own weight of 10 per cent aqueous acetic acid. Elution with pure hexane in 9 ml. fractions yielded a single peak of material extending from fraction 35 to 74, which contained 6,000 c.p.m. and a total of 4.3 mgm. material. The peak of radioactivity coincided with the peak of weight in this chromatogram and no significant radioactivity was recovered from the column in a further 95 fractions of hexane.

These conditions of chromatography have previously been shown to give complete separation of cholesteryl acetate from 22-dehydrocholesteryl acetate and ergosteryl acetate[6,9]. Coincidence of weight and radioactivity curves in the present experiments is therefore good evidence for the identity of the labelled material with cholesteryl acetate and for the absence of 22-dehydrocholesterol from the tissues of this insect. To confirm that the labelled sterol was indeed cholesteryl acetate, 2.9 mgm. of this material (4,000 c.p.m.) was mixed with 37.1 mgm. non-radioactive, pure cholesteryl acetate. The resulting material, with a specific activity of 98 c.p.m./mgm., was precipitated as the dibromide and the free sterol acetate regenerated by a modification of the method of Fieser[10]. The recovered recrystallized acetate (10 mgm.) had a specific activity of 96 c.p.m./mgm.

It is concluded that ingestion of sodium [1-^{14}C] acetate by the silverfish leads to the appearance of labelled cholesterol in the tissues of the insect. No 22-dehydrocholesterol was detected. If the appearance of labelled cholesterol is due to a primary synthesis of ergosterol by intestinal symbionts, then it follows that the silverfish, unlike the cockroach, is able to reduce the Δ^{22}-bond in the sterol side-chain and thus complete the conversion of ergosterol to cholesterol. The alternative possibility that the tissues of the insect itself can synthesize cholesterol is at least as reasonable in view of the fact that so large a percentage (about 10 per cent) of the total incorporated label of acetate is in the sterol fraction This is to be compared with a level of approximately 1 per cent of the total incorporation of carbon-14 which appears in 22-dehydrocholesterol in the non-aseptic cockroach and about 0 004 per cent in the aseptic cockroach A decision between these two possible explanations must await the outcome of further experiments which are in progress and will be reported in due course

MICROBIOLOGY

Reversal of Mitomycin c-induced Growth and Division Inhibition in a Species of *Erwinia*

MITOMYCIN *c*, an anti-tumour agent from culture filtrates of *Streptomyces caespitosus*, is effective against both Gram-positive and negative bacteria, and is bacteriocidal to growing and non-growing bacteria[1] It is an extremely potent inhibitor of growth and cell division of an *Erwinia* species, using a synthetic medium[2] normally supporting excellent growth

Growth inhibition can be partially overcome by increasing the concentration of one of certain divalent cations (calcium = manganese > magnesium > ferrous iron), or by increasing *p*H of the medium prior to inoculation Cobalt and zinc are inactive in overcoming growth inhibition, although zinc may reverse division inhibition to some extent Calcium, iron, manganese and zinc are in the basal medium in trace amounts , magnesium is at the level of 0 026 mgm / ml , in the form of magnesium sulphate

Increased levels of calcium or manganese partially reverse division inhibition caused by mitomycin *c* (0 2 μgm /ml), added iron or magnesium do not Neither added sodium chloride nor potassium chloride has any effect on growth or cell length in the presence of 0 2 μgm /ml of the antibiotic Representative data on the effects of various cations are given in Table 1

Increasing initial *p*H of the mitomycin *c* containing medium from 7 0 to 7 6 increases growth by a factor of 4–5, however division inhibition is not reversed Ammonium chloride and L-α-alanine, effective reversers of D-amino-acid induced division inhibition[2], do not reverse division inhibition caused by mitomycin *c*, although ammonium chloride overcomes growth inhibition to some extent

Table 1 EFFECT OF VARIOUS INORGANIC SALTS ON GROWTH AND CELL LENGTH OF *Erwinia* SP IN THE PRESENCE OF MITOMYCIN *c*

$MgSO_4$ 1 0 × 10^{-3}	0 4	0 23	60	38	2
$FeSO_4$ 2 7 × 10^{-4}	0 4	0 07	30	50	20

Optical density readings determined on a *B* and *L* Spectronic 20 spectrophotometer at 540 mμ, after incubation for 16 h at 25° C on a rotary shaker (ref 2)

Pantoic acid, pantoyl lactone, and sodium pantothenate (able to reverse growth inhibition and/or division inhibition caused by D-serine or penicillin[3]) do not reverse growth inhibition caused by mitomycin *c* However, pantoyl lactone effectively overcomes division inhibition, it is the only substance tested which produces a really significant degree of reversal In general, the spectrum of reversal of mitomycin *c* cell division inhibition, with this species of *Erwinia*, resembles that of penicillin[3] in many respects, particularly in that pantoyl lactone is the only really effective division inhibition reversing agent Results of the effect of organic compounds in the presence of mitomycin *c* are given in Table 2

In the presence of supplements of calcium, manganese, or magnesium (0 2 μgm mitomycin *c*/ml), pantoyl lactone or pantoic acid completely nullify the ability of the cations to stimulate growth Calcium may even enhance the slight toxicity of pantoyl lactone However, calcium enhances reversal of division inhibition by pantoyl lactone All three cations stimulate a certain degree of reversal of division inhibition by pantoic acid, a compound completely unable to reverse division inhibition in the absence of metal ion supplements

Pantoyl lactone, pantoic acid, and calcium chloride, which have the ability to trigger division of 12-h D-serine induced filaments, in the presence of D-serine[4], were tested in a similar manner with mitomycin *c*-induced filaments Since mitomycin *c*-induced filaments are, in all probability, deficient in DNA[5], it may be that, with such a deficiency, essential prior steps

Table 2 EFFECT OF CERTAIN ORGANIC COMPOUNDS ON GROWTH AND CELL LENGTH OF *Erwinia* SP IN THE PRESENCE OF MITOMYCIN *c*

Additive and *M* concentration	Mitomycin *c* (μgm /ml)	Optical density	Cell length (percentage in each range) 3–20μ	20–50μ	> 50μ
None	None	1 00	(70% 3–5, 30% 5–10)		
None	0 2	0 22	30	50	20
L-α-alanine 3 36 × 10^{-2}	0 2	0 14	80	20	
Pantoyl lactone 4 0 + 10^{-2}	0 2	0 14	(80% 2–5 20% 5–10)		
Pantoic acid 4 0 × 10^{-2}	0 2	0 14	60	30	10
α-ketoisovaleric acid 1 4 × 10^{-2}	0 2	0 23	55	40	5
Sodium-D-pantothenate 1 4 × 10^{-3}	0 2	0 17	40	40	20

Conditions for growth and measurement as given in Table 1 Pantoic acid was prepared by hydrolysing pantoyl lactone with an equimolar amount of sodium hydroxide for 10 min at 100° C for terminal division cannot occur We observed that mitomycin *c*-induced filaments did not divide nearly as readily as D-serine-induced filaments, although with pantoyl lactone or calcium chloride some division did occur Pantoic acid was inactive

Mitomycin *c* apparently causes damage of cell wall or membrane Supernatants from cultures grown in the presence of the antibiotic have a high 260/280 mμ absorbance ratio as compared with uninoculated medium indicating leakage resulting from damage to the osmotic barrier Lysis of cells occurs when mitomycin *c* is added to exponentially growing cultures

Mitomycin *c* depolymerizes DNA *in vivo* when tested with *Escherichia coli*[5] Much evidence exists that the mechanism of DNA breakdown *in vivo* is by means of the activation of a DNase, although *in vitro* activity of DNase from *E coli* is not stimulated by mitomycin *c*[6] Reich *et al* [5] state that magnesium is needed for an optimal depolymerization of DNA, in view of this it would be expected that increased magnesium concentrations would enhance, rather than diminish, mitomycin *c* growth inhibition It is possible that with this *Erwinia* species the optimum concentration for magnesium activation of DNase is exceeded at levels of magnesium which reverse growth inhibition If this were true, the mechanism of growth inhibition by mitomycin *c* would involve some factor other than activation of DNase On the other hand, a certain concentration of magnesium (or other divalent cation) may serve to stabilize the DNA molecule, as it has been shown to do with RNA from yeast[7], or tobacco mosaic virus a calcium–magnesium co-ordination complex[8]

The differential effects on growth and cell division by the various agents reported here indicate that the action of mitomycin *c* on *Erwinia* cannot be explained completely in terms of scission of preformed DNA The relationship of the known action of mitomycin *c* on DNA to its effects with *Erwinia* obviously requires further scrutiny

This investigation was supported by grant *G*9848 from the U S National Science Foundation We wish to thank Dr R D Coghill National Institutes of Health, for a gift of mitomycin *c*

Taxonomy of the Fish Furunculosis Organism

RECENTLY, Vickers and McClean[1] described cases of fish furunculosis in Lough Neagh pollan, *Coregonus pollan* Thompson They have named the organism isolated *Bacillus salmonicida* (Emmerich and Weibel) This is erroneous, as revealed by the description of characteristics given Since the organism is Gram-negative, non-sporulating and able to ferment sugar to acid, it cannot belong to the genus *Bacillus*, which is defined as consisting of Gram-positive sporulating bacteria, obligate aerobe, with highly oxidative metabolism The furunculosis organism was discovered by Emmerich and Weibel[2] in 1894 and described as *Bacterium salmonicida* This name has been in general use[3–6] until in recent years when the organism was incorporated in the new genus *Aeromonas* Kluyver and Van Niel[7,8]

The description of biochemical properties of the organism isolated by Vickers and McClean[1] conforms with the official descriptions, except its lack of indole production The regular strains should produce indole in broth cultures, but not hydrogen sulphide However, although this is an important difference from the *forma typica*, it is not enough to separate the organism from the species *Aeromonas salmonicida*, belonging to the family Pseudomonadaceae of the Eubacteriales

VIROLOGY

Echo Virus Type 23 (Williamson) in Monkey Kidney Tissue Culture

THE cytopathic effect produced by *Echo* virus type 23 in rhesus monkey kidney tissue culture has been unsatisfactory, where propagation in this system has been accomplished[1,2], certain disadvantages made it necessary that an easier and less complicated method be devised for the regular detection of growth of this viral agent

This report describes some improvements in the technique of the propagation of *Echo* 23 in rhesus monkey kidney tissue culture and its application in the optimal dilution (checker board) neutralization test

Rhesus monkey (*Macaca mulatta*) kidney tissue culture tubes and bottles were prepared as previously described[3] in Eagle's growth medium with 5 per cent calf serum (*p*H 7 0) After eight days growth and just before virus was inoculated growth medium was removed, the cells were washed twice with phosphate-buffered saline and 0 1 c c and 1 0 c c of 10^{-1} dilution of *Echo* 23 (Williamson) was inoculated into tubes and milk dilution bottles respectively After 15–20 min 1 0 c c and 10 0 c c of Sabin's maintenance medium consisting of 5 per cent lactalbumin hydrolysate in Earle's solution with 0 22 per cent sodium bicarbonate, *p*H 7 5 was added either to tubes (1 0 c c) or bottles (10 0 c c) Control tissue culture tubes and bottles were treated in the same way as infected cultures, except that phosphate-buffered saline in the same volumes as those inoculated with tubes and bottles was added instead of virus

In order to check the specificity of virus obtained by serial passage, an optimal dilution neutralization test was carried out on the 7th and 8th passaged stock with anti-*Echo* 23 monkey serum[3] The test consisted essentially of mixing equal volumes of every dilution of virus in phosphate-buffered saline (10^{-1}–10^{-6}) with every dilution of uninactivated serum (1 · 1,024–1 256,000) in phosphate-buffered saline The mixtures were incubated in a 37° C water bath for 1 h 0 1 ml of each mixture was then inoculated into each set of six tubes devoid of growth medium and washed with phosphate-buffered saline This was followed 15–20 min later with 1 5 c c of Sabin's maintenance medium Incubation of the test was at 37° C and tubes were examined microscopically for cytopathogenicity daily for seven days

The cytopathic lesions of *Echo* 23 are typified in the early phase by rounded or ovoid cells in grape-like clusters and with clear cytoplasm and refractile edges usually at the periphery of the cell sheet As more virus is produced the whole periphery of the cell sheet shows this typical degeneration, and occasionally similar clusters of rounded cells are found in the centre of the cell sheet The cytopathic effect usually begins 24–36 h after infection Cellular destruction is usually not complete

Table 1 FINAL DAY (7) READING OF AN OPTIMAL DILUTION NEUTRALIZATION TEST WITH *Echo* 23 IN MONKEY KIDNEY TISSUE CULTURE

Virus dilutions	Antiserum dilutions* 1,024	4,096	16,384	65,536	262,144	Controls *PBS*	*NMS* 1,024
10^{-1}	0/6	0/6	0/6	6/6	6/6	3/3	4/4
10^{-2}	0/6	0/6	0/6	6/6	6/6	4/4	4/4
10^{-3}	0/6	0/6	0/6	2/6	6/6	4/4	4/4
10^{-4}	0/6	0/6	0/6	0/6	6/6	2/4	4/4
10^{-5}	0/6	0/6	0/6	0/6	0/6	0/4	2/4
10^{-6}	0/6	0/6	0/6	0/6	0/6	0/4	0/4
PBS	0/4	0/4	—	—	—	—	0/4

Inoculum 0 1 c c of virus–serum mixture

* Reciprocals of dilutions

Numerator, No showing cytopathic effect, denominator, total tubes per dilution mixture

NMS, Normal monkey serum, *PBS*, phosphate-buffered saline

The results of a typical optimal dilution neutralization test with this virus are shown in Table 1 By this method it has been possible to determine the TCD_{50} of the virus and the neutralizing titre of the serum without first resorting to a separate titration test for the virus, and then determining the neutralizing titre of serum in another test Conventional neutralization test on *Echo* 23 using the same serum as above and 100 TCD_{50} virus gave an *SDE* of 1 65,536 So far we have been able to maintain serial passages (11 passages) of *Echo* 23 in monkey kidney tissue culture without loss in infectivity

The *Echo* virus (Williamson) was kindly supplied by Dr Albert B Sabin

This work was supported in part by a U S Public Health Service research grant *C*–6006, from the National Institutes of Health

Monkey Pox Disease in Irradiated Cynomologous Monkeys

A POX-LIKE infection was observed in a female cynomologous monkey (*B*-39) approximately 45 days following exposure to whole-body irradiation of 350 r Monkey *B*-39 had been maintained in the same area for approximately ten months and was one of the eight survivors of a group of monkeys used in a series of irradiation studies All were apparently free from any noticeable infection until the appearance of the pox lesions Similar pox lesions were seen in one other irradiated monkey (*B*-44) in an adjacent cage a few days later

Clinical lesions similar to those described by von Magnus *et al* [1] and Prier and Sauer[2] were observed These lesions included pox-like skin eruptions, severe facial and cervical œdema, hæmorrhagic ulcerations, dyspnœa, and bloody diarrhœa Both infected monkeys died twelve days following the outbreak of the disease Only one non-irradiated monkey (*C*-302) became infected with the agent This monkey had cervical œdema and ulcerated areas on the arms and forehead similar to the lesions seen in the other two animals (*B*-39 and *B*-44), however, this animal survived the infection No signs of infection were seen in the remaining survivors of the irradiation study, nor in the 19 other non-irradiated monkeys that were housed in the same room

Virus isolation was attempted from scabs obtained from the thigh area of monkey *B*-39 An agent which produced a cytopathogenic effect in monolayers of monkey kidney epithelial cells was isolated Transmissibility was established by serial passage of the isolate in monkey kidney tissue culture and in rabbit kidney tissue culture The appearance of a typical cytopathogenic effect (Figs 1 and 2) was used as the criterion for virus multiplication First, monkey

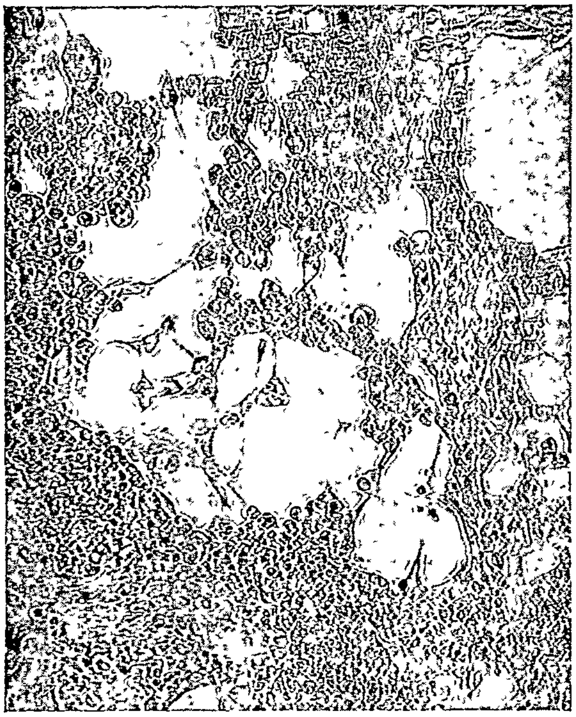

Fig 1 Cell destruction in monkey kidney epithelial cells infected with 'monkey pox agent' four days post infection (× 104)

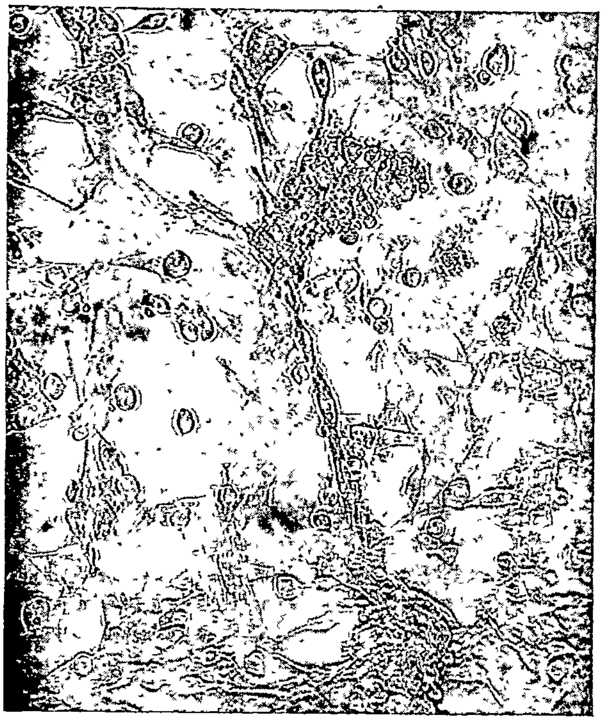

Fig 2 Cell destruction in rabbit kidney epithelial cells infected with 'monkey pox agent', five days post infection (× 104)

kidney tissue fluid containing the isolate when inoculated on the chorioallantoic membrane of 13-day-old embryonated eggs produced lesions with considerable necrosis and hæmorrhage A 20 per cent suspension of the infected membranes in physiological saline solution hæmagglutinated susceptible chicken red blood cells with a titre of 1 128 Two hæmagglutinating units of antigen were inhibited by 1 640 dilution of hyperimmune vaccinia rabbit serum which had been adsorbed with chick red blood cells The agent was then classed as a member of the variola-vaccinia group This agent was not neutralized in tissue culture by herpes *B* (Herpes simae) hyperimmune serum

Animal inoculation techniques differentiated the isolate from variola Death resulted in 3-week-old mice when inoculated intracranially, but not when inoculated intraperitoneally as reported previously by Prier *et al*[3] The agent was successfully passed serially in the epidermis of adult rabbits, thus differentiating it from variola[4]

A serological survey of our monkey colony was conducted at this time to determine the number of monkeys with detectable hæmagglutination-inhibition antibody to the isolated agent The results are given in Table 1

Table 1 SEROLOGICAL SURVEY OF MONKEY COLONY FOR MONKEY POX VIRUS

Species of monkey	No exposed to irradiation	No with clinical monkey pox disease	Hæmagglutination inhibition titres			
			0 titre	1 10– 1 40	1 80– 1 640	1 1,280 and higher
Cynomologous	Irradiated 8	2	2 *N D*	1	5	0
	Not irradiated 22	1	1	1	18	2
Cynomologous*	Not irradiated 45	0	30	10	4	1
Rhesus	Not irradiated 67	0	9	6	46	6
African green	Not irradiated 14	0	4	4	6	0

N D, Not done

* Monkeys not in area of occurrence of monkey pox disease

The room in which the monkey pox disease occurred showed 89 3 per cent of the 28 cynomologous monkeys to have a significant hæmagglutination inhibition titre of 1 80 and higher The highest hæmagglutination inhibition titres, 1 2,560 and 1 1,280, were found respectively in the serum of the non-irradiated cage mate (*B*-38) and in the convalescent serum of the non-irradiated infected monkey (*C*-302) In contrast only 11 per cent of the 45 cynomologous monkeys caged in other separate rooms showed significant hæmagglutination inhibition titres One cynomologous monkey out of this total had a high (1 1,280) hæmagglutination inhibition titre, while 30 were without titres and 10 had titres of 1 40 It is interesting to note that 77 5 per cent of the 67 rhesus monkeys had hæmagglutination inhibition titres of 1 80 and higher

From the results obtained, it would appear that the monkey pox virus may be carried by some species of monkeys as a latent virus Irradiation, by decreasing host resistance, may lead to the appearance of clinical disease Other monkeys can then acquire the disease clinically or, more likely, sub-clinically

Airborne Transmission of Influenza Virus Infection in Mice

THE mode of transmission of influenza has been the subject of great controversy[1] Human volunteers can be experimentally infected by dropping infected fluids into the nasopharynx[2], by inhalation of finely atomized liquid suspension[3], or by inhalation of room air into which virus has been introduced by aerosol spray[4] However, there is no direct evidence to prove whether epidemic or pandemic influenza is spread by direct contact by large droplets, or by finely dispersed airborne droplet nuclei

Indirect evidence of airborne transmission was found by McClean[5], in an examination of a hospital unit equipped with ultra-violet irradiation The incidence of influenza was lower among patients housed in the irradiated unit than among patients housed in a non-irradiated unit

Direct experimental evidence showing that ferrets could transmit influenza virus infection by the airborne route has been given by Andrewes and Glover[6]

A model has been developed in this laboratory for the study of transmission of influenza virus infection in mice Mice are infected with influenza virus by exposure to an aerosol spray of *A*2 (Asian) virus We have found that infected mice transmit influenza virus to non-infected animals almost exclusively during the period 24–48 hr. after the initiation of their infection[7].

Twenty-four hours after initiation of their infection, mice were placed in a wire mesh cage inside a modified autoclave chamber. Non-infected mice were placed in the same cage, but were separated in two of the four experiments from the infected animals by a double mesh wire screen that assured at least a ¾-in. separation. A 24-hr. exposure period was allowed under conditions of measured air-flow through the chamber. At the end of this period the previously uninfected mice were quarantined for a 48-hr. period in separate individual cages. The lungs of these previously uninfected animals were then tested individually for the presence of virus by inoculation of a 10^{-2} dilution of ground lung suspensions into 10–13-day-old chick embryos.

The fundamental factors involved in the transmission of respiratory infections have been defined by Wells[8] as follows:

$$C = r \times I \times S$$

where C = the number of new cases, I = the number of infectors, S = the number of susceptibles, and r = the effective contact-rate.

Table 1. INCIDENCE OF TRANSMITTED INFECTION AT VARYING RATES OF AIR-FLOW

C	r	I	S	V
16	0·0727	11*	20	2·3 l./min.
12	0·0600	10*	20	2·3 l./min.
7	0·0233	6	50	6 l./min.
2	0·0067	6	50	30 l./min.

C, No. of previously uninfected animals with demonstrable pulmonary virus; r, effective contact-rate; I, No. of infectors; S, No. of susceptibles; V, air-flow through the chamber (l./min.).

* Infectors and susceptibles separated by double mesh wire screen.

It was possible in four separate experiments to determine values for each of these factors at varying rates of air-flow (V) through the chamber. As illustrated in Table 1, the effective contact-rate (r) was inversely proportional to the rate of air-flow through the chamber, the greater the air-flow, the lower the effective contact-rate. When the values for r are plotted logarithmically against those of V a nearly straight line relationship is obtained.

We believe that the profound effect of varying air-flow-rates on the rate of transmission can best be explained by the conclusion that mice transmit influenza virus infection almost exclusively by airborne droplet nuclei. Droplet nuclei, because they are dispersed in the air, must obviously be reduced in concentration as the environmental air-flow is increased. The chance of acquiring airborne infection is thus inversely related to the ventilation[8,9]. It is notable that in experiments with ferrets[6], Andrewes and Glover found that a fan providing rapid air-flow diminished the transmission of influenza virus infection. We have also found that the rate of transmission when free intermingling of infected and contact mice is permitted is not appreciably different than when the two groups are separated by a double wire screen, an observation that supports the hypothesis of airborne transmission.

Measurements of the relative humidity inside the chamber were made during the exposure period, with values for different experiments ranging from 47 per cent to 70 per cent. The effect of air-flow (V) on the effective contact-rate (r) can be corrected by multiplying the two values. When the resulting product (rV) for each experiment is plotted against the relative humidity, the curve given in Fig. 1 is obtained. There is a significant decline in the product rV (and hence in r) as the relative humidity rises from 47 to 70 per cent. Hemmes *et al.*[10] and Harper[11] have shown that the decay-rate of airborne droplet nuclei of influenza virus increased rapidly as the relative humidity was raised from 40 to 70 per cent.

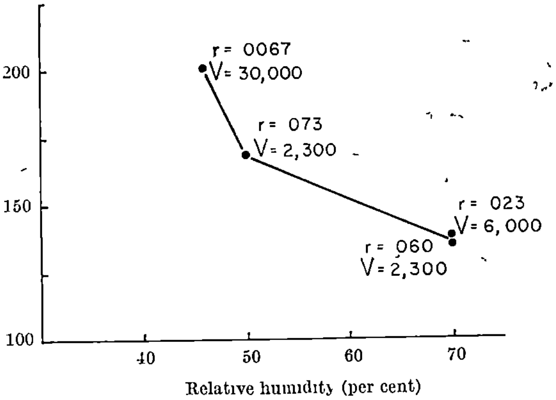

Fig. 1. Airborne transmission of influenza virus infection in mice. r, Effective transmission-rate; V, air-flow (c.c./min.)

The combined effects of increased ventilation and high relative humidity in decreasing the effective rate of transmission of influenza virus infection may, in part, explain the seasonal factors in influenza. The present investigations have demonstrated that the transmission of influenza virus infection in mice is enhanced by conditions of low relative humidity and diminished ventilation, conditions which correspond to the usual winter, indoor environment of man. However, recent preliminary studies have also suggested that seasonal factors may act directly on the mice affecting their ability to transmit influenza virus infection.

This work was carried out under the auspices of the Commission on Influenza of the Armed Forces Epidemiological Board and was supported in part by the Office of the Surgeon General and also aided by a grant from the National Tuberculosis Association—American Thoracic Society.

FORTHCOMING EVENTS

(*Meeting marked with an asterisk * is open to the public*)

Sunday, September 16—Saturday, September 22

International Union of Pure and Applied Physics (at Queen Mary College (University of London), Mile End Road, London, E 1)—Eighth International Conference on Low Temperature Physics

Monday, September 17

Institute of Metal Finishing (at Northampton College of Technology, St John Street, London, E C 1), at 6 15 p m —Mr M Clarke 'Porosity in Electrodeposited Tin"

Monday, September 17—Wednesday, September 19

Faraday Society (in the University Laboratory of Physiology, The University, South Parks Road, Oxford)—General Discussion on "High Resolution Nuclear Magnetic Resonance"

Monday, September 17—Friday, September 21

Conchological Society of Great Britain and Ireland, and the Malacological Society of London (at the British Museum (Natural History), Cromwell Road, London, S W 7, and Queen Elizabeth College (University of London), Campden Hill Road, London, W 8)—First European Malacological Congress

Tuesday, September 18

Institute of Fuel (at the Institution of Civil Engineers, Great George Street, London, S W 1), at 5 30 p m —His Excellency E N van Kleffens "The European Communities (E E C , E C S C , and EURATOM)", Mr S Nora "Energy in the Context of the European Communities" *

Tuesday, September 18—Friday, September 21

Battersea College of Technology, Department of Metallurgy (at Battersea Park Road, London, S W 11)—Materials Summer School—"Materials for Vessels and Containers for Low Temperatures"

First International Congress of Food Science and Technology (at the Imperial College of Science and Technology, South Kensington, London, S W 7)

Thursday, September 20

Institution of Mining and Metallurgy (at the Geological Society, Burlington House, Piccadilly, London, W 1), at 5 p m —General Meeting

Friday, September 21

Biochemical Society (in the Department of Biochemistry and Chemistry, The Medical College of St Bartholomew's Hospital, Charterhouse Square, London, E C 1), at 2 p m —Colloquium on The Teaching of Biochemistry to Medical Students"

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned

Research Assistants (2) (with a degree in an engineering or science subject, or equivalent qualification and knowledge of two modern foreign languages, preferably with library experience) in the Science Museum Library, for duties including classifying and cataloguing scientific and technical literature and preparing bibliographies—Civil Service Commission, 17 North Audley Street, London, W 1, quoting S/5540/62 (September 20)

Head (with suitable qualifications and experience to supervise teaching and ancillary staff and 150 students following a full-time pharmacy course) of the New Zealand School of Pharmacy—The High Commissioner for New Zealand, 415 Strand, London, W C 2, and the Principal, Central Institute of Technology, P O Box 177, Patone, New Zealand (September 21)

Assistant Lecturer or Research Demonstrator in the Physics Department—The Secretary, Queen Elizabeth College, Campden Hill Road, London, W 8 (September 22)

Lecturer (with a degree in biochemistry, organic chemistry, physiology or pharmacology, postgraduate research experience of Ph D or equivalent standard essential, preferably with an interest in the study of natural products or biosynthesis) in Biochemistry in the Department of Physiology and Biochemistry—The Secretary and Registrar, The University, Southampton (September 22)

Research Fellow (with research experience in solid-state physics or physical electronics, familiarity with ultra-high vacuum techniques desirable) in a surface physics group investigating mechanism of photoelectric emission—The Secretary and Registrar, The University, Southampton (September 22)

Lecturer or Assistant Lecturer in Bacteriology—The Registrar, The University, Leeds 2 (September 24)

Physicist, Basic grade (with a first- or second-class honours degree in physics) in the Physics Department, to assist with the routine, development and research work of the Department in the application of physics to medical problems—The House Governor, The London Hospital, Whitechapel, London, E 1 (September 24)

Assistant in Applied Economics in the Department of Social and Economic Research—The Secretary of University Court, The University, Glasgow (September 25)

Director of the Institute of Education—The Secretary, The University, Exeter (September 29)

Lecturer (registered medical practitioner with previous experience of the subject) in Chemical Pathology, for duties including teaching, research and hospital diagnostic routine—The Secretary, Royal Free Hospital School of Medicine, 8 Hunter Street, London, W C 1 (September 29)

Lecturer (preferably with a postgraduate science degree in pharmacology) in Pharmacology in the Department of Pharmacology and Therapeutics, Queen's College, Dundee—The Secretary of theUniversity of St Andrews, c/o Queen's College, Dundee (September 29)

Assistant Lecturer (with research experience in physical chemistry) in Physical Chemistry—The Secretary, Royal College of Science and Technology, Glasgow (September 30)

Lecturer (with a degree or equivalent qualification, and with appropriate teaching and industrial experience) in Electronics in the Department of Electrical Engineering, to teach electronics and allied subjects to post-H N C standard—The Principal, Reading Technical College, King's Road, Reading, Berks (September 30)

Lecturer or Senior Lecturer (non-medically qualified, preferably with interest and/or experience in immunological methods of hormone assay or hæmatological serology) in the Department of Obstetrics and Gynæcology—The Registrar, The University, Leeds 2 (September 30)

Research Assistant (university graduate, either a biologist with biophysical training or a physicist with biological interests) in the Wellcome Laboratories of Pharmacology, for investigations into the effects of hormones on the permeability of membranes—The Secretary of the University, College Gate, St Andrews (September 30)

Principal Scientific Officer or Senior Scientific Officer (honours graduate in animal husbandry or other appropriate science, with considerable research experience) in the Animal Studies Department, to work as the senior member of a team undertaking research into the nutrition of hill sheep and associated problems—The Secretary, Hill Farming Research Organization, 48 Palmerston Place, Edinburgh 12 (October 6)

Senior Assistant Librarian (graduate, with experience in librarianship, preferably in a university library)—The Registrar, The University of East Anglia, 4 Cathedral Close, Norwich, NOR16P (October 8)

Lecturer in the Department of Psychology—The Secretary, The University, Aberdeen (October 10)

Senior Laboratory Technician (M I L T or equivalent qualification), for the Ruakura Animal Research Station, New Zealand, for duties including assistance in biochemical studies of silage fermentation—The High Commissioner for New Zealand, 415 Strand, London, W C 2, quoting B 13/2/8 (October 11)

Lecturer in Philosophy at the University of Melbourne, Australia—The Secretary, Association of Universities of the British Commonwealth, Marlborough House, Pall Mall, London, S W 1 (October 15)

Lecturer in Physical Chemistry at the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S W 1 (October 15)

Reader (with a higher degree in electrical engineering, with experience in some aspect of electronics or communications and able to show evidence of experience in lecturing on theoretical topics to honours students and of ability to supervise and participate in research projects) in Electrical Engineering at the University of Queensland, Australia—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S W 1 (October 15)

Research Assistant (with appropriate research experience, preferably to Ph D level) in Chemistry, for work on the oxidation of cysteine peptides, the project programme involving both kinetic and isotopic tracer studies—The Secretary, The University, Exeter (October 15)

Senior Lecturer or Lecturer (with an interest in electrical communications) in Electrical Engineering at the University of the West Indies—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W C 1 (October 15)

Senior Lecturer in Pharmacology at the University of Melbourne, Australia—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S W 1 (October 15)

Senior Lecturer or Lecturer (with research and teaching experience in pharmaceutical chemistry, and preferably to have worked in the field of chemical mechanisms of drug action) in Pharmaceutical Chemistry at the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S W 1 (October 15)

Senior Lecturer in Social Anthropology at the University of Sydney, Australia, to assist in the organization of teaching and research in the Department of Anthropology and to supervise certain field projects—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S W 1 (October 15)

Chair of Pathology at the Medical College, University College of Rhodesia and Nyasaland, Salisbury, Southern Rhodesia—The Registrar, The University of Birmingham, Edgbaston, Birmingham 15 (October 20)

Senior Lecturer or Lecturer in Biochemistry at the University of Western Australia—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall London, S W 1 (October 27)

Lecturer (preferably with an interest in systematics and anatomy) in Botany in the School of General Studies, Australian National University—The Secretary Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S W 1 (October 29)

Lecturer (with an honours degree or equivalent qualification with an interest in teaching and research in economic geography, particularly the geography of manufacturing and transport, an interest also in cartography and photo-interpretation or in the regional geography of either North America, Africa or South-East Asia would be an advantage) IN GEOGRAPHY at the Newcastle University College, Australia—The Agent-General for New South Wales, 56–57 Strand, London, W C 2, and the Appointments Section, The University of New South Wales, Box 1, Post Office, Kensington, N S W, Australia (October 30)

LECTURER (honours graduate in engineering, physics or mathematics, and preferably with interest and/or experience in factory lay-out, production planning, metrology or metal forming) IN THE DEPARTMENT OF PRODUCTION ENGINEERING—The Registrar, The University, Nottingham (October 31)

ASSISTANT LECTURERS IN ORGANIC, INORGANIC, PHYSICAL or ANALYTICAL CHEMISTRY—The Registrar, The Manchester College of Science and Technology, Manchester 1

LABORATORY TECHNICIAN, to assist in research in the BIOCHEMISTRY DIVISION—The Assistant Secretary, Royal Veterinary College, Royal College Street, London, N W 1

LECTURER IN OPERATIONAL RESEARCH IN THE PRODUCTION ENGINEERING AND MANAGEMENT STUDIES SECTION, Imperial College of Science and Technology—The Dean, City and Guilds College, Exhibition Road, London, S W 7

LECTURER IN RADIATION CHEMISTRY IN THE NUCLEAR TECHNOLOGY LABORATORY, Department of Chemical Engineering and Chemical Technology—Mr G R Hall, Department of Chemical Engineering and Chemical Technology, Imperial College of Science and Technology, London, S W 7

LECTURERS (with at least a second-class honours degree in either physics or mathematics) IN PHYSICS AND MATHEMATICS at the Royal Air Force Technical College, Henlow—Air Ministry, (C E 2m), London, W C 1

PEDOLOGIST (with an M Sc or Ph D degree in pedology, with at least five years experience in soil survey and classification and land classification, and able to make use of aerial photographic maps), for a technical assistance arrangement appointment to the Hashemite Kingdom of Jordan, to conduct and supervise soil survey and classification and land classification—The Director of Recruitment, Department of Technical Co-operation, Sanctuary Buildings, Great Smith Street, London, S W 1, quoting Ref RC 213/179/02

PHYSICAL CHEMIST, to join a research team on sodium transport—Dr Anderson, Medical Unit, King's College Hospital Medical School, London, S E 5

PHYSICIST, Basic grade (with a good degree), for routine and development work in hospital physics—The Secretary, Lambeth Hospital, Brook Drive, London, S E 11

RESEARCH ASSISTANT (graduate in agricultural chemistry, biochemistry, botany or chemistry) IN AGRICULTURAL CHEMISTRY, to assist with an investigation on aspects of the biochemistry of potato tubers affecting tuber quality—The Registrar, The University, Nottingham

RESEARCH ASSISTANT (graduate, preferably with some knowledge of statistics or mathematics), to work in the field of economics, pure and applied—The Clerk to the Faculty of Commerce and Social Science, The University, Birmingham 15

SCIENTIFIC OFFICER or SENIOR SCIENTIFIC OFFICER (honours graduate, preferably with a Ph D in biochemistry, with interests in the isolation and chemistry of proteins, and in studies of enzymes) IN THE PHYSIOLOGY DEPARTMENT—The Secretary, National Institute for Research in Dairying, Shinfield, Reading, Berks, quoting Ref 62/8

ORGANIZING GOVERNMENT SERVICES FOR COMMONWEALTH COUNTRIES

In its full report for the session 1959–60 the Select Committee on Estimates, after carefully considering the arguments for and against the merging of the Colonial Office and the Commonwealth Relations Office, accepted the arguments in favour as desirable from the point of view of administrative efficiency in Whitehall and offering the best way of preserving, for the benefit of independent and dependent territories alike, knowledge and experience that might otherwise have been lost It also considered that the continued existence of two separate Departments of State to deal with the affairs of a rapidly developing and changing Commonwealth leads to a dichotomy of thought and approach that militates against the unity of the Commonwealth It suggested that the new Department, which should be formed on tripartite lines outlined by the Permanent Under-Secretary of State for the Colonies at the time, Sir Hilton Poynton, should be known as the Commonwealth Office and be administered by a single Secretary of State assisted by three or more Departmental Ministers

Although in the Government changes announced in July the Colonial Office and the Commonwealth Relations Office were placed under a single Cabinet Minister, no other effect has been given to these recommendations, although their force has been increased rather than otherwise in the subsequent two years They were criticized forcefully by the Earl of Listowel in opening a debate in the House of Lords on July 17 dealing with aid to Commonwealth countries Lord Listowel, who urged that in no field of policy was a new direction more urgently needed than in that of economic aid and support for the development of the less-developed areas, countries and dependencies in the Commonwealth, thought that the Government had taken the first opportunity of making the change, but he was very dubious as to how far the merger had gone He thought that the Colonial Office was in fact retaining its identity and that to stop short of complete integration was to show a deplorable misunderstanding of the situation, particularly in retaining both titles

Britain has no reason to be ashamed of her colonial record and the Colonial Office has a long and proud history Nevertheless, Lord Listowel is manifestly right in urging that the word should have been dropped in the new title and the office called Secretary of State for the Commonwealth, as indeed the Select Committee's recommendation implied As a consequence of lack of imagination a useful administrative change may well hinder effective co-operation in the economic field between the British Government and those of the new Commonwealth countries Lord Hastings, who concluded the debate for the Government, did indeed promise that these criticisms would be considered and also the further criticism that the Department of Technical Co-operation was too limited by Government policy Even that much response was not forthcoming when Mr P Wall raised the same question in the House of Commons debate on Commonwealth Co-operation on July 30 and suggested the Department of Technical Co-operation should become a Ministry of Overseas Aid, although in the meantime it has been announced that the Colonial Development Corporation is to extend its functions and become the Commonwealth Development Corporation

Much of the debate centred around the first year's activities of the new Department, in which it has spent some £27 million and recruited a further 855 British experts in addition to the 21,000 already serving abroad under its auspices The civil estimates for 1962–63 provide a further sum of about £18 million for the Department, and it expects to spend rather more than last year in aid altogether Lord Listowel thought that the Department should be authorized to handle financial aid also, such as long-term loans as well as grants, and that it should be headed by a Cabinet Minister The situation was urgent because in Africa British technical experts were leaving faster than they could be replaced, and he thought that the only solution was to incorporate such experts in the home Civil Service and then second them for service overseas

The extent of this wastage was rather questioned by Lord Hastings, but although he and other speakers quoted freely from the recent report from the Department of Technical Co-operation and from the annual report of the Colonial Development Corporation, little that was new emerged Lord Twining referred to the importance of the contribution which the Department of Technical Co-operation could make to strengthening the public service overseas Lord Casey again urged the value of international commodity price agreements and thought that the way was now open for practical discussion Technical aid, he suggested, brought in quicker and better results than grant-aid or loans, and his instinct would be to increase technical aid even at the expense of some grant-aid or loans He referred to the relevance of the Freedom from Hunger Campaign now being conducted in the United Kingdom which might raise up to £5 million, much of which would be used to finance and maintain agricultural institutes in the under-developed countries, while Lord Listowel had put Britain's contribution to the support of the poorer countries as some £180 million, apart from private investment

The extent of British aid to the under-developed countries was the other main aspect of the debate in which Government policy came under criticism

Lord Casey did not object to the Government placing a ceiling on the total of economic and technical aid, and agreed that we could not allow increased aid to these countries to endanger our balance of payments Nevertheless, the situation is urgent, at least as much in Asian as in African countries, and, as already noted, if it were necessary to limit the financial assistance, it is the more important that Britain put the utmost effort into technical assistance, and that obviously means giving the utmost support to the Department of Technical Co-operation

Lord Walston was more critical of the Government precisely because he doubted the sincerity of its support for that Department and whether the recent rearrangement meant any real change in policy He did not think that Britain's record of financial assistance compared favourably with that of some other countries, such as the United States or France, and he urged that it was entirely in Britain's own interest to do much more to help the new nations, especially those which show that they are ready to make sacrifices to help themselves It was, next to disarmament, the most vital problem at present confronting Britain

On the magnitude of Britain's contribution, Lord Hastings put Government investments by grant and loan in the Commonwealth and Colonial territories in 1961–62 at £141 million and the overall investment overseas, including private finance, at more than £300 million, or 1 3 per cent of the national income This, however, is not aid in the sense of the recommendation of the report of the Secretary-General of the United Nations which called for 1 per cent annually of the national income of the wealthier countries during the development decade 1960–70 With the vote for the Department of Technical Co-operation under a tenth of this figure, Britain has obviously some way to go before she can expect to escape criticism

What was most disappointing about the debate was that it drew from the Government no indication of any sense of urgency or of opportunity or any sign that imaginative thinking and constructive vigorous policy lie behind recent changes There is, for example, no evidence that the frustration at present confronting the Colonial Development Corporation is viewed with any concern or that the necessary action to remove the hindrances to its operation in the independent territories is being taken with vigour and foresight Here a change of title might be pedantic, but that cannot reasonably be argued of the merger of the Colonial Office and the Commonwealth Relations Office To retain the term 'Colonial' at the present time is impercipient, to say the least, and, on the other hand, the use of the word 'Relations' becomes inappropriate and inaccurate in the new setting The Government has only itself to thank if, on present evidence, it is charged with missing a great opportunity and with failure to measure up to the imaginative measures which the new situation demands, particularly when the way has been carefully sign-posted by the Estimates Committee.

The charge is the more credible in the light of the treatment which the Department of Technical Co-operation has so far received and of the absence of any indication of the future of overseas research The vital importance of an adequate research organization in the emergent nations has been repeatedly stressed during recent months, quite apart from Britain's own particular responsibilities and the uncertainty surrounding the future of the Overseas Research Council One such paper was that on the organization and orientation of applied research in under-developed areas which Dr W H R Lumsden, director of the East African Trypanosomiasis Research Organization, presented last autumn at the South Pacific Science Congress of the Pacific Science Association at the University of Hawaii (see p 1139 of this issue)

Dr Lumsden bases his discussion on his own experience in East Africa since 1947 and seeks to bring out the factors of chief importance and to define the main principles which should determine the organization of applied research in these under-developed areas He points out that while it will be comparatively easy to find support for research specifically and narrowly limited to practical problems, it may be necessary to make special arrangements for research, in which, while directed to the solution of practical problems, the approaches likely to be successful are yet undefined and the use of resources or time is not accurately predictable Much of the first type of research will be essential in the development of a backward country, but limitation of research to that type alone would be unfortunate and the two should be regarded as complementary, providing invaluable mutual stimulants

Dr Lumsden regards the arrangement of good communications as the most vital necessity in planning research in under-developed areas, especially in the scientific field, not only to maintain the impetus of research by continual reappraisal of beliefs and plans, but also in the administrative field so as to facilitate the recruitment of research and technical staff, their administrative support and the supply of materials and essential services Further, he suggests that units should be fairly large and include a variety of disciplines, and he notes that when internal subdivision of supervision is necessary the means of communication should be adequate to take care of problems of mutual understanding The administrative and financial arrangements should be as simple as possible, and since ultimately in these territories applied research will necessarily be carried out by local scientists, early attention should be given to the training and recruitment of suitable local graduates

Once again, the value of linking research institutions with universities is emphasized, both in this context of assisting local recruitment and as contributing to the stimulation of research and the attraction of research workers generally Nor does Dr Lumsden ignore the problem of retaining and recruiting sufficient expatriate workers until the higher educational institutions in the emergent countries are able to ensure a sufficient and continuous inflow of local graduates This is indeed, at present, the main problem, and it is political rather than economic in view of the political instability which often accompanies development

Whether the proposals outlined by the Department of Technical Co-operation in its White Paper on future policy in recruitment for service overseas will prove sufficient, or whether it is necessary to take such a further step as Lord Listowel suggested and incorporate such experts in the Home Civil Service, Dr Lumsden has indicated a field in which the Overseas Research Council should be able to do much useful work Moreover, a number of his suggestions are entirely in line with the thinking of the Zuckerman Report on the management and control of research and development, to the implementation of which the Government is already committed What is vital is that adequate and effective action should be taken early and, although the prime responsibility rests with the Government, the help of professional organizations will also be essential

It is remarkable that while Dr Lumsden nowhere mentions the Department of Technical Co-operation or the Overseas Research Council, his paper points most emphatically to the opportunities which confront the Overseas Research Council if the Department of Technical Co-operation is allowed to use it wisely and effectively The Council is clearly the appropriate instrument to handle some of the problems of communication and of the location of research institutions which were stressed by Dr Lumsden, and it might also contribute to easing the difficulties of recruitment The Council must be given the necessary status, and this seems to be recognized already by the Department of Technical Co-operation though there is no other evidence that the Council is a recognized instrument of the Government or that it possesses its own resources

This in turn means that the Department of Technical Co-operation must itself receive full financial support and that changes in the Government offices should be such as to strengthen, and not to weaken, its authority and status This applies not merely to the Colonial Office and to the Commonwealth Relations Office, though it is essential that Mr Dennis Vosper should be able to count on the understanding and co-operation of Mr Duncan Sandys It is no less important that he should be able to rely on the support of the Minister of Education and the Minister for Science All these, except Mr Vosper himself, are full Cabinet Ministers, and if the Government is really in earnest over technical aid, no step would do more to convince the Nation of its sincerity than to give the Minister in charge of technical co-operation cabinet status with full authority to vitalize the Overseas Research Council and use it effectively, and at the same time consolidate effectively the merger of the Colonial Office and the Commonwealth Relations Office with a title appropriate to the times

COMBINING COMPARATIVE ANATOMY WITH EMBRYOLOGY

Morphogenesis of the Vertebrates

Integrates into a single unit the usually separate considerations of comparative vertebrate anatomy and vertebrate embryology By Dr Theodore W Torrey Pp viii + 600 (London and New York John Wiley and Sons, 1962) 75*s*

THE student of zoology or medicine nowadays needs to consult far more numerous, larger and more expensive books than his predecessors fifty years ago He also has to cover in a smaller and more preliminary part of his course the basic knowledge of human or comparative anatomy and embryology which used to be the entire concern of students in their first two or three years at College It is these two changes of circumstance that Prof Torrey hopes to provide for in a conveniently compact book bringing together, in easily digestible form, the essentials of both vertebrate anatomy and embryology As a stimulating introductory course, this is an undoubted success the subject-matter is well chosen and vigorously presented, with a useful selection of references at the end of each chapter, including many recent reviews All the same, it is doubtful if the text is really digestible, either to the initiated or the uninitiated reader A somewhat colloquial style is adopted, derived no doubt from the spoken words of a lecture course But the slight exaggerations or vaguenesses that are allowable as a manner of speaking, because they can always be qualified or explained afterwards to questioners, are not acceptable in print in a scientific text-book, particularly in one designed for the student who may not have time for the further reading that would correct inaccurate first impressions Torrey's own students, reading this book as a supplement to what one cannot doubt would be a most stimulating and explanatory course of lectures, would certainly emerge well equipped The rest of the world cannot romp through his text with quite the same careless rapture, however, but must take cautious stock of his remarks

It is not easy for one author in one book to do justice both to the dynamic, experimental point of view of present-day embryologists and to the onlooker-antiquarian outlook of the devoted comparative anatomist Experts from either camp will find their point of view inadequately represented Embryologists will feel that Prof Torrey deals too summarily with much experimental work, particularly that on the early embryo, though some of his small-print supplements in chapters on organogeny are excellent A great loss is the lack of mention of experimenters' names though students cannot be expected to memorize these, they should be made to appreciate that any scientific subject is still developing and that well-known individuals are still actively finding out the information that later appears in books This is a great incentive to criticism, in place of the school-child's ready acceptance of facts

Reading the book one has moments of delight at the clarity and beauty of the illustrations, as well as miscellaneous small moments of discomfort over the text The histological illustrations are very good, but electron microscope work is largely ignored an unfortunate omission in the chapters on germ cells, fertilization and muscle The early chapters are excellently begun, with basic principles clearly expressed, but small inaccuracies shake one's confidence later on, such as the not exclusively Chordate character, metamerism, being mentioned as if it did not also occur in invertebrates, and pharyngeal 'clefts' also being listed although they scarcely occur in mammals. The "Preview of Embryogeny", a most helpful preliminary, has only one oddity in the otherwise pleasing sterograms: the foliate shape given to notochord cells, such as is never in fact seen, in life or death. The chapter on cleavage and gastrulation, after some splendidly clear first points, includes one or two dangerous colloquialisms such as that the yolk "makes its influence felt" on cleavage (how often do we have to point out to our own students the fallacy of this favourite text-book dogma?) On the whole, though, this and more particularly the following chapter on early avian development are good and clear, successfully embodying important recent findings, and ending with a well-balanced selection of references.

To describe, next, human development in preference to that of any other mammal is a refreshing innovation, well guarded by Prof. Torrey's emphasis that the human being is not representative of mammals generally. He also, fortunately, digresses to devote much of this chapter to an outline comparison of extra-embryonic membranes in various vertebrates. No other recent book has condensed the same information so lucidly.

In Part 3, "Morphogenesis of Organ Systems", major emphasis is laid on finished structure, and disappointingly little space is devoted to details of morphogenesis. Sometimes, one or two additional sentences, or a series of small diagrams instead of one large one, would remedy this defect. For example, in the chapter on skin two or three diagrams of developing sweat glands could have been added: this might also have precluded the misleading statement that they closely resemble developing mammary glands. In the same chapter too little justice seems done to work on the development of feathers. Reference to Rawles's review (*Biology of Birds*, 1960) could remedy this. Prof. Torrey is, of course, up against the difficulty that students reading his book presumably will not know any comparative anatomy from other sources. It is even doubtful if they could gain enough clear information from some parts of his later chapters, particularly on the development of more complex organ systems. Torrey has decided, allowably, to describe in detail only the mammalian condition, but then it is necessary either to omit the too sketchy references to other forms, or to fit the mammal clearly into a comparative vertebrate series first. One is lost when he leaves out the mammal from each of his series of comparative diagrams: for example, of cœlom divisions, urinogenital system, arteries, and veins. He goes on to illustrate the mammalian condition in detail, but one does need first a diagram in the same style as previous ones in order to see the mammal in its proper sequence. Admittedly, this part of the book is aimed more at the medical student than the comparative zoologist: for example, in its detailed description of human musculature. But medical teachers may be worried, too, by remarks like the optimistic suggestion that we understand the functions of cardiac jelly, and the simplified description of interventricular septum development, omitting all reference to the septum membranaceum, which is an important site of developmental defects of the heart.

The best balance between comparative description and references to present-day research is achieved in the chapter on the urinogenital system, as one might expect since this is the author's own research field. He reveals also his special interest in sense organs, in introducing them from the Protozoa upwards (yet why not choose Ciliates, with their delightful 'organelles', as examples in preference to *Amœba*?). A slight incongruity is the description of eye structure before its development: also the discussion of neural induction might well have come earlier in the book. Incidentally, it is surprising that he does not refer to Yamada's and Toivonen's recent work in this field (well reviewed by Yamada, 1961, in *Advances in Morphogenesis*).

The glossary, complete with derivations of words, is a valuable addition to the book and will increase the student's understanding of the subject. This is indeed a book well worth study, as it shows to the teacher as well as the student how hard it is to embody these two approaches in one course, and how essential it is to try to do so.

E. M. DEUCHAR

PLANNING THE WAY FOR UNIVERSITY EXPANSION

The Expanding University

A Report. By W. R. Niblett. Incorporating papers by Sir Charles Morris, Lord James of Rusholme, J. S. Fulton, D. G. Christopherson and R. M. Ogilvie. Pp. 132. (London: Faber and Faber, Ltd., 1962.) 18*s*. net.

THIS is a stimulating book; it is the outcome of a conference held by the University Teachers' Group in Oxford in October 1961, and it is built around a series of papers, which are given in full, by those leading university figures—Sir Charles Morris, Lord James of Rusholme, Mr. J. S. Fulton and Dr. D. G. Christopherson—who are playing an outstanding part in the shaping of Britain's existing and new universities. It includes also a most welcome and important paper by one of the new generation of academics, R. M. Ogilvie, on "The Role of the Teacher". It is sometimes difficult for those who were deeply involved in the universities before the Second World War to appreciate the changes in outlook of the post-war generations and, if only on this account, Mr. Ogilvie's paper is especially valuable. These individual papers are held together by summaries of the discussions which followed them and the whole has been admirably moulded by Prof. Niblett, dean of the University of London Institute of Education. It must have been a lively conference, and this is clearly reflected in the book.

There is a danger to-day that all thought on what universities should be and do ought to be left to the Robbins Committee; the appointment of a Royal Commission or its more modern counterpart is so often taken to be a sign for academic hypo-thermia. Nothing could be more unfortunate at this time. The Robbins Committee has been asked to deal with the pattern of higher education, and while it may well be that the universities will find themselves with stronger, and even new, partners in this field, it is most improbable that the Robbins Committee will recommend for the universities a smaller or less-responsible role than they fulfil to-day. Moreover, the pattern for the next ten years is already fairly well set by the Government's recent decisions on universities, colleges of advanced technology and the teacher training colleges This is not, therefore, the time to sit back waiting for Robbins, if the next generations of students are to get a fair deal

This book is also therefore timely While making a wide survey of the universities' academic and social problems of to-day, emphasis lies on what the universities could do better than they do now for the undergraduates The increasing impact of research and postgraduate education is not overlooked but discussion centres on the welfare of the undergraduates, including aspects of their life other than mere class-room and laboratory education This is perhaps brought out most clearly in Mr Ogilvie's paper He claims that the new student lacks interest and drive, but whose fault is this? He then singles out three qualities with which students should be equipped when they leave the university—individualism, interest and integrity He himself admits that these are not new ideas, but it is certain that they need restating to-day

One of the real dilemmas facing the universities is the dual claims of teaching and research The demands for more research, particularly in the pure and applied sciences, are increasing every day Unless the universities are put in a position to recruit and retain academic staff, the claims of research can be met only at the expense of the undergraduate It must have been fear of this disequilibrium that led the University Grants Committee to set up the Hale Committee to study undergraduate teaching methods and practices current in the universities

This book makes it clear that the universities are well aware of the academic problems arising from expansion and, given adequate resources, that they have the will to solve them It could not have arrived at a more opportune time, discussion now is the means of avoiding many of the real dangers of expansion

VITAMIN B_{12}

Vitamin B_{12} und Intrinsic Factor

Zweites Europaisches Symposium, Hamburg, 2–5 August 1961 Herausgegeben von Dr H C Heinrich. Pp xx+798 (Stuttgart Ferdinand Enke Verlag, 1962) 142 DM

SINCE the isolation of vitamin B_{12} in 1948 by Lester Smith in England and by Folkers and his co-workers in the Merck Laboratories in the United States two symposia have been held, both in Hamburg, to discuss the many aspects of interest in the vitamin The first symposium was held in 1956 at a time when the structure of the vitamin had just been established, in the main by the brilliant X-ray work of Mrs Hodgkin (Dr Dorothy Crowfoot) and her associates in Oxford The highlight of the second symposium (recorded in little more than four pages in the volume under review) is the disclosure of the structure of the vitamin B_{12}-containing coenzyme It is a cobalt-organo-metallic compound containing a cobalt–carbon bond derived in a formal sense from vitamin B_{12} by the displacement of the cyano-group by the 5′-methylene-group of 5′-deoxy-adenosine (the valence state of the cobalt in the coenzyme is in some doubt) This dramatic and startling discovery is again to be attributed to Mrs Hodgkin and her collaborators The other important contribution, that of H A Barker, from the Department of Biochemistry, Berkeley, California, concerns the observations (made mainly in his laboratory) of the remarkable biochemical reaction of vitamin B_{12} in converting L-glutamic acid to L-β-methyl aspartic acid Barker's paper is also a gem However, it is a pity that, in the volume as printed, speculations in Barker's paper concerning the constitution of the coenzyme are allowed to remain when, in the succeeding paper, Mrs Hodgkin details its structure It is left to the reader to refer back to the preceding paper by Barker and to make his own rationalizations

The volume under review contains eighty-one papers (from the seventy-two contributors), sixty-one of which are in English and twenty are in German Dr Heinrich, of the Physiological-Chemical Institute in Hamburg, has attempted the herculean task of editing these contributions, and he is to be congratulated on his effort

The contributions range from Prof A W Johnson's succinct discussion of attempts to synthesize the vitamin (or, at least, the fundamental heterocyclic system, corrin, of which vitamin B_{12}, cyanocobalamin, is a derivative) to aspects of the pathology of and the therapy of vitamin-B_{12} deficiency

It is clear that no editor can command a critical knowledge of so diverse fields, and the contributions quite naturally vary in quality Moreover, with contributors from Bethesda and Budapest, Stockholm and Sofia, it is not surprising to find an article on the analytical chemistry of the corrinoids written in English by a Polish biochemist and edited by a German physiologist Needless to say, one admires the attempt, but can only deprecate the results, with the attendant errors of mis-spelling and mis-interpretation On page 291, for example, there are at least seven spelling mistakes, none of them serious if one knows the field However, in Friedrich's article on the partial synthesis of B_{12}-type vitamins (pp 8–28) it is quite obvious that the author would never have embarked on the particular course he chose had he been aware of the now classical work of Winstein, in California, extending over the past twenty years, on neighbouring group participation

The volume is made up of eleven sections, ranging from the chemical through the biochemical and physiological to problems of nomenclature The quality of the production is excellent although the opening pages of photographs of selected participants seem ill-placed and irrelevant

One feels that the symposium was eminently worth while What must be asked, however, is whether the proceedings should have been published, particularly in their present form They are not of general interest Moreover, the book is inordinately expensive It contains no record of discussion, and it is plagued with errors, not only in spelling, but also in the formulation of ideas

It is hoped that the success of the second symposium (as stated in the preface to the present volume) will encourage a third such symposium, but I can only suggest that the proceedings are not published—at least in the present form The participants should be encouraged to publish in the accepted media of scientific intercourse and exchange

The title of the book mentions "intrinsic factor", but only one of the eleven sections is devoted to this topic and it ends with a contribution entitled "Does Intrinsic Factor Exist?"

The book takes as its leitmotive the quotation from Fanny Rosenblum that "B_{12} is not a vitamin, it is a fraternity" Considering the contributions of Mrs Hodgkin and her co-workers, one is tempted to ask if B_{12} is not better described as a sorority

V M Clark

The Genus Monadenium, with Descriptions of 21 New Species

By Peter R O Bally Pp 111+34 photographic figures+32 plates (Berne Benteli-Verlag, 1961) n p

THE genus *Monadenium* is a close relative of *Euphorbia*, the spurge genus, differing in the structure of the inflorescence It is altogether confined to tropical Africa, and almost restricted to East Africa Although, with some exceptions, the species are not distinguished for their ornamental qualities, their life-history is full of interest, particularly in the way that their structure has become adapted for the evasion or endurance of a rigorous climate Their habit ranges from herbs an inch or so high with underground storage-organs to succulent-stemmed trees of 18 ft

So happy a union of botanical skill and artistic excellence as that shown by Mr Bally is but rarely found The result is an authoritative taxonomic revision of the forty-seven species of *Monadenium* (twenty of which were first described by Mr Bally himself), coupled with 32 splendid plates, the majority coloured, from the author's talented brush The usual herbarium specimens of this genus are so deplorable that plates of this sort, made from living plants, become not only ornamental but also a necessity

Indeed, this revision indicates very strongly the value of a knowledge of the living plants in their native home in producing good systematic accounts of difficult genera which respond poorly to the normal methods used for preparing specimens for the herbarium

In spite of the sub-title, which has an odd contradiction between the dust-cover and title-page (18 new species on the former, 21 on the latter), only three of Mr Bally's species are described here actually for the first time. J P M BRENAN

The Pattern of Progressive Mineralisation in Human Dental Enamel

By Dr H S M Crabb and Dr A I Darling (International Series of Monographs on Oral Biology, Vol 2) Pp xi+99 (London and New York Pergamon Press, 1962) 35*s* , 5 50 dollars

THE nature and mode of development of dental enamel have engaged the attention of histologists and other workers for many years, but owing to the relative difficulty of working with this tissue it has not received so much attention as have most other tissues of the body Special techniques have also been more important in the microscopy of enamel than in the case of other tissues, and thus much of the evidence on which our present theories of the development and mineralization of enamel are based depend on microradiography and polarized light microscopy as well as on information derived from studies of decalcified material by ordinary transmitted light

Interpretation of the findings yielded by the various techniques have in the past shown considerable variation, and as a result opposing and contradictory theories of the pattern of enamel mineralization have been current Workers in this field will, therefore, welcome this authoritative monograph, which gives a clear and succinct account of recent research on enamel mineralization The authors discuss and criticize the older theories and put forward their own conclusions, which agree very closely with those recently obtained by other groups of workers It seems clear that the older views of enamel maturation cannot sustain critical re-examination, and that ideas much closer to those now put forward will take their place R B LUCAS

The Preservation of Timber

By Dr W P K Findlay Pp xiii+162+14 plates (London Adam and Charles Black, 1962) 25*s* net

MUCH has been written about the preservation of timber, but Dr Findlay has succeeded in putting into one book, and in easily understandable form, the information on the subject required by architects, builders, householders, farmers and a host of others The reader is given the necessary basic essentials of the subject in chapters on "The Nature and Durability of Wood", "Agencies of Destruction", "Preservative Methods" and "Wood Preservatives" Non-pressure, pressure and diffusion treatments are described, and the preservatives are also classified into the three main groups of tar-oil derivatives, water-borne chemicals and chemicals in organic solvents The advantages and disadvantages of each kind and the methods of application are discussed. Most of the succeeding chapters deal with wood preservation for specific requirements such as building timber, woodwork in garden and farm, timber in constant contact with water and the large category of poles, sleepers and mining timber The preservation of wooden antiques is also considered Fire-retarding methods are described and the author ends with well-chosen examples demonstrating some economic aspects of wood preservation

Dr Findlay has dealt with his subject in a concise and very masterly manner His book provides the information to enable the most suitable preservative to be chosen for a particular purpose and to be used to the best advantage In an appendix is a list of the preservatives generally available in Great Britain

All users of timber and timber products will welcome this informative and very well-illustrated book C J TAYLOR

Reports on Astronomy

Edited by D H Sadler (Transactions of the International Astronomical Union, Vol 11A—Reports) Pp viii+579 (London Academic Press, Inc (London), Ltd , New York Academic Press, Inc , 1962) 80*s* net , 11 50 dollars

THIS volume of *Transactions*, which has appeared in less than a year after the 1961 meeting of the International Astronomical Union, contains the draft reports of the Commissions as presented to the General Assembly and later amended As usual these reports review the work done in each field covered by the Commissions since the preceding meeting, together with an extensive bibliography The reports of the Commissions on Notation, Bibliography, Telegrams and Exchange of Astronomers have not been published in this volume These four reports will be published in Transactions 11 *B* in view of their administrative character

Volume 11 *B*, to be published later, will contain the proceedings at the 1961 General Assembly, the resolutions adopted, the invited discourses and other business of the Union This new policy of publishing separately the reports of the Commissions and the proceedings will be greatly welcomed since the rapid publication of the reports enhances their value as a reference work D MCNALLY

ORGANIZATION AND ORIENTATION OF APPLIED RESEARCH IN UNDER-DEVELOPED AREAS*

By Dr W. H. R. LUMSDEN

Director, East African Trypanosomiasis Research Organization, Tororo, Uganda

THE discussion regarding the organization and orientation of applied research in under-developed areas which is here presented is based on my own experience in this sphere of research in East Africa since 1947, and, particularly, as director of the East African Trypanosomiasis Research Organization since 1957 The factors important in relation to the organization and orientation of applied research are many and miscellaneous and so are difficult to summarize It seems most suitable to describe the subject, as it appears in my East African experience, under three headings (1) the scope of applied research, (2) the development of trypanosomiasis research, (3) general research development, 1947–61 —so as to exemplify and discuss points of importance, and then to attempt to define main principles

Scope of Applied Research in East Africa

If 'basic' research may be defined as research unrelated to any immediately obvious practical application, then practically all the biological research which has been done in East Africa, except for recent research in the University of East Africa, may be described as 'applied' in that its financial support has been derived from the existence of obvious practical medical or agricultural problems Examples are

(a) Trypanosomiasis research, related to sleeping sickness, still mainly limited in its impact on man only by leaving unoccupied the areas known to be infected, and to nagana, which still denies huge areas of Africa to cattle

(b) Virus research, related mainly to arthropod-borne virus diseases, even though yellow fever is restricted in importance by the application of vaccination, other virus diseases, such as chikungunya, are still liable to appear, causing extensive epidemics and temporarily incapacitating large populations

(c) Agricultural research dealing with a multitude of problems—the effects of soil characteristics and climate on crop growth, crop selection and improvement, methods of animal husbandry, the prevention of disease of livestock, and so on

Although all this research may be designated as 'applied' there are wide differences in scope between different investigations and between the programmes of different laboratories It is impossible rigidly to classify research, but as regards East Africa it will be convenient to recognize two main types of approach differing in scope

Type A Research specifically and narrowly limited to the practical problem in question Such research will usually involve the application of known techniques, and will usually be fairly accurately predictable as regards the time and resources needed to fulfil it An example might be the choice of a strain of crop suited to the climate of a given locality.

Type B Research, still directed towards the solution of practical problems, but in which the approaches likely to be successful are yet undefined Such research will not be accurately predictable either as regards the use of resources or time, and freedom must be accorded to the workers concerned in it so that they may explore any avenues which appear promising to them An example might be the development of laboratory methods for separating *Trypanosoma rhodesiense* from the morphologically similar, but non-man-infecting, *T. brucei* and for diagnosing infections with these organisms in wild or domestic animals; methods for these purposes can only be developed by trial and error of indefinite duration

Clearly, a great deal of type *A* research will be essential in the development of an emergent country but limitation of research to that type alone, which is a point of view often canvassed, has its pitfalls The results of investigations with this limitation, needed for immediate practical purposes, will usually be embodied in reports which may have only a restricted circulation, and so will not necessarily be subjected to the independent critical assessment which is one of the main functions of formal scientific publication Most type *B* research will be carried out with the view, ultimately, of publication, and so from type *B* workers may be expected to come the periodical challenge of beliefs which is essential if practices are to be thoroughly soundly based

So, for developing countries, both types of research scope are necessary, they should be regarded as complementary to each other, as the mutual stimulations between them are invaluable There exists, however, the possibility of frictions arising between the workers engaged in the two types Such difficulties will sometimes be the manifestation of competition for limited funds for research Money for a research project will, in countries with small financial resources, be the more easily forthcoming the earlier any economic or public health advantage appears likely to ensue Thus, type *A* research will be comparatively the easier to find support for and special arrangements may be necessary for the other type. Desirably, the support and supervision of type *B* research should be invested in some council of good scientific standing which can assess and balance without bias the importance of various competing points of view and which can protect type *B* research from the too importunate demands for immediate action on special aspects which may dislocate planned programmes Such an authority should be politically independent, difficulties in collaboration and co-operation may arise if bodies politically different, and therefore perhaps competing for funds, support different types of research within the same general field

---

* Substance of a paper presented to the Tenth Pacific Science Congress of the Pacific Science Association, held in the University of Hawaii during August 21–September 6, 1961, and sponsored by the U S National Academy of Sciences, Bernice Pauahi Bishop Museum and the University of Hawaii (See also p 1133 of this issue)

In under-developed areas also, distance and poor communications may make contact between workers infrequent and so, sometimes, lead to misunderstandings and unproductive rivalries between workers engaged in the two general types of applied research Probably the most fruitful liaisons between research workers, and with the executive technical workers engaged in the practical applications of research, is by informal reciprocal visits But emergent Governments, anxious to ensure that they derive value for the money they expend on research, may demand more formal arrangements such as committees and seminars at which all types of worker may meet

Development of Trypanosomiasis Research in East Africa

The devastating sleeping sickness epidemics in the Lake Victoria basin early in the century stimulated work which established the basic facts of the ætiology and transmission of the trypanosomiases, and a great deal of well-balanced work, taking into account many aspects of the diseases, continued up until the 1920's A change in emphasis occurred in the 1920's and research became largely concentrated on one single aspect of trypanosomiasis—the ecology of tsetse flies (*Glossina*) The reasons for the decision to concentrate on this aspect, which was mainly due to C F M Swynnerton, appear to have been that, lacking efficient drugs for treatment or prophylaxis, attack on the insect vector appeared to offer the only hope for the eradication of the trypanosome diseases, that with the techniques then available, investigations of the interrelations of host and parasite—on immunity and 'tolerance'—gave only disappointing results, that much of the general interest in the field was by German scientists who withdrew when Germany lost her East African territory

Concentration of the main research effort on the ecology of *Glossina* continued practically unbroken until comparatively recently Only in the past few years has a return taken place to a more comprehensive approach in which the contributions of several different scientific disciplines are integrated The main considerations determining this recent readjustment were

In the event, the long-drawn-out concentration of research on the ecology of *Glossina* gave only disappointing results as regards its main aim—the development of economical and reliable methods for eradicating these flies as a single 'key' measure to prevent the diseases they transmit The great zoological interest of the work of Swynnerton and his successors must be recognized, for example, the studies of Jackson on methods of estimation of wild populations are of fundamental importance It is equally necessary, however, to recognize that the great body of work on tsetse biology has influenced practical control measures comparatively little Bush clearing and game destruction are still in use as main control measures with little fundamental change in the way that they are applied The most considerable change in methods of tsetse control or eradication in recent years has been the introduction of insecticides, that is, a change not primarily derived from ecological research on *Glossina* but from commercial chemical research, and even this development may leave the purely vector control approach with intractable problems of preventing re-infestation, after insecticidal application, either by re-invasion or by the expansion of relict populations

Secondly, the range and efficiency of drugs for the cure or prophylaxis of trypanosomiasis both in man and animals have enormously improved in the last forty years In particular, the introduction in the 1940's of drugs promising prolonged prophylaxis in cattle raised hopes of productive pastoral industries, at least in areas of low tsetse density, without the prior eradication of tsetse flies, even though these drugs were not without their attendant complications in use, such as the appearance of trypanosome strains resistant to them

When the trypanosomiasis problem was considered in the light of these two main arguments it was evident that there was need for better understanding of host–parasite relations and of the ecology of the diseases in Nature—of the mechanisms of mammalian immunity, or adjustment, to trypanosome infections, of interactions between these mechanisms and the effects of drugs, and of the ways in which particular trypanosome species survive and are transmitted in Nature Thus, present research is mainly concerned with problems which cover a wide front and require the concurrent contribution of several different disciplines for progress to be made Examples are the yet unexplained discontinuity of the distribution of *Trypanosoma rhodesiense* sleeping sickness within the distribution of those species of *Glossina* which are believed to be its main vectors, and the need to measure, in relation to the planning of régimes of drug prophylaxis, the degree to which cattle are exposed to infection in Nature—the trypanosome 'risk' Such problems demand the collection of information regarding the habits of the men or animals becoming infected, the re-orientation of entomological studies to provide information on the periodicity and spatial distribution of vector attack on man and animals, and the development of laboratory methods for the recognition of trypanosome species and infected hosts by immunological methods and for the measurement of certain of the important biological characteristics of trypanosomes, such as infectivity and drug resistance

The foregoing résumé of the development of trypanosomiasis research in East Africa illustrates the importance of a wide comprehension of the mechanisms of transmission of a disease if its prevention is to be logically and efficiently developed, undue preoccupation with a single 'key' measure may prove disappointing. It illustrates, also, the importance of the frequent questioning of research trends so that the momentum of research may be maintained by continually adapting to the changing situation Such reappraisal may not be automatic in research fields which tend to isolation from others, as did African trypanosomiasis because of the limited geographical distribution of its vectors Unless such reappraisal can be accomplished, research direction may be dominated by groups of workers of restricted experience who may not appreciate the possibilities of other approaches—or of combined approaches A first need, then, is to avoid the isolation of individual workers, or of groups of workers of a single discipline —situations which are peculiarly likely to arise in under-developed countries For them to continue actively original and self-appraising, research units should desirably not be too small (at least six workers) and should include a variety of disciplines Also, consideration may be given to arranging interchange of workers with other, related, fields from time to time and for reviews of the field by independent scientists of high standing, the reviews made by Buxton[1], Davey[2] and Hornby[3] have been invaluable in planning the recent re-organization of trypanosomiasis research

General Research Developments in East Africa (1947–61)

In the late 1940's the present research organizations of East Africa, in both medical and agricultural fields, were in the process of establishment In those days workers were fairly easily available, but there were scarcities of buildings, equipment and money Communications were little developed, and little difference in suitability as sites for research institutes appeared to exist between one place and another Thus, in the siting of research institutes, although isolation was sometimes recognized as to be avoided, availability of buildings and easy access to the field were more often determining factors Sometimes political factors were dominant

The perspective in 1961 was very different, development of communications had improved enormously the suitability of some sites while others remained practically unaffected In cities such as Nairobi and Kampala the facilities scarcely differ from those of a provincial university town in a temperate country, laboratories sited in such cities, or near them on main lines of communication, now contrast noticeably with those more isolated

From good siting much else with regard to organization and orientation appears to flow A research institute sited in good communication with a major centre of population will be much easier to run because of the availability of skills for the maintenance of general services and scientific equipment The better scientific contact also available in or near such centres is important for avoiding the intellectual stagnation which may overtake more isolated institutes Continual scientific contact is more generally important than continual access to the field so long as communications are good enough that access to the field is reasonably easy when it is required, as they are now, widely, in East Africa Siting is also important with regard to the orientation of research, orientation depends largely on securing workers interested and skilled in the particular kinds of investigation required For reasons of general amenity, as well as of good scientific contact, there will usually be a larger 'field' of applicants, from which suitable workers may be selected, for posts in institutes in good communication

Conclusions

The main thesis of this article is that the most vital necessity in planning research in under-developed areas is to arrange good communication, most importantly in the scientific field, to maintain the impetus of research by continual re-appraisal of beliefs and plans but also in the administrative field to facilitate the 'logistics' of research—the recruitment of research and technical staff, their administrative support, and the supply of materials and essential services Examples of the importance of good communication are cited with relation to (*a*) The maintenance of productive and stimulating relations between the workers engaged in different scopes of applied research and between them and executive technical workers (*b*) The maintenance of the impetus of research by frequent re-appraisal of beliefs and research plans by good communication both among the workers engaged in any particular field and between them and those engaged in different, but related, fields (*c*) For the attraction and selection of suitable workers (*d*) For general administrative reasons

There are a few other points regarding communication which require mention The desirability of units being fairly large and including a variety of disciplines has been mentioned It is difficult, however, for a single senior scientist to keep close scientific contact with more than a limited number, probably four or five, more junior workers Thus in units larger than this size some internal subdivision of supervision will be desirable So that reviews of progress and decisions as to the amendment, re-inforcement or abandonment of plans may be made rationally at suitable intervals, designation of certain areas of the work as named 'projects' may be necessary With regard to communication with another, non-scientific, cadre concerned in applied research—government administration—problems of reciprocal lack of understanding of points of view between scientists and administrators, not absent in more advanced countries, may arise Basically, administrative and financial arrangements should be as simple as possible

This article has been written on a basis of the research workers in an under-developed country being expatriates from more advanced lands, and this will typically be the initial situation in emergent countries Ultimately, however, applied research in these lands will necessarily be carried out by local scientists, and early attention should be given to the training and attraction into research of suitable local graduates A main problem will be retention and recruitment of sufficient expatriate workers to tide over until local scientists become available Salaries will require to be adequate in comparison with those offered in the countries from which the workers are derived, but, as development of a country is often accompanied by political instability, some special arrangements may be necessary to retain and attract staff Desirably, expatriate workers should be associated with some parent institution in their home countries so that they may not necessarily regard themselves as irrevocably devoted to expatriate careers and so that they may be reasonably confident of returning to suitable employment in their own countries when they so wish or when their services are no longer needed Probably the most productive arrangement for the future, so far as East Africa is concerned, would be the attachment of research organizations to East African and European universities so that, as well as the advantages mentioned above, research on the problems of under-developed countries could be kept in the view of senior undergraduates as a full and satisfying career

I thank Mr J S McClay, my administrative secretary, discussion with him has been invaluable to me in formulating the ideas here presented

CERES: AN AUSTRALIAN PHYTOTRON

CERES, the Controlled Environment Research Laboratory of the Commonwealth Scientific and Industrial Research Organization, recently completed at Canberra, was officially opened by the Prime Minister of Australia, the Right Hon. R. G. Menzies, on August 29. Although operated by the C.S.I.R.O. Division of Plant Industry, a large group of biologists covering many disciplines, *Ceres* is to be a national facility available for use by other C.S.I.R.O. divisions, universities and Departments of Agriculture, as well as by visiting overseas scientists.

A phytotron is a building in which a large number of controlled environments is provided for the study of the responses of plants to climatic conditions. The first phytotron was built at Pasadena in 1949, and others on a scale comparable with *Ceres* have been built at Moscow and Paris, while there are also several smaller ones such as that recently built by the Colonial Sugar Refining Co., at Brisbane, for work on sugar cane[1]. All these consist of a relatively small number of rooms maintained at set conditions, and by moving plants from room to room they can be exposed to a large number of climatic conditions. Rather more than one-third of the plant-growing area in *Ceres* is organized in this way.

An alternative, of advantage when greater accuracy of environment control is required, is to have a large number of small cabinets, each under individual control, and each capable of providing a wide range of conditions. Five cabinet types, differing in size and in the climatic components controlled, have been developed to provide the remainder of the plant-growing area in *Ceres*. The majority of these, some 180 units, with a total area of 1,300 sq. ft., are naturally illuminated, but provide close control of temperature and day-length. Artificially illuminated growing space, about 800 sq. ft. in area, is provided in forty-five cabinets, some of which also provide control of humidity over a very wide range.

The high proportion of naturally illuminated space was determined by favourable light intensity and day-length conditions in Canberra, even in winter, and by the particular interest of the Canberra group in relating responses under controlled climatic conditions to those in the field. On the other hand, it is expected that with increasing sophistication and experience in the use of these controlled environment facilities will come increased pressure for greater accuracy and complexity of control, and ample space has been left in the building for an increase in the complement of artificially illuminated cabinets. It was in this space that the opening ceremony was held.

The naturally illuminated cabinets are placed in a series of 15 glasshouses along the north side of the building. Each glasshouse has independent temperature control, being conditioned by a number of reverse-cycle units specially developed for this purpose. These act as benches on which plants can be grown, and can be readily moved from one glasshouse

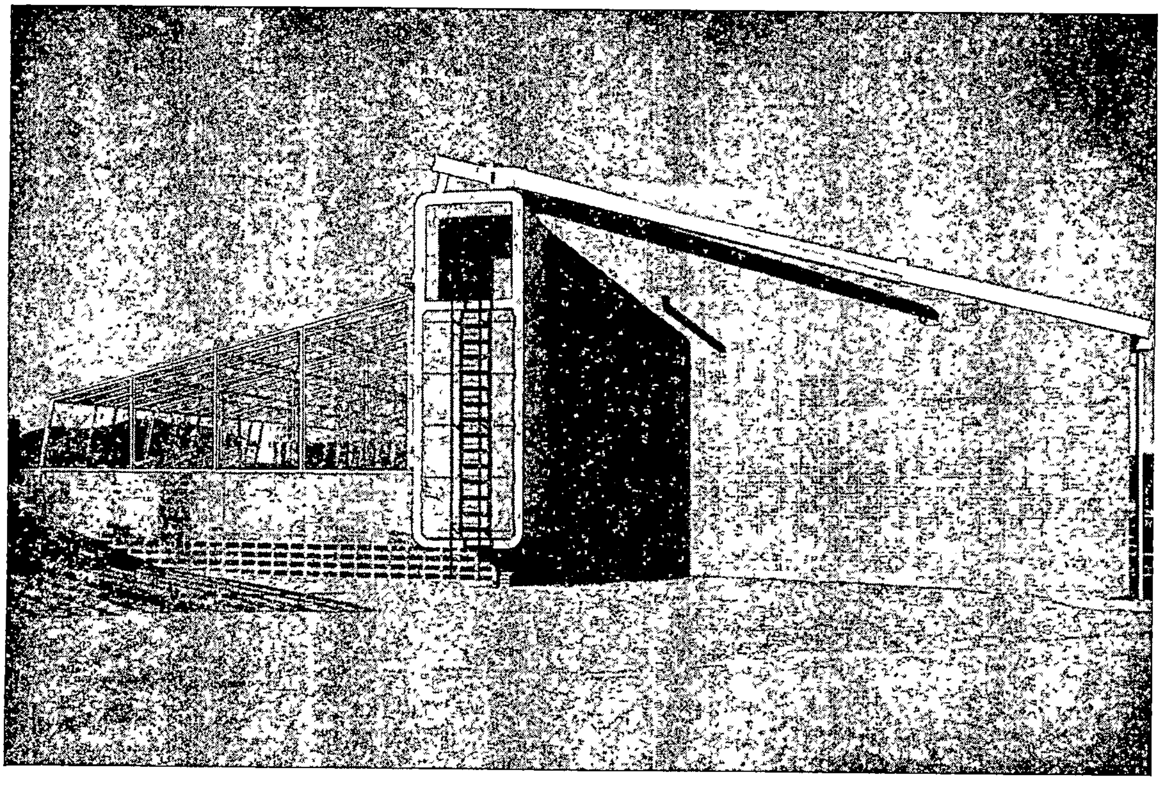

Fig. 1. *Ceres* from the west. The glasshouses are on the north side, at the left, with the grille of the thermal storage pond below them. On the south side of the building are the workshop, preparation area and artificially illuminated cabinets and dark rooms. The main fumigation chamber can be seen at the centre of the photograph.

to another—as can the cabinets—giving great flexibility in operation Heat removed from the glasshouses during the day, and from the sealed light canopies of the artificially illuminated cabinets, is stored in a large pond under the building, whence it may be withdrawn during reverse-cycle operation at night and in the hotter glasshouses by day

As in the Pasadena phytotron, *Ceres* will be kept free of pests and diseases by passing all air through electrostatic precipitators, by fumigating all equipment and plant materials, and by change of clothing for personnel, on entry to the building Additional details of the design have been given elsewhere[2]

The Canberra phytotron was initiated several years ago by Dr O H Frankel, then chief of the Division of Plant Industry. It was made possible by the development of a range of both naturally and artificially illuminated cabinets of a high level of performance and reliability by Mr R N Morse and his colleagues of the C S.I R O. Engineering Section They also developed the system of glasshouse conditioning, and suitable electronic controllers for both glasshouses and cabinets The building was designed by Grounds, Romberg and Boyd, with W E Bassett and Partners as consulting engineers It was built and equipped with funds made available by the Commonwealth Government in 1958, at a total cost of about £A600,000

EVIDENCE FOR A FURTHER IONOSPHERIC LEDGE ABOVE THE F_2 REGION

By PROF J. SAYERS, P. ROTHWELL and J H WAGER

Department of Electron Physics, University of Birmingham

SATELLITE *Ariel*[1], which was launched from Cape Canaveral on April 26, 1962, carries instrumentation to measure the local ionization density along the path of the satellite These data are stored point by point along each orbit by a tape recorder on board the satellite, and relayed by fast play-back over the telemetry link on command from a ground station *Ariel* is, therefore, the first satellite with instrumentation and a data-recovery system capable of providing a rapid world-wide survey of the distribution of ionization over the range of altitude and latitude covered by its orbit This, in effect, means a scan of ionization between latitudes 54° N and 54° S , and in the geocentric altitude range of 400–1,200 km

The electron or ionization density is measured by a new radio-frequency plasma probe which has been developed for ionospheric investigation The sensors are in the form of two disk-shaped grids of 4-in diameter and 3½ in apart These grids are mounted on insulating supports at the end of a 4-ft boom projecting radially from the equator of the satellite In operation a radio-frequency voltage of approximately 3 0 V root mean square and 10 Mc/sec frequency is applied between the grids

The radio frequency current which flows between the grids in response to this voltage is measured in magnitude and phase and the complex impedance of the plasma between the grids is thus determined at 10 Mc/sec frequency This enables the electron density to be calculated directly, and since radio

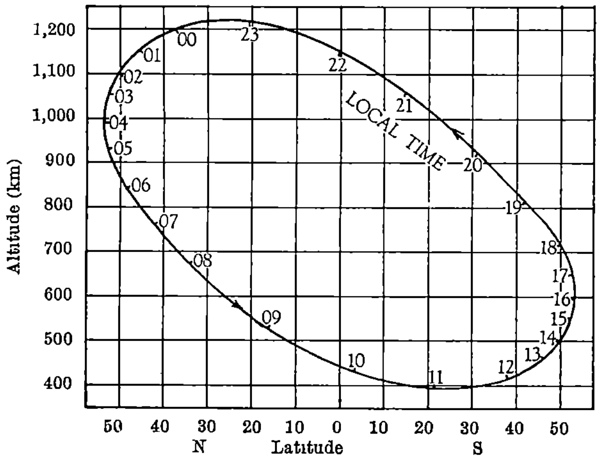

Fig 1 *Ariel* orbit of May 13, 1962

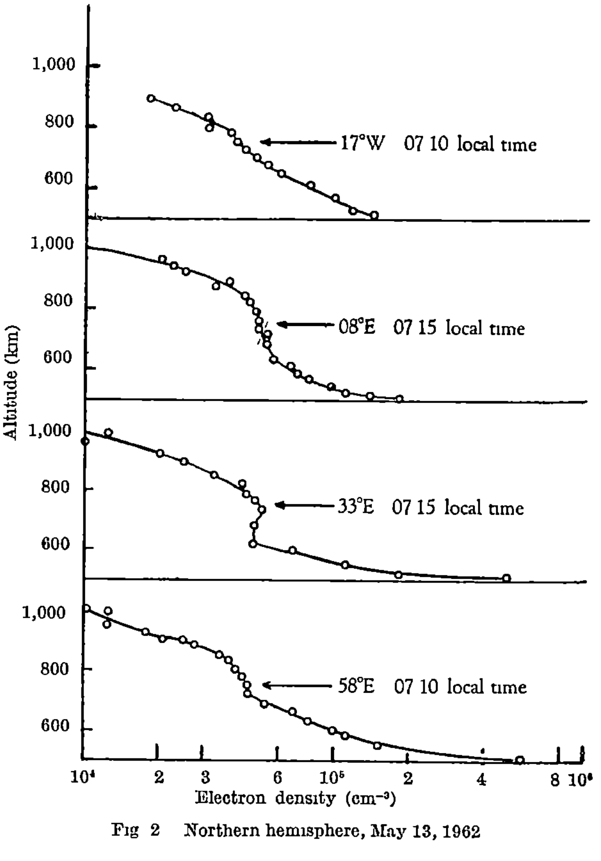

Fig 2 Northern hemisphere, May 13, 1962

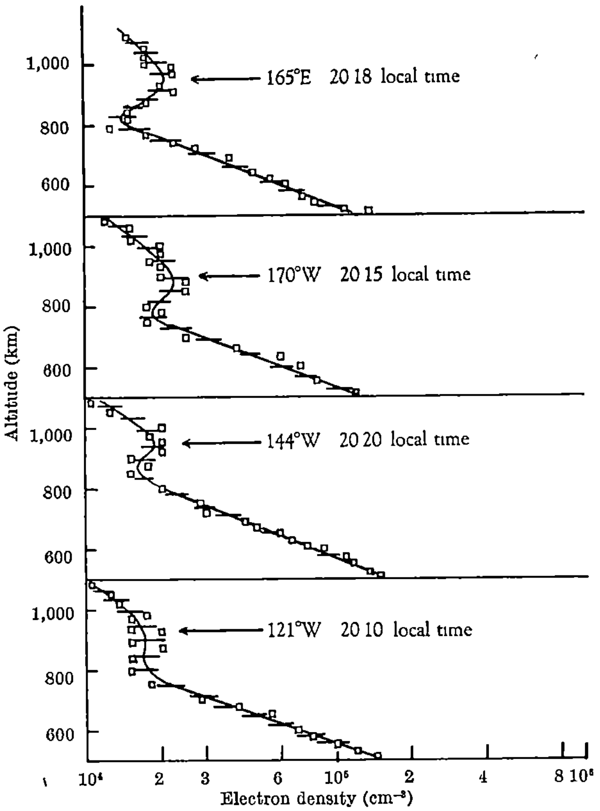

Fig 3 Southern hemisphere, May 13, 1962

frequency currents only are measured the d.c. currents due to photo-emission or secondary emission of electrons at the grids do not disturb the measurement. The effect of positive ion sheaths in excluding electrons from part of the region between the grids is eliminated by a d.c. sweep voltage applied to both grids and their support structure. This enables observations to be made with the grids at the plasma space potential.

The entire world-wide scan of ionization distribution requires several months of satellite orbit precession, and at the time of writing about half this scan is complete, and significant new results have resulted from the analysis of a representative selection of the data. The following conclusions have been drawn from this analysis.

(1) The density of ionization above the F_2 region of the ionosphere falls away with increasing altitude in the range of 400–1,200 km (geocentric), generally on a world-wide scale according to approximate diffusive equilibrium in the earth's gravitational field. This is in agreement with earlier measurements by *Explorer VIII*, vertical sounding rockets and back-scatter radar soundings[2-7].

(2) There are complex variations in the ionization density in this altitude-range, both temporal and geographical, which are comparable in relative magnitude to the corresponding variations in the F_2 region. This result is, of course, just what might have been expected.

(3) Superimposed on (1) and (2) there is very strong evidence for the existence of a further ledge of ionization at very much greater altitudes than F_2. This ledge has been observed regularly on a world-wide scale on every transit of the satellite through the altitude-range which has so far been analysed. These include a total of approximately 60 transits selected at random over a period of 2½ months.

The results obtained on four consecutive orbits on May 13 are quite typical. The form of the orbit on this date in terms of latitude, altitude and local solar times is shown in Fig. 1. Successive orbits will repeat this picture with progressive displacement in longitude of 25° per orbit, thus enabling ionization density at different longitudes to be compared for the same latitude, altitude and local time.

Fig. 2 shows the oblique profile of ionization density through the geocentric altitude-range of 400–1,000 km for four successive orbits in the northern hemisphere in sunlight. Fig. 3 shows the return transit for each of these orbits, which is in the southern hemisphere during local night. It will be noted that the detail of the ionization density profile changes from transit to transit due to the complex dependence on longitude already mentioned, but on each transit an ionization ledge is encountered. This ledge appears as low as at 700 km geocentric altitude during the day, and surprisingly at a higher altitude of 1,000 km near local midnight.

The combined results from all the orbits so far analysed are shown on Fig. 4 in which the altitude of the new layer is shown as a function of local solar time. Fig. 5 shows the ionization intensity of the maximum of the layer also as a function of local solar time. The spread in both these parameters is the result of the geographic and temporal complex variations of ionization, and is not indicative of instrumental errors.

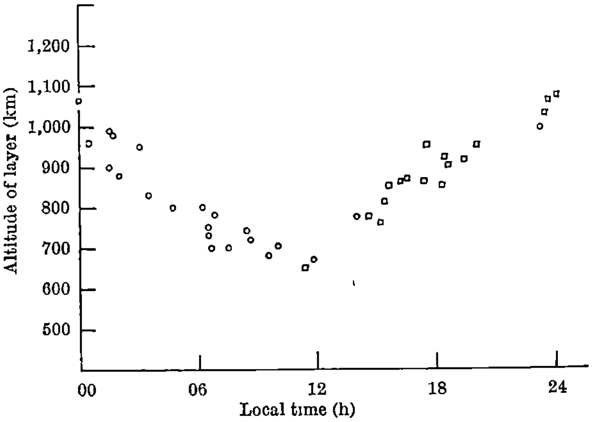

Fig. 4. April 30–July 1, 1962. O, Northern hemisphere; □, southern hemisphere

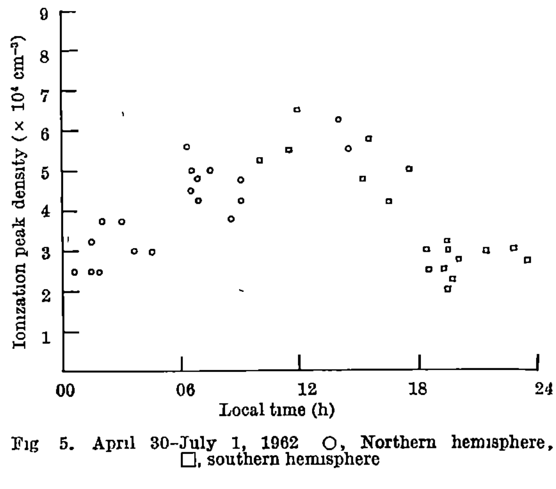

Fig. 5. April 30–July 1, 1962. O, Northern hemisphere, □, southern hemisphere

We conclude, therefore, that the departure from diffusive equilibrium in the Earth's gravitational field which these results indicate is very surprising and indeed it will be difficult to find any mechanism which could produce such a layer. A diligent search has been made for possible instrumental defects which could account for the observations of departure from diffusive equilibrium, but none has been found. Figs. 4 and 5 include data for the full range of latitude and longitude in both northern and southern hemispheres, and so the systematic nature of the results is well established.

A layer of ionization above the F_2 region should be readily detected by a suitable topside sounder experiment using a high-altitude rocket or satellite. The first such experiment has been reported by Knecht, Van Zandt and Russell[8] using a rocket-borne topside sounder from Wallops Island at 18.17 h on June 24, 1961. The topside sounder in this experiment operated at two fixed frequencies, namely, 4.07 and 5.97 Mc/sec. These frequencies are both far above the critical penetration frequency for the new layer and so no regular reflexions could have been recorded. It is, however, very interesting to note that scatter echoes of large intensity were recorded at various altitudes in the range 700–1,000 km and these effects were not at the time understood. The effects observed are consistent with the existence of a layer having deep spatial irregularities as is now proposed. The most intense of the scatter echoes occurred at an altitude of 840 km and this is the altitude at which the peak of the new layer has been found by *Ariel* at 18.00 h local time corresponding to the topside sounder experiment.

A second, similar topside sounder experiment was conducted from Wallops Island by Knecht and Russell at 23.26 h on October 13, 1961. The peak altitude of the rocket carrying this experiment was 1,070 km. This is near to, and may indeed be below, the altitude of the new layer at local midnight since there may be some seasonal variation in the layer altitude. It is therefore not inconsistent that no similar anomalous scatter was recorded on this flight.

We thank the U.S. National Aeronautics and Space Administration (NASA) for providing the satellite, its power supplies, sequence timing, telemetry, data encoding and launching into orbit. We also thank NASA for data decoding and for providing 'quick-look' print-out of data which has made this early presentation of results possible.

RADIATION HYGIENE IN AND AROUND A NUCLEAR POWER STATION

By DR. J. H. MARTIN

Health and Safety Manager, U.K. Atomic Energy Authority,
Chapelcross Works, Annan

THERE are installed at Chapelcross four of the Calder Hall type of nuclear reactors. Construction of the station commenced in 1955 and the first of the reactors reached power in January 1959 and the fourth in April 1960. Apart from laboratory provisions for technical investigations concerned with the reactors and research in health physics, Chapelcross, in essentials, differs little from the nuclear power stations which are being built for the South of Scotland Electricity Board and the Central Electricity Generating Board. Since also, unlike Calder Hall which is closely integrated with Windscale, it is not associated with other atomic energy operations, the performance of Chapelcross from many aspects, including that of radiation hygiene, serves as a useful pointer to what may be expected from these power stations, and it is the purpose of this article to present the experience of its operation in relation to radiation safety.

Staffing

On the Works control side of the Health Physics Department, as distinct from its research activities, there are four professional physicists, three chemists, and two ancillary staff. These are supported by a team of twenty-four industrial staff who have been selected and trained to operate and interpret health physics instrument readings and to apply the information in the control of operations involving sources of radiation. These men, who are described as health physics monitors, provide, in shifts, round the clock coverage of all operations. To round off the picture, although it is not of direct concern in this article, industrial safety, as distinct from radiation safety, is covered by a safety officer, a safety foreman and five firemen.

Site Control and Experience

The basic cycle of operations at Chapelcross involves charging a reactor with the 10,000 fuel elements which the core contains, then running it at power for a suitable period. At the end of the period selected, some or all of the elements are removed from the core into shielded flasks which form part of a discharge machine. Each flask contains a magazine or 'basket' holding twenty-four elements and these are transferred from the discharge machine on the pile cap, down a shielded shaft to a transport flask, inside which the basket is contained while being transported to the cartridge cooling pond. Here the flask is lowered under water and is unloaded at a depth of some 18 ft. The elements unloaded are then transferred by remote-control grabs into small containers called skips, which hold some 150 elements. The elements are stored in these skips, under water, for a suitable period to allow the more short-lived radioactivity to decay. The skips are then removed from the pond, placed in another transport flask on a large semi-trailer and moved by road to Windscale where the elements are processed for separation of plutonium and recovery of uranium

Over and above these basic operations there is a number of operations which take place, not all of which are connected with the primary functions of Chapelcross for the production of plutonium and power For example, facilities are provided in the Chapelcross reactors for testing of different designs of fuel elements and for experimental work on graphite Many of these experiments require the application of non-standard techniques for inserting and removing from the reactor the materials being tested and for their subsequent handling and examination All these operations, whether they be routine shutdowns or for special purposes, are the subject of careful planning in advance and detailed instructions are prepared to cover each operation. At this stage and particularly for special operations, a professional member of the health physics staff will be a party to the discussions

The removal of items from the reactor, some of which, like fuel elements, contain many thousands of curies of activity, their transport about the site and their movement in and out the pond involve a potential risk of someone being exposed to radiation directly In addition, the accidental release of gas from the reactor, the dropping or scraping of materials such as graphite, the splashing of water in and around the pond, together with maintenance work on apparatus associated with the reactors or with radioactive material, involve the risk of air and surface contamination Elaborate installed alarm systems are in operation to assist in warning personnel of the occurrence of such incidents, but the most effective control is provided by the health physics monitor staff, who make measurements of the radiation-levels at all stages of such operations

While the reactors are in operation there are inevitably, despite heavy shielding, small fluxes of γ-rays, and in some instances neutrons, at various locations around the reactors For example, a quantity of the short-lived argon-41 is produced by (nγ) reaction in argon impurity present in the carbon dioxide coolant gas used in the reactors while by (np) reaction on oxygen nitrogen-16 is also produced The half-life of the latter is only 6 sec, and while therefore there are moderate fluxes due to this isotope at the top of the heat exchanger, by the time the gas has reached the bottom the activity-levels are negligible Because, however, of their fairly energetic γ-rays (1 3 MeV and 6 1 MeV respectively) these isotopes are the principal source of γ-ray background in the neighbourhood of the reactors.

In addition to those present on and around the reactor during the course of their normal duties a good deal of maintenance work, work in preparation for a specific operation and investigations and experimental work is carried out while the reactor is operating Once again these operations or investigations are the subject of careful planning and of surveys and estimates by the health physics department of the radiation-levels in the region concerned

The maximum permissible exposure to external radiation in any one week is 0 3 rads, and the integrated dose received by an individual is governed by the fact that he must not receive more than 3 rads in any period of thirteen weeks, and further, that the dose accumulated in his lifetime must not exceed that expressed by the equation dose = $5(N - 18)$ rads, where N is the age of the individual in years The average exposure-level which this latter equation permits is 0 1 rads a week assuming continuous exposure throughout a working life from the age of eighteen This corresponds to 0 02 rads per day for a five-day week and 2 5 mrads/h for an 8-h day.

When personnel are called on to work in areas where levels are likely to exceed 2 5 mrads/h, monitors exercise special control and they are authorized to determine a working time such that a man may receive up to 0 02 rads A charge-hand monitor can authorize exposure up to the 0 06 rads level Subject to the individual or individuals concerned having satisfactory radiation records a member of the professional health physics staff may authorize an exposure up to 0 2 rads Permission for greater exposures to individuals must be obtained from the Health and Safety Manager This detailed control of operations on site is backed by continuous monitoring of all personnel on the site, who must carry film badge dosimeters

Film badges are normally worn for a period of one month although special issues are made to cover specific requirements In addition, where the radiation-level in which personnel are to work exceeds 2 5 mrad/h, control of the exposure of personnel by stipulation of working times is augmented by the issue of quartz fibre electrometers which can be read directly, and thus the dose received can be checked at intervals while the work is in progress Where the monthly film badge records a dose exceeding 0 4 rads (that is, greater than an average weekly exposure of 0 1 rads) the circumstances surrounding the receipt of this exposure are investigated and where the exposure has been caused by failure of the individual to obey instructions or errors in operating conditions, steps are taken to rectify these The Health and Safety Manager reports these circumstances to the Board of Management monthly

The results of analyses of the personnel dose records for a year with the station operating at full power are shown in Figs 1 and 2 and Tables 1 and 2 Approximately 1,000 people are employed, and the histograms in Figs 1 and 2 show the distribution of the integrated dose per annum and the dose per man per annum in various work categories on the site It is an interesting feature of a more detailed analysis of these records that, contrary to what might be expected at first, operations involving the charge and discharge of a reactor when large quantities of very active material are being moved about the site are not the principal cause of exposure of personnel In fact the charge/

discharge teams who carry out these operations on the reactor receive lower exposures during the periods of charge/discharge than they do when carrying out other duties around the reactors while they are at power. During these charge/discharging periods, however, workers at the ponds, where all the irradiated fuel elements are being handled, and health physics monitors, tend to receive more radiation. During reactor operation small quantities of radiation are received by staff operating the reactors, by process workers carrying out normal duties around the reactor and by maintenance staff servicing equipment on and about the reactors. As mentioned previously there is in addition to the γ-ray flux around the reactors a possibility of small neutron fluxes. The film badges carried by personnel incorporate a cadmium filter and the (nγ) reaction induced by slow neutrons makes it possible to measure these by use of the blackening of the film under this filter. Appropriate personnel have also been issued with track plates for detection of fast neutrons. The exposures found in both cases have been extremely small. The threshold for the fast neutron plates is 50 mrem and this has been exceeded on one occasion only. The threshold for measurement of slow neutrons is 10 mrem and the highest dose recorded for the year was 130 mrem.

Throughout the history of the station there have been increasing amounts of power generated in succeeding years resulting in an increase in the radiation-level in the vicinity of the reactors. Between 1959 and 1960 this was principally due to the coming on to load of each of the four reactors in turn. However, in the period 1960–61 the increase has largely been due to technical improvements in reactor operation. The Calder Hall–Chapelcross type of reactor was designed for a thermal power output of about 180 MW, and over the years this has been raised to a figure of over 240 MW. It will be seen from Tables 1 and 2 that very satisfactory control of the personnel exposure situation has been achieved and that despite increased power the average exposure of individuals on site per unit of power produced has been held down.

During charge/discharge operations on the pile cap and at the pond there are always slight possibilities of air and surface contamination, and health physics monitors carry out regular air sample surveys as a routine, and monitor personnel on the completion of the work. The protective clothing worn in these circumstances varies a little with the duties being undertaken, but it is simple, comprising, for example, a coverall (boiler-suit), cloth overshoes and cap. There are also other operations which may result in contamination of personnel or of the air they breathe. Examples of this type of work are entry made into the heat exchangers and other parts of the gas circuit for maintenance and inspection work and experimental work carried out on graphite specimens which have been irradiated in the reactors. For such operations more elaborate types of protective clothing, sometimes with separate air supply to the operator, are used, and special air sampling surveys are made. Table 3 shows the results of air sampling for the year 1961, and it will be seen that contamination-levels exceeding maximum permissible concentration are rare. Cases where air contamination occurs unexpectedly are rare and it is unusual for personnel to be contaminated in these circumstances. Contamination of personnel therefore generally arises through disregard of working instructions or through lack of care in undressing from contaminated clothing. During 1961 only twelve cases of contamination had to be sent to the surgery for decontamination, none of these being serious. To ensure that there has been no inhalation and ingestion of radioactivity or absorption through the skin, it is a routine to take urine samples in these instances and to analyse them for fission-product activity. In all cases the findings were negative.

Table 3 AIR SAMPLING RESULTS

	Total No. of samples	No. and per cent above 0.3 m.p.c.	1.0 m.p.c.	10 m.p.c.	Highest result
Routine	15,656	32 0.2 per cent	12 0.08 per cent	Nil	8.9 m.p.c.
Special	34	7 20.6 per cent	3 8.3 per cent	Nil	6.9 m.p.c.
Special (conditions where breathing apparatus has to be worn)	512	261 51 per cent	173 33.8 per cent	46 9 per cent	261 m.p.c.

A high standard of plant cleanliness is maintained by close checking by monitors of the incidence of air and surface contamination and control of the movement of contaminated material. Potentially, contaminated equipment is checked by swabbing, the swabs being assessed for activity. A measure of the success of this control is the fact that both pile cap and pond areas as well as all other regions of the reactors are 'clean' areas when charge/discharge operations are finished and access to them is thus not limited by any considerations of radioactive contamination. Table 4 shows the results of work carried out in maintaining this level of cleanliness.

Table 4 SURVEYS FOR SURFACE CONTAMINATION

Total No. of surveys	1,151
No. showing no contamination above M.P.L.	1,117
No. showing contamination above M.P.L. in a few places	32
No. showing contamination over large areas	2

In maintaining the standards outlined above it is not sufficient to rely solely on the control procedures and personnel alone, and training of operating personnel has an important part to play. All personnel on joining the establishment receive training in radiation safety and supervisory personnel spend a period of time in the Health Physics Department seeing the variety of ways in which the Department assists in maintaining good standards. Regular refresher courses in, for example, "Prevention of Contamination" are run so that personnel act always with a consciousness of the possible existence of a radiation hazard.

Environmental Safety

Small quantities of radioactive effluent are discharged to the environment in two ways. The main radiation absorbing or 'biological' shield of the reactor is cooled by blowing air past it. This air is drawn in near ground-level and is ejected from two 250-ft stacks, one on each side of each reactor. The air passes through a region inside the biological shield where there are substantial neutron fluxes, and a certain amount of induced activity is produced in the air. This is principally the short-lived isotope argon-41. The second source of low-level radioactivity is the cartridge cooling ponds. In the course of operation of these ponds, a small quantity of radioactivity gets into the cooling pond water as a result of corrosion of the canning material of the uranium elements, in which some activity has been induced or by leakage from the uranium to the water through the canning material or occasionally because damaged elements are in the water. The capacity of each of the two cartridge cooling ponds is 400,000 gallons of water, and some 6 per cent of the volume of a pond is discharged to the Solway Firth each day. Water to be discharged is transferred from the ponds to a detention tank, where it is held until discharge time, which is between high tide and high tide plus 2 h. Between the ponds and the detection tanks a filter system is provided for removal of any particulate activity. While in the detention tanks the water is sampled and measured for activity before discharge is permitted. Discharge of liquid and gaseous effluent is carried out under authorizations granted by the Secretary of State for Scotland. That for liquid effluent authorizes discharge, in the period at high tide as stated above, of up to 22.5 curies every 3 months of total $\alpha + \beta$ activity, this activity to contain no more than 112.5 millicuries of strontium-90. A further proviso is that the discharges should be made as uniformly as is reasonably possible. Records of the quantity of radioactive liquid effluent discharged are supplied regularly to the Scottish Home Department.

An example of the performance of Chapelcross in this respect is shown in Fig. 3, where the records for the total $\alpha + \beta$ activity discharged over a period of time are shown. Considerable variations are apparent between periods when all reactors are operating and those when discharge operations are in progress and the ponds contain large quantities of fuel elements, but, overall, the average discharge level is something less than 10 per cent of that authorized.

It is a further requirement of the granting of permission to make these discharges that the station carries out a survey of various biological materials in the region around the site, to ascertain whether any potentially injurious levels of radioactive material are occurring as a result of the discharge operations. In the early period of operation of nuclear energy installations, partly because the scientific information on which to base an environmental sampling programme was somewhat sketchy, but very largely to establish public confidence, considerable amounts and varieties of biological material were collected and assayed for their radioactive content although the scientific justification for a good deal of this work could not be established. Initially, in the land area surrounding Chapelcross, samples of grass, root, mat, soil, milk and reservoir and rain-water were collected at intervals varying from four to six weeks, and analysed for their total α and total β content, and in the cases of milk and water specifically for their strontium-90 content. Measurement of the γ-ray background-level was also made at 31 points within a radius of 9 miles of the site.

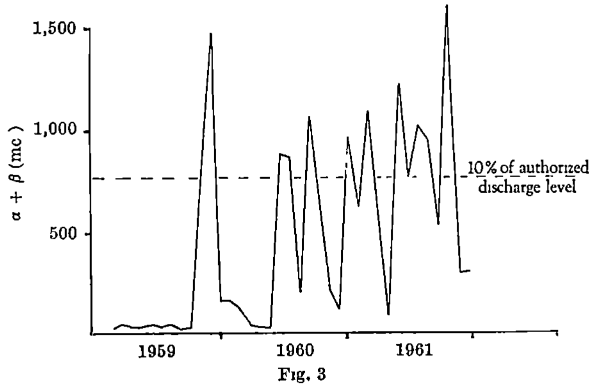

Fig. 3

The primary objective of an environmental monitoring programme is to check that the public health is not endangered, and there is now ample evidence to show that, in most cases, the principal potential hazard to members of the public from radioactive materials released into the environment arises from the ingestion of contaminated food or water. It follows, therefore, that the aim should be to obtain information on the level of contamination of the diet and that the measurements taken should be capable of being related to a maximum permissible level in some item of human diet. In some cases it may be possible to extend the surveys to provide scientific information on the behaviour of radioactive materials in the environment, as has been done by studies of fall-out, but it is important to maintain the distinction between the scientific function and that of assurance of satisfactory operating conditions.

Recently, in consultation with the Department of Health for Scotland, the Agricultural Research Council and the Radiological Protection Division of the Authority Health and Safety Branch, an environmental monitoring programme, based on the foregoing requirement, was agreed.

Accumulation of data has revealed that, in the circumstances pertaining at Chapelcross, the item of the human diet which would convey the largest amount of radioactivity into the human body is milk. Accordingly, although for other reasons γ-ray measurements are still made at a number of points, monitoring cover in relation to gaseous effluent is provided by milk sampling, the samples being analysed for iodine-131 and strontium-90. An example of data from the original surveys is shown in Fig. 4. Large variations, due to variations of the natural activity of the air, will be seen in the measurements of α-activity on grass. Broadly speaking, the activity on grass rises in the winter time when heavy rain brings down the natural α-activity from the air, and since the grass is growing relatively slowly a large quantity accumulates on a small quantity of grass. At other seasons of the year more rapid growth of the grass means less activity per unit weight and, of course, the decreased rainfall means less precipitation. It is, clearly, unrealistic to expect a measurement of the gross α-activity in these circumstances to have any value as an insurance that the Station is not releasing undue radioactivity to the environment. Milk sampling is undertaken from two groups of farms, one group being within a radius of 3 miles

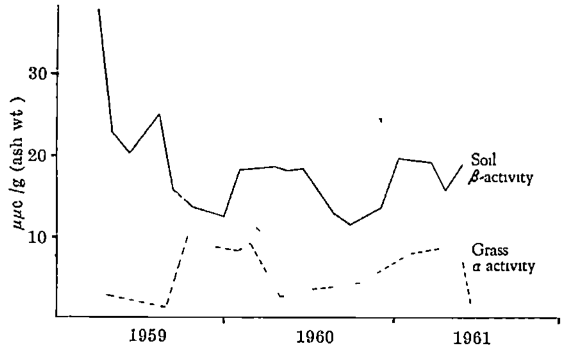

Fig 4

and the other between 3–5 miles from the station The results of analyses of milk for iodine-131 and strontium-90 are shown in Figs 5 and 6 The minimum level of activity of iodine-131 which can be measured is 20 μμc /l, while the maximum permissible concentration as specified by the Medical Research Council is 400 μμc /l

In the case of strontium-90 the maximum permissible concentration specified by the Medical Research Council is 400 μμc /ml, and as the calcium content of the milk in the Chapelcross area varies only a few per cent above and below 1 g/l, the s u values shown in Fig 6 are almost exactly the values in μμc /l Although the actual levels found are affected by the use of supplementary feeding in winter conditions, the rise in iodine-131 activity towards the end of 1961 is due entirely to fall-out from Russian atom bomb testing, and it parallels similar results reported from all over Britain A corresponding rise in the strontium-90 figures is expected in the spring of 1962 Fig 7 shows the results obtained at one of the standard points of γ-ray measurements made regularly since just before the Station commenced operation Once again the only effects which can be detected are those due to fall-out, there being a decrease following the cessation of weapon testing, and a rise at the end of 1961 due to the latest Russian series of tests

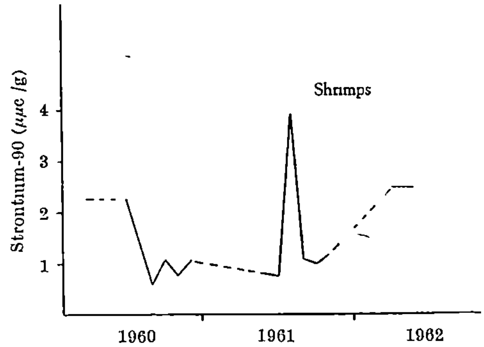

Fig 9

A similar survey programme on and in the Solway Firth is carried out in relation to the discharge of liquid effluent Here samples of sand, seaweed, shrimps, salmon, etc , are collected and analysed for activity

Sand sampling is carried out to ensure that no external radiation hazard to people using the beaches will result, while seaweed is looked at because of its potential use in making lavar bread, although the variety used for this is practically non-existent in the Solway region A large part of the British market for shrimps is supplied from the Solway area, and it is important, therefore, to measure their activity In the grounds fished, shrimps are only available between spring and late autumn Salmon fishing is an important industry in the area of the Solway, and while, because of their wide ranging habit they are of doubtful value as a monitor of the effect of discharge of effluent, salmon are taken for analysis

Examples of the results of such surveys are shown in Figs 8 and 9 In all cases the levels of activity involved are very low, and no variations due to the operation of the station can be detected Because of the difficulties and time involved in separating the flesh of the shrimp from the shell, the whole is ashed and analysed The variations of strontium-90 activity recorded are thought to be associated with the shedding of the exoskeleton, the exact timing and frequency of which are unknown

It will be seen that by proper training of staff and by intelligent use of control measures, a nuclear power station can be operated without personnel receiving unacceptable levels of radiation exposure Further, the small quantities of radioactive effluent which arise from the operation of a nuclear power station and which are discharged to the environment have no detrimental effect on that environment or on those occupying it or using its products

CONVECTION IN THE MOON

By Prof S. K. RUNCORN

Department of Physics, King's College, Newcastle upon Tyne, and Jet Propulsion Laboratory, California Institute of Technology, Pasadena

RECENT investigations of terrestrial continental drift[1] raise the possibility that convection currents exist within the Earth's mantle This supposes that the Earth's mantle, except for a thin surface crust, has zero-strength and also the properties of a Newtonian fluid for stresses of periods of some millions of years, a hypothesis which seems to receive support from solid-state physics[2] A stumbling block, much emphasized by opponents of convection theories, is provided by the fact that the figure of the Moon departs from a sphere by amounts up to thirty times more than if it were in hydrostatic equilibrium This has been held to show that it has considerable long-term strength The non-equilibrium shape of the Moon, however, may simply mean that convection also exists within this body

The hydrostatic theory of the figure of the Moon predicts a bulge towards the Earth due to tidal forces of about 60 m and an equatorial bulge due to its monthly rotation a quarter as large The bulge towards the Earth can be determined from the comparison of the apparent motion of points on the Moon's surface due to the geometrical librations Baldwin[3] shows that the radius towards the Earth exceeds the mean value in the plane of the sky by 1 9 km. Whether the limb of the Moon departs from circular shape has not yet been determined because of difficulties arising from surface relief and irradiation However, the motion of the Moon allows its moments of inertia to be determined about its polar axis, the Earth–Moon axis, and the third axis with high accuracy Their differences greatly exceed those calculated on the hypothesis of hydrostatic equilibrium It is convenient to express this in terms of a triaxial ellipsoid of uniform density The bulge towards the Earth is then found to be 1 km and the polar flattening 0 6–0 7 km Because of the irregular surface, Baldwin's method might be thought to be inaccurate yet he obtains a bulge essentially twice the dynamically determined one whether he relies on points on the maria or on the uplands This strongly suggests that the Moon has a systematically lower density beneath the bulge

It has long been assumed that the departure of the figure of the Moon from that appropriate to a body in hydrostatic equilibrium implies considerable internal rigidity To support a bulge of 1 km, a stress difference of about 20 bars at the centre is required, as was shown by G H Darwin As it was until recently thought that the Moon and Earth were once liquid, and cooled and solidified in the early history of the solar system, it seemed to follow that the non-equilibrium shape was acquired of the order of 10^9 years ago and was frozen in, either, as Laplace thought through inhomogeneous cooling, or as Jeffreys[4] once supposed as a fossil-tide raised on the Moon when it was much closer to the Earth By Kepler's third law, the angular velocity of rotation of the Moon, assuming it to have been then, as now, a synchronous satellite, would be inversely proportional to the three-halves power of the Earth–Moon distance Thus, the bulge due to rotation would have been proportional to the inverse cube power, and therefore proportional to the tidal bulge itself Thus, the explanation of the non-equilibrium shape as a fossil tide must be abandoned, for the ratio of the polar flattening to the earthward bulge is 0 6–0 7, not 0 25

It is easily shown that convective motions cause a slight rising of the surface above the hot uprising current In the theory of convection in a spherical shell under a radial gravitational field[5], it is convenient to develop the velocities of flow and the temperature- and density-perturbations in spherical harmonics From their orthogonal properties, it can be simply shown that only convection described by harmonics of second degree are effective in producing the required differences in the moments of inertia Such a convection pattern, if axially symmetrical, consists of two cells hot fluid rising from the interior of the sphere along its axis and descending, after cooling at the surface, along the great circle 90° away from the axis Therefore, the bulge towards the Earth, determined by Baldwin, can be explained by a second-degree convection current with its axis of symmetry directed towards the Earth Because the moments of inertia about the polar axis and the equatorial axis in the plane of the sky are unequal there must be superposed on this pattern an exactly similar one symmetrical about the latter axis, with velocities 0 6–0 7 of the former

Chandrasekhar[5] shows that the ratio of the inner to the outer surfaces of the spherical shell, in which convection is occurring, and the nature of the bounding surfaces determine the degree of the spherical harmonics describing the convection which occurs at marginal stability. To account for convection of second degree would require the presence of a core with radius lying between about 0.06 and 0.36 of the lunar radius. These values[6] emerge for the case of a spherical shell with a rigid outer boundary and a free inner one. The low temperature and consequent rigidity of the outer crust of the Moon make the former condition realistic. The latter assumes that the core is of iron, which, as it has a lower melting-point than the silicates surrounding it, may be fluid. It seems reasonable to suppose that the iron has been concentrated towards the centre in the Moon as in the Earth by convection[1]. The closeness of the mean density of the Moon to that of olivine suggests that the proportion of iron is lower than in the Earth, a conclusion not in conflict with the existence of this small iron core (0.2–4.6 per cent of the total volume).

Equating the pressure in the uprising and downgoing convective columns, and assuming a coefficient of volume expansion for olivine of 2×10^{-5} per °C, the 2-km bulge towards the Earth implies differences in temperature driving the convection of about 50° C. Such a theory would explain the discrepancy between the dynamical and the optical determinations of the height of the bulge.

In both the Earth and Moon, convection would bring about an equilibrium between the total heat internally generated and that being conducted out through the surface. As the mantle of the Moon and Earth are of the same composition, probably similar to chondritic meteorites, it is reasonable to suppose that the radioactive heat generated per unit volume is the same. The heat-flow out of the Moon will therefore be one-quarter of that through the Earth's surface, that is, 2×10^{-7} cal/cm^{-2}/sec^{-1}. The heat carried by a convection current is proportional to the velocity and temperature differences. As I have shown[6] the latter in the Earth are only $\frac{1}{3}$° C., the velocity of the currents in the Moon must only be 0.02 of those in the Earth, that is, about 2 cm/yr. As the mean density of the Moon and the Earth's mantle are in the ratio of 3:5 and the gravity of the Moon and Earth in the ratio of 1:6, the buoyancy forces driving the convection in the Moon will be fifteen times greater than in the Earth, for the temperature differences are 150 times as great. Similarly, because the Earth is four times as large as the Moon, the viscous forces resisting convection, if the coefficients of viscosity were the same, would be a third of those in the Earth. Therefore, the viscosity of the Moon must be about 50 times that of the Earth's mantle, presumably the result of the lower pressures and temperatures in the Moon.

OBITUARIES

Sir Ronald Fisher, F.R.S.

SIR RONALD AYLMER FISHER died suddenly at Adelaide on July 29 in his seventy-third year, following an operation. His death is a grievous loss, both to his many friends and to science.

Born on February 17, 1890, the seventh child of G. Fisher, of Robinson and Fisher, auctioneers, of St. James's, he was educated at Harrow and Gonville and Caius College, Cambridge, where he read mathematics, and for a further year held a studentship in physics, studying statistical mechanics, the quantum theory and the theory of errors. He then spent two years as statistician to the Mercantile and General Investment Co., followed by six years teaching in public schools; fortunately for the world, his extremely short sight prevented him from joining the Forces in the First World War.

In 1919 he was selected by Sir John Russell to fill the newly created post of statistician at Rothamsted Experimental Station. Already while at Cambridge he had developed a keen interest in Mendelian theory and its relation to the evolutionary principles of Darwin, and Rothamsted provided a congenial research environment and direct contact with practical biological and agricultural research. This proved a most happy combination, in that he rapidly came to appreciate the real requirements of biological research workers, who have to experiment on highly variable material and are severely limited in the number of experimental units—plants, animals, field plots—that can be included in any one experiment. This demanded, first, that statistical methods should be devised which would enable sound conclusions to be drawn from small samples, and secondly, that the treatments included in an experiment should be so chosen that the maximum amount of information is obtained on the points at issue. On the theoretical side, this quickly led Fisher to the development of exact tests of significance for small samples, and to the development of the theory of estimation, in particular the method of maximum likelihood and the principle of sufficiency. It also led to the recognition of the principles governing experimental design, and to the development of the analysis of variance, which, among its many uses, provides a convenient computational procedure for the estimation of the errors of experimental results and for testing their significance. The modern techniques of experimental design and analysis which flowed from this work have now been almost universally adopted not only in agriculture but also in all fields where experiments on variable material are required. The recent spectacular advances in agricultural production in many parts of the world owe much to their consistent use.

It has been part of Fisher's strength that he always endeavoured to make the statistical methods he evolved available to biologists and others who wish to apply them, and to give adequate insight into the principles without confusing the issue with the mathematics required for their derivation. To this end, after five years work at Rothamsted, he wrote *Statistical Methods for Research Workers*. This book (which has been greatly extended, though little altered, in successive editions) has had an immense influence in introducing modern statistical methods in biological research. *The Design of Experiments*, though not published until 1935, also flowed directly from his work at Rothamsted.

Although at Rothamsted Fisher was not directly concerned with genetics, he pursued his investigations privately, both on the theoretical side and in practical breeding studies on mice, snails and poultry; from the last he confirmed his theory of the evolution of dominance. *The Genetical Theory of Natural Selection*, published in 1930, contains ideas, particularly on human evolution, much in advance of its time. If these have as yet had little practical impact, it may be in part because Fisher's conviction of the power of genetic selection in moulding organisms to fit their environment led him to belittle the importance of reforms, such as improvements in nutrition, designed to improve the environment, and this enabled progressive thinkers to dismiss his theories on human evolution, which in any event they found distasteful, without serious thought. Nevertheless, the book did much to reconcile Darwinian and Mendelian theory.

Fisher's genetical interests led to his appointment in 1933 to the Galton chair of eugenics in the University of London. Here he became interested in blood groups, and in particular resolved the complexities of the rhesus system. In 1943 he became Arthur Balfour professor of genetics in the University of Cambridge, a post which he held until his retirement in 1957. Here he continued his theoretical studies on population genetics and quantitative inheritance, publishing *The Theory of Inbreeding*, and experimental studies on chromosome mapping in mice, and on polyploidy in *Lythrum*. He remained in Cambridge until his successor was appointed in 1959, and then took up work in Adelaide with the Commonwealth Scientific and Industrial Research Organization Division of Mathematical Statistics. After his formal retirement he became interested in the claim that had been made that cigarette smoking was responsible for lung cancer. Whatever the final verdict on this issue, Fisher's re-examination made apparent the weakness of the deductions from the original evidence, and provided an excellent example of the dangers inherent in the statistical analysis of survey material.

Throughout his life Fisher continued to develop his ideas on the fundamental problems of inductive inference and estimation. He early recognized the fallacies of the Baysian approach, and in 1930 introduced the concept of fiducial probability. Other mathematical statisticians have found great difficulty with this concept; but it will, I think, in due course take its place along with likelihood and exact tests of significance of small samples as one of Fisher's outstanding contributions to the theory of statistics. In 1956 he published *Statistical Methods and Scientific Inference*, in which he summarized his current thought on these problems and for the first time put forward the entirely novel concept of reference sets and recognizable sub-sets for defining probability.

Fisher was elected a Fellow of the Royal Society in 1929, receiving the Royal Medal in 1938, the Darwin Medal in 1948 and the Copley Medal, the highest award of the Society, in 1955. He was president of Gonville and Caius College, Cambridge, during 1956–59. He was knighted in 1952, and received recognition from many foreign universities and academies. In 1961 he was elected a member of the Pontifical Academy of the Vatican, an honour which gave him particular pleasure.

To those who knew him well, Fisher was a man of great charm, a brilliant conversationalist, cultured in the widest sense, and appreciative of historical values. He was also a most stimulating scientific colleague, as the many who have worked with him can testify. He did not believe in direction in scientific research—"I wonder how many of us do the work we're paid for '—and this, and his irascible temperament, made him a poor administrator. He was also, I think, unduly sensitive to much of the unjustified criticism which his work, because of its originality, inevitably attracted. This led him into many scientific controversies, which he pursued with vigour and apparent enjoyment, but often in that indignant frame of mind that leads to a partial view of the problem, and leaves unanswered objections that are obvious to the impartial observer. Indeed, his approach to scientific controversy was often that of an advocate rather than a judge, and this did frequent harm to many of the causes he had most at heart.

He married in 1917 Ruth Eileen, daughter of H. Gratten Guinness, and had two sons (the elder was killed in action as a fighter pilot in 1943) and six daughters.

F. YATES

Mr. G. A. Bacon

MR. GEOFFREY ARTHUR BACON, whose untimely death occurred on August 1, 1962, was born at Boxmoor, Hertfordshire, on May 25, 1918. He was educated at Berkhamsted School, and in 1938 joined the laboratory staff of the Royal Free Hospital in Gray's Inn Road, where he worked as personal assistant to Prof. R. A. Webb. The unit in which he worked was moved during the Second World War to the Three Counties Emergency Hospital, near Hitchin, Hertfordshire. In 1944 he joined the staff of Harlow Wood Orthopædic Hospital, Mansfield, where he became technician in charge of the Laboratory Emergency Pathological Service. He entered the Scientific Civil Service in 1947 and was appointed for duty as an experimental officer at the then Microbiological Research Department of the Ministry of Supply at Porton. He was promoted to the post of senior experimental officer in 1955. Throughout his service here he has worked entirely with pathogenic bacteria, initially in investigations of the relationship of nutrition to virulence in *Salmonella typhi* and afterwards, over the past twelve years, on the factors determining virulence in *Pasteurella pestis*. Largely through the devoted work of Mr. Bacon these factors, which initially were completely unknown, have now mostly been identified. This increase in our knowledge of the causative organism should permit a more rational approach to the future prophylactic immunization against plague than has been possible in the past. It is ironical, but by no means unprecedented in bacteriology, that one who had devoted such a substantial part of his working life to this end should have fallen victim to the disease he was helping to prevent in others. His death, however, has made us aware that we do not yet have a complete understanding of virulence and infectivity in this organism and that work on these subjects must continue. There is no doubt that Mr. Bacon was fully cognizant of the risks his work entailed, and these risks he willingly accepted.

Mr. Bacon was held in the highest regard by his colleagues. He may best be described as a gentle man who was always generous, kind and considerate and prepared to help others whenever possible His inventive skill applied to the improvement of laboratory techniques and apparatus was invaluable and possibly irreplaceable A safety pipetting device he designed to eliminate the hazard of aerosol production during pipetting operations has been in use throughout the Microbiological Research Establishment for the past ten years and no doubt has contributed to the excellent safety record of the Establishment

Mr Bacon's main interests outside his work were in his family, his new home and large garden and in the theatre The Salisbury Theatre Club and the Porton Musical and Dramatic Society have lost an ardent supporter, and the social life of the village of Whiteparish and of the Microbiological Research Establishment are the poorer by the death of Geoff Bacon Our sympathy is extended to Mrs Mary Bacon and to his daughters Elizabeth and Susan

T W Burrows

NEWS and VIEWS

U S National Academy of Sciences:

Foreign Associates

The following have been elected foreign associates of the U S National Academy of Sciences Prof E Amaldi, professor of experimental physics, University of Rome, Dr F Lynen, director of the Max-Planck-Institut fur Zellchemie, Munich, Sir William Penney, deputy chairman, U K Atomic Energy Authority, Prof R N Robertson, professor of botany, University of Adelaide

The Second Swinburne Award in Plastics

Dr J C Swallow

Dr John Cuthbert Swallow has been awarded the second Swinburne Medal by the Council of the Plastics Institute for his contribution to the discovery and development of polythene Dr Swallow was educated at the Universities of London and Leyden He joined Brunner Mond as a research chemist in 1924 and was in charge of polythene development work from the discovery to the building of the plant He became research manager of Alkali Division of Imperial Chemical Industries Ltd in 1941 and was appointed research director of the Plastics Division in 1942 Dr Swallow became managing director of the Plastics Division in 1951 and he has been chairman since 1952 Dr Swallow will deliver the Swinburne Award Address at the Royal Institution, 21 Albemarle Street, London, W 1, on November 12, when he will also be presented with the gold medal and the sum of money which accompanies the award The award, which has been endowed by Bakelite Ltd, was instituted in 1959 to commemorate Sir James Swinburne, who died at the age of 100 in the previous year The trust deed specifies the following terms of reference for the award " . to promote the advancement and diffusion of (*a*) the science and technology of plastics and of plastics engineering, and (*b*) science and technology in any field relating to plastics or to plastics engineering by making the award to persons who shall have made an outstanding contribution to such science or technology" The first award was made to Prof G Gee in July 1960

Harry Govier Seeley

Many interesting papers have appeared in the *Bulletin of the British Museum (Natural History)* and not least is one on "Harry Govier Seeley and the Karroo Reptiles" by Dr W E Swinton (3, No 1 Pp 1–39 London British Museum (Natural History), 1962 13*s*) The account of the life and activities of Seeley is an indication of the enormous energy and output of this remarkable man But Dr Swinton was especially fortunate in obtaining permission to publish a series of characteristic letters that Seeley wrote when he was in Africa They constitute a record of great historical and geological interest and throw much light on some of the fundamental fossils in the story of reptilian and mammalian evolution In addition there are interesting glimpses of life in South Africa in the latter part of the past century The paper also contains reproductions of some of the anatomical sketches by Seeley Dr Swinton was the obvious author for such a historical sketch and it was fortunate that he was able to complete the work before he went to Canada

The Panchromatograph

A new instrument for use in research and chemical analysis, the panchromatograph made by W G Pye and Co, Ltd, Cambridge, separates a mixture of liquids or gases into their component parts and gives a measure of the concentration of each The basis of operation of the panchromatograph is that a sample is fed into a column packed with special material and carried through in the stream of inert gas Separation is achieved so that the component parts of the sample emerge at intervals and are measured by a variety of detecting and recording systems The analyser unit is the result of extensive study of modern chromatographic requirements and has been designed to accommodate new advances of technology as they occur It is applicable to all analytical problems Columns and detectors are housed in separate ovens, both temperature-controlled to precise limits by electronic proportional counters The column oven is 42 5 × 28 × 16 cm and is of low thermal inertia construction A wide variety of columns can be accommodated The choice of column size and length is governed by the resolving power required by a given sample For the majority of applications 1 5 metre or 2 7 metre long, 4 mm diameter, glass columns are recommended Metal columns in lengths ranging from 0 3 to 6 m are also available The column units may be rapidly exchanged The detector oven is 23 × 23 × 16 cm and accommodates flame ionization, micro-argon ionization, macro-argon ionization, electron capture, photoionization, cross-section ionization, hot wire gas density and thermal conductivity detectors, together with the experimental triode ionization and electron mobility detectors An important feature is that any two detectors can be accommodated, allowing simultaneous use

The panchromatograph has applications in many fields, including medical research, petroleum refining, drug manufacture and food processing Separate pamphlets, obtainable from W G Pye and Co, Ltd, York Street, Cambridge, give details of the various accessories and the numerous applications

Management Science

DEVELOPMENTS in operational research and other sciences in management have been so rapid that it is not surprising to learn that the abstracts published by the International Literature Digest Service now run to 63 pages (*Operations Research/Management Science*, 2, No 1, 1962 75 dollars annually Published by Interscience Publishers Inc, 250 Fifth Avenue, New York 1, N Y Copies are available in the U K from Interscience Publishers Inc, 88–90 Chancery Lane, London, W C 2) Among the many sections are topics dealing with the management and conduct of operations research and related functions, optimal allocation, queueing, game theory, simulation models and Monte Carlo techniques, miscellaneous mathematical methods, probability and statistics and other methodology or special models

Ultra-sonic Cleansing

THE British Launderers' Research Association has continued work on a laboratory scale on the application of ultra-sonic or sonic energy to the cleansing of soiled fabric With the use of a piezo-electric type of transducer formed in the shape of a hollow roller, it has been found feasible to clean artificially soiled fine cotton fabric It is first soaked in a hot soap/metasilicate solution for 3 sec, mangled to remove excess moisture and then exposed to the sonic radiations for one second in a bath of cold soap/metasilicate solution The exposure times used make it possible to run the fabric round the transducer roll at speeds in the region of 100 ft per min Thicker fabrics require higher power per unit area to achieve the same degree of cleansing The energy supply has been taken from a General Electric Company valve generator and investigations are being made into the alternative use of a motor-driven alternator for producing electrical energy at a higher efficiency and at a lower cost Although at present there is no suggestion that ultrasonic or sonic energy could supplant the methods developed with the continuous processing machine, the results being achieved are sufficiently encouraging to warrant a continuation of this experimental programme It may well be that some form of ultrasonic cleansing will find a useful application in the removal of small areas of resistant soiling that might be left on an article after it has passed through a high-speed continuous-washing processing machine rather than return the article for a normal re-wash (Annual Report for the year 1960–61 Pp 32 Hendon, London British Launderers' Research Association, 1962)

Addiction-producing Drugs

CONTINUING its work of advising on notification, the World Health Organization Expert Committee on Addiction-producing Drugs recommends in its twelfth report exemption from the provisions of international control for oxpheneridine, (−)-3-hydroxy-*N*-propargyl-morphinan, metethoheptazine, metheptazine, and two preparations of diphenoxylate (*Technical Report Series* No 229 Pp 16 Geneva World Health Organization, London H M S O, 1962 1 Swiss franc, 1*s* 9*d*, 0 30 dollars) Four diphenoxylate preparations having now been recommended for exemption, the Committee considers it appropriate to propose a general exemption for such preparations provided they contain not more than a certain concentration of diphenoxylate On the other hand, noracymethadol is considered to be an addiction-producing drug comparable with morphine, while nicocodine and the four compounds designated by the committee as nethadone-intermediate, moramide-intermediate pethidine-intermediate-*A* and pethidine-intermediate-*B* are all found to be convertible into addiction-producing drugs and therefore subject to the relevant provisions of international control Concern is expressed about continuing traffic in heroin In some areas, limitation of the use of opium appears to have encouraged opium addicts to turn to heroin, which has been more readily available The controls on the illicit production of heroin and on the traffic in this drug need to be enforced more strictly Much stress is laid by the Committee on the necessity for providing the medical profession as early as possible with complete and accurate information on the addiction-producing and habit-forming properties of new drugs and on their therapeutic properties The further development of media for disseminating such information should be encouraged. The Committee noted that the Single Convention of Narcotic Drugs, drawn up in 1961, affords the World Health Organization the opportunity to initiate the examination of dangerous drugs and to adapt the extent of control to the degree of hazard to public health

Venereal Diseases and Treponematoses

IN 1961 the World Health Organization undertook a survey on the incidence of syphilis and gonorrhœa Thirty-one countries reported an increase of early infectious syphilis and 30 an increase of gonococcal infections between 1957 and 1960 The increase in syphilis in 1960, as compared with 1959, amounted to 19 per cent in Canada, 30 per cent in England and Wales, 45 per cent in the United States and 85 per cent in Denmark A similar increase was reported in other parts of the world Thus, in many countries, despite settled conditions, good health services and potent drugs, syphilis and gonorrhœa are again becoming a cause of concern to health administrations In the failure to control gonorrhœa, the gradual development of resistance of the gonococcus to penicillin in some countries and to streptomycin in others is significant, but probably not of basic importance Research carried out under auspices of the World Health Organization at the Gonococcus Centre of the Statens Serum-institut, Copenhagen, indicates that cases reported as 'resistant' are more often due to rapid re-infection than to gonococcal resistance to the drugs used (*WHO Chronicle,* 16, No 6, June 1962)

Activities against yaws continue to be aided by the Organization and by the U N International Children's Emergency Fund It is estimated that, since 1948, almost 280 million people have been examined and some 36 million people treated with long-acting penicillin in mass campaigns in Africa, the Americas and Asia, assisted by the World Health Organization The prevalence of clinical yaws has fallen in some countries from more than 10 to less than 0 5 per cent with a relatively small proportion of seroreactors in the younger age-groups By 1963 or 1964 many of the internationally assisted yaws campaigns will have passed into the surveillance phase During 1961, the World Health Organization started an appraisal of the results of the yaws campaigns and the methods used Special attention has been directed to the co-ordination of anti-yaws activities with those of other communicable disease control programmes and of the rural health services

Arterial Hypertension

ALTHOUGH there are, as yet, no effective means of preventing the occurrence of either arterial hypertension or ischæmic heart disease, much may be done in the individual case to delay or prevent the progress and complications of these diseases A report issued by the World Health Organization discusses the various preventive measures that can be applied (*Technical Report Series* No 231 *Arterial Hypertension and Ischæmic Heart Disease Preventive Aspects* Pp 28 Geneva World Health Organization, London H M S O, 1962 1 Swiss franc, 1*s* 9*d* , 0 30 dollars) It describes standard methods for determining blood pressure and classifies both arterial hypertension and ischæmic heart disease into their main clinical categories and stages, with the view of identifying those individuals likely to benefit from regular supervision and treatment A programme of research is suggested, and annexes appended to the report deal with criteria for the differential diagnosis of essential and renal hypertension and with methods for assessing renal function in hypertension

Cancer Research in Budapest

THE report of the Research Institute of Oncopathology, Budapest, for 1958–62 contains detailed accounts of the scientific work carried out at the Institute (Pp 24 Budapest Research Institute of Oncopathology, 1962) Among the main headlines under which the work of different sections is described are pathogenesis and morphogenesis, metastasis formation and how it is influenced, autolysis of tumour cells, chemotherapy, the lipid metabolism of tumours and clinico-pathology The report is published in English, and the Institute's address is Budapest, XII, Rath Gy, u 5, Hungary

Deprivation of Maternal Care

BOWLBY'S monograph, *Maternal Care and Mental Health,* was published by the World Health Organization in 1951, and was at once acclaimed as an unequalled contribution to this subject Its success is attested to by the frequency with which it has been reprinted and the number of languages into which it has been translated It has given wide currency to the term 'maternal deprivation' and has influenced the care given to children in institutions, residential nurseries and hospitals in many countries During the ten years that have elapsed since Bowlby's monograph was published, considerable research has been carried out into various aspects of maternal deprivation Bowlby's views have been subjected to much criticism, some of which is based on the often over-simplified, extreme or distorted interpretations of them prevalent in popular versions, but some of which is constructive and valuable The result has been that the problem of maternal deprivation can now be seen in a wider perspective than it was in 1951 A volume in the series *Public Health Papers* contains a group of papers reviewing the problem of maternal deprivation in this wider perspective (No 14 *Deprivation of Maternal Care a Reassessment of its Effects* Pp 165 Geneva World Health Organization, London H M S O, 1962 7 Swiss francs, 12*s* , 2 25 dollars) It contains contributions by psychiatrists and specialists in allied disciplines, and also by cultural anthropologists and a writer on social science The longest contribution is by a fellow-worker of Bowlby's, and as the latter has read this paper and agreed with it, it may be taken as representing his present views on maternal deprivation

Family Planning Association

THE remarkable progress of the Family Planning Association during the thirty-one years of its existence is emphasized in two notes in its annual report (Pp 26 Family Planning Association, 64 Sloane Street, London, S W 1, 1962) In its revised declaration on the Christian view of marriage and the family, the Methodist Church condemns careless and improvident begetting of children While recognizing that some Christians believe that the only legitimate means of conception control is abstinence from intercourse when a child is not desired, the Methodist Church believes that there are other permissible ways of preventing conception, provided that the means used are acceptable to both husband and wife and that, on the best evidence available, they do neither physical nor emotional harm The declaration goes on to say "When contraception is chosen as the means of family planning competent medical advice shall be sought, such as that provided by the Family Planning Association" Although during the past few years a number of encouraging statements on this subject have been made by responsible ecclesiastical bodies, the Methodist declaration is the first which has specifically mentioned the Family Planning Association The progress of the Association, as reflected by returns from its branches, is as follows

	1960	1961
No of clinics	340	366
No of sessions	20,733	22,246
Individual patients	212,324	284,163
No of visits or references	495,903	698,168
New patients	89,988	90,157
Pre-marital patients	14,120	16,452
Sub-fertility patients	1,567	1,836
Marital difficulty patients	1,329	1,465

The figures do not include the activities of the laboratories at the Association's Central Office Here, during the period under review, 2,132 sub-fertility patients were seen and more than 5,880 pregnancy diagnosis tests were carried out with specimens coming in from as far afield as Bahrein Island and the Persian Gulf In considering the figure of 16,452 patients, it is noteworthy that 380,000 women were married in England, Scotland and Wales during 1961 The number seeking advice is still very small

Planning the Future Metropolis

THE winter 1961 issue of *Daedalus*, the journal of the American Academy of Arts and Sciences, was devoted to "The Future Metropolis", including articles by R Vernon on the economics and finances of the large metropolis, A Fleisher on the influence of technology on urban forms, E C Banfield on the political implications of metropolitan growth, K W Deutsch on social communication and the metropolis, and J Dyckman on the changing uses of the city About a third of the *Proceedings of the American Philosophical Society* for June 29, 1962, is devoted to the allied theme of metropolitan planning Economic aspects of metropolitan planning are discussed by B Harris, transportation problems and their solution by R B Mitchell, the legal basis for reorganizing metropolitan areas in a free society by C Abrams, and urban form by G H Perkins

Research Careers in the Ministry of Defence, India

A BOOKLET issued by the Indian Ministry of Defence has the primary object of inviting graduates in technology and engineering, postgraduate research workers and other scientists and engineers, to consider the opportunities for taking up a research and development career in the Defence Research Laboratories/Establishments of the Research and Development Organization, as members of the Defence Science Service, India Research and development activities of the Organization cover a wide field and embrace subjects as different as, for example, explosives and psychology The researches are carried out either individually or by small teams in the Research and Development Laboratories/Establishments which are spread throughout India and have considerable resources The work is carried out in an atmosphere in which any enthusiastic person with a flair for research and inventive bent of mind would feel at ease The defence scientists get opportunities of giving lectures, attending conferences in India and abroad, participating in symposia, exchanging ideas through contact with scientists in universities and other establishments, and of becoming known in the scientific world generally. They are encouraged to publish papers and also to submit theses for postgraduate degrees on their research work when this is not of a secret nature, patents are taken out whenever permissible They may also be selected for attachment to establishments in India or abroad Copies of the booklet are obtainable from the Research and Development Organization, Ministry of Defence, "*G*" Block, Hastings Road, New Delhi-11

Analytical Methods for Fruit Juices

A VALUABLE compilation on *Analytical Methods for Fruit Juices* has recently been produced in Paris by the International Federation of the Producers of Fruit Juices It consists of methods of analysis acceptable to members from all countries affiliated to the Federation The project has been the responsibility of the Scientific and Technical Commission of the Federation, and the collaborative work has been organized by the Sub-Committee on Unification of Analytical Methods, of which Prof W Diemair of the University of Frankfurt is the chairman The brochure just published contains seven methods of analysis accompanied by drawings of all apparatus, graphs and tables necessary for the determination of specific gravity, alcohol, titratable acidity, sugar (before and after inversion), volatile acidity and total sulphur dioxide The methods are presented in French, German and English The complete compilation can be obtained, postage paid, for N F 15, from Fédération Internationale des Producteurs de jus de fruits, 16 rue de la Chaussée d'Antin, Paris (9°)

Excavation in New Zealand

ANY attempt at getting a relative chronology in New Zealand is always welcome, even when the various layers are of no great antiquity C D Smart and Roger C Green have recently been excavating a stratified dune site at Tairua, Coromandel, New Zealand (*Dominion Museum Records in Ethnology*, Vol 1, No 7 *A Stratified Dune Site at Tairua, Coromandel* By C D Smart and Roger C Green With a specialist report by J C Yaldwyn Pp 243–266 Wellington, N Z Dominion Museum, 1962) There is a specialist report on the fauna found, by John Yaldwyn The site is on the rocky islet of Paku at the mouth of the Tairua harbour There are no less than 9 layers, but only two are of archæological interest While there is no reason to think that any of the finds are earlier than the fourteenth century, the study of the so-called Archaic phase is much advanced as a result of this excavation The artefacts include drills, obsidian knives, scrapers, etc Among the bones, those of the moa have been identified

Australian Rock Carvings

IN Australia the archæologist has gone ahead of the quaternary geologist Much detailed study of the many rock carvings which occur has been made, but very little in the way of a relative and actual chronology has yet been attempted Among field workers the name of C P Mountford is well known In the July issue of *Man*, together with Robert Edwards, he describes a number of engravings and carvings allegedly representing marine animals from sites very remote from the sea It is suggested that they are of great antiquity, and date to a time when the sea was nearby If the identifications are correct it is now up to the geologist to say when the sea actually was nearby, or whether folk-memory must be invoked

Preserving Rural Wales

TESTAMENT to the work of so many devoted people in preserving the amenities of Wales, the combined annual reports for 1959–60 and 1960–61 of the Council for the Preservation of Rural Wales contain accounts of activities promoted to see that electricity transmissions are sited with discrimination, that town and country planning is carried out with a thought to the future, that historic buildings are not wantonly destroyed, that mineral undertakings are not only concerned with costs, that the beauty of the coasts are preserved and that adequate precautions are taken to prevent the spread of litter (Pp 93+2 plates Machynlleth, Montgomeryshire Council for the Preservation of Rural Wales, 1962) The reports also contain accounts of the best-kept village competitions A sad feature of the reports is the record of the small number of members in Monmouthshire

The Weizmann Institute of Science

THE report of scientific activities of the Weizmann Institute of Science for the two years 1960–61 gives short accounts of the work in progress in the various departments (Pp 151 Rehovoth The Weizmann Institute of Science, 1962) These include Applied Mathematics, Biophysics, Nuclear Magnetic Resonance, Nuclear Physics, Organic Chemistry, Plant Genetics, Polymer Research, X-Ray Crystallography, and the new Departments of Virology and Genetics, Cell Biology, Biodynamics and Carbohydrate Metabolism formed out of the Department of Experimental Biology during the period, as well as of the sections of Biochemistry, Electronics, Infra-red Spectroscopy, Isotope Research and Photochemistry and Spectroscopy To each of these is attached a list of publications, and there are also reports from the Graduate School in the Natural Sciences and the Library with a list of scientific staff of the Institute Among the numerous subjects under investigation it must suffice to mention the work on the biological synthesis of peptides and proteins, the catalysis of photophosphorylation by chloroplasts, on bacterial ribosomes, the physical chemistry and synthesis of ribonucleic acid, the synthesis and properties of low molecular weight peptides and polyamino-acids, polypeptidyl proteins, viruses and bacteria, synthetic polypeptide antigens, the structure and biological activity of proteins, biochemical aspects of urethane carcinogenesis, mechanism of epileptic behaviour, the chemistry of sphingolipids, effect of gibberellins on morphogenesis of *Cucumis sativis* and the properties of polyelectrolyte-salt solutions.

Organizing Scientific Research in Poland

The *Review of the Polish Academy of Sciences* for April–June 1962 contains an article by J Malecki describing the purpose and objects of the long-term plan for the Development of Science in Poland, the way work on the plan is being organized, and the measures being taken to develop a supply of the necessary scientific personnel and to organize the scientific research involved The plan envisages an increasing use of 'directed' research during the next twenty years, but although in this context the word 'directed' is used in much the sense in which 'applied' is used in Britain, it appears to imply a certain amount of direction at least to the extent of ensuring effective use of expensive equipment and the avoidance of duplication of effort, as is done by the grants from the Department of Scientific and Industrial Research Particular attention is also given to the encouragement of interdisciplinary effort It is proposed to rely on relatively small but highly specialized teams The same issue also includes an article by W Nowacki "Links between Science and Life" This discusses the general principles of scientific policy and the contribution of the Polish Academy of Sciences in particular, including the organization of fundamental and applied research and the problem of encouraging the application of results

Gordon Dean Memorial Fellowship Fund for Nuclear Science

A MEMORIAL fellowship fund has been created to honour the late Gordon Dean, former chairman of the U S Atomic Energy Commission and co-founder of the Nuclear Science and Engineering Corporation Former President Harry S Truman has been elected honorary chairman of the Gordon Dean Memorial Fund, which will grant scholarships and fellowships for study and research in nuclear science Until his untimely death in 1958 in a plane crash, Mr Dean served as chairman of the board at Nuclear Science and Engineering, which he founded with Mr Brightsen in 1954 At the time of his death, he was also senior vice-president of General Dynamics Corporation and an adviser on atomic energy to the investment banking firm of Lehman Brothers Further information can be obtained from the Nuclear Science and Engineering Corporation, P O Box 10901, Pittsburgh 36, Pennsylvania

The Night Sky in October

FULL moon occurs on Oct 13d 12h 33m U T and new moon on Oct 28d 13h 05m The following conjunctions with the Moon take place Oct 2d 09h, Venus 11° S, Oct 8d 11h, Saturn 0 9° S, Oct 10d 11h, Jupiter 1° N, Oct 21d 01h, Mars 1° N In addition to these conjunctions with the Moon, Mercury is in conjunction with Spica on Oct 30d 21h, Mercury being 4° N Mercury is a morning star, visible low in the south-east before sunrise, and may be favourably observed during the later part of the month when it rises nearly two hours before the Sun Venus is too close to the Sun for easy observation Mars rises at 22h 55m, 22h 40m and 22h 25m on Oct 1, 15 and 31, respectively It is at a distance of 129 million miles on October 15, and its stellar magnitude is +0 9 Jupiter sets at 2h 50m, 1h 50m and 0h 50m at the beginning, middle and end of the month, respectively It is in Aquarius, its stellar magnitude is −2 3 and its distance from the Earth in the middle of the month is 396 million miles Saturn is in Capricornus, setting at 0h 00m, 23h 05m and 22h 05m on Oct 1, 15 and 31, respectively Its stellar magnitude is +0 7 and its distance from the Earth on October 15 is 898 million miles Occultations of stars brighter than magnitude 6 are as follows, observations being made at Greenwich Oct 9d 18h 09 4m, δ Cap (*R*), Oct 14d 22h 12 5m, μ Cet (*D*), Oct 14d 22h 53 6m, μ Cet (*R*), Oct 21d 00h 26 6m, θ Cnc (*R*) *D* and *R* refer to disappearance and reappearance, respectively The Orionid meteors are active during October 15–25 but conditions for observation are unfavourable

Announcements

OPEN DAYS will be held at the National Chemical Laboratory, Teddington, on September 26 and 27 Further information can be obtained from the Chief Press Officer, Department of Scientific and Industrial Research, State House, High Holborn, London, W C 1

THE second annual meeting of the American Society for Cell Biology will be held at the Jack Tar Hotel, San Francisco, during November 5–7 Further information can be obtained from Dr M Alfert, Department of Zoology, University of California, Berkeley 4, California

A SYMPOSIUM on "Fungi and their Metabolites" is to be held under the auspices of the Plant Phenolics Group and the British Mycological Society in the School of Pharmacy, London, W C 1, on October 1 and 2 Further information can be obtained from Dr J G Manners, Department of Botany, The University, Southampton

THE third Rapkine Memorial Lecture of the Institute of Biology will be delivered by Prof F Morel, of the French Centre for Nuclear Studies, Saclay, on October 8, at the French Institute, Queensberry Place, London, S W 7 Further information can be obtained from the General Secretary, Institute of Biology, 41 Queen's Gate, London, S W 7

THE twelfth Dalton Lecture of the Royal Institute of Chemistry will be delivered by Sir Lawrence Bragg on October 24 in the Town Hall, Manchester The title of Sir Lawrence's lecture will be "Living Molecules" Further information can be obtained from Mr H H Armstrong, Science Department, College for Further Education, Wellington Road South, Stockport

DR J H VAN DER WAALS, Koninklijke/Shell Laboratorium, Amsterdam, will deliver the following Bourke Lectures of the Faraday Society "Study of the Phosphorescent State of Organic Molecules by Electron Resonance" (University of Nottingham on October 23 and University of Sheffield on October 26), "Clathrates as Elementary Solutions" (University of Oxford on October 30) Further information can be obtained from the Faraday Society, 6 Gray's Inn Square, London, W C 1

ERRATUM In the communication entitled "Stomatal Sensitivity to Low-Intensity Illumination in *Xanthium pennsylvanicum*", by Dr T A Mansfield, which appeared on p 514 of the August 4 issue of *Nature*, the second sentence of the first paragraph should read, "The rhythm was shown 10 lux given instead of darkness was sufficient to delay its progress"

SCIENTIFIC AND TECHNICAL RESEARCH IN ARGENTINA

THE annual report (February 1, 1961—January 31, 1962) of the National Council for Scientific and Technical Research of the Argentine Republic has recently been published

One of the main activities of the Council continues to be the award of fellowships, with the object of training for research In the period covered by the report, 146 fellowships were granted, 53 of them to carry out research projects in scientific institutions abroad and 93 for the same purpose in Argentina, apart from numerous extensions of fellowships granted the previous year The total amount of fellowships awarded by the Council during the four years of its existence is 571, of which 319 were awarded for research carried out in Argentina and 252 abroad Reports received from universities and research centres of the United States, Great Britain, France and other countries which have received Council Fellows emphasize the high standard and achievements of these men

During the period covered by the report, the Council has intensified its aid to different research projects by means of grants The total amount granted exceeded 80 million Argentine pesos

Grants are awarded primarily for the purchase of scientific equipment and to finance research projects In some cases they have been awarded for the building of new laboratories, for example, the Institute of Computing, Faculty of Exact and Natural Sciences, University of Buenos Aires, the Radiocarbon Dating Laboratory for Archæological and Geological Research, being installed at La Plata University as a joint project of the Council and the former, the Laboratory of Neurophysiology, already operating in the Institute of Experimental Biology and Medicine, located in Buenos Aires The Council has also contributed towards equipping and staffing the Town Planning Institute of the Universidad del Litoral, in Rosario In all such cases and other similar ones, the Council, while awarding the funds for the creation of new research centres, resolved that they should operate under the ægis of other institutions

Lately, however, the Council has decided to create some research centres under its own jurisdiction This is considered a fitting way to establish new research facilities for Argentine scientists, and will permit a better co-ordination of efforts in certain fields, apart from filling some scientific gaps The aim is to organize a few model institutes, and to this end numerous projects are actually under investigation by the Council

In another section of the report it is mentioned that during 1961 the 'Research Scientist's Career' was put into operation This programme has been established by the Council with the object of fostering full-time dedication to original research, offering investigators better conditions than heretofore from the point of view of financial security and advancement, while tending to making research an attractive proposition for young graduates with a scientific vocation Registration was opened by mid-1960, and applications filed up to the end of March 1962 totalled 494 of which 276 applicants were admitted. Of these, about 200 scientists have already complied with the necessary formalities and are actively engaged in research work within the scheme Applications continue to be filed in considerable numbers, revealing a healthy interest in scientific research among young university graduates

The Council has continued with its programme of inducing qualified Argentine research scientists settled abroad to return to the country The report points out that it has been possible to retrieve Argentine men of science who held important positions in well-known foreign institutions by using funds earmarked for repatriation purposes Increasingly favourable conditions for scientific research which have been created in the country during the past few years have, of course, played a predominant part

During 1961, the Council considerably stepped up the programme aiming at the improvement of teaching scientific subjects at high-school level With this object in mind, the Council has made available to secondary school science teachers the opportunity of improving their knowledge by attending refresher courses in the country and also abroad A physics summer course for secondary school teachers, selected from all over the country, was held at the beginning of 1961 Four more courses were organized for the summer of 1962, in mathematics, physics, chemistry and biology A total of 123 high-school teachers attended these courses

During 1961, two Argentine high-school teachers (mathematics and physics) attended the Oak Ridge Institute of Nuclear Studies, in Tennessee, while six others attended summer school courses organized by the U S National Science Foundation It has also been possible to send some Argentine high-school teachers to refresher courses organized by the Pan-American Union in other Latin-American countries

Simultaneously, efforts are being made by the Council to bring up to date science teaching at secondary school level in Argentina and also to foster the interest of high-school graduates in scientific careers

Mention is made of the different services rendered to research scientists by the Council, such as making available scientific information by means of microfilm, photostats, publications, etc

Another chapter of the report refers to international scientific relations and contacts established by the Council It is stated that the Council is the national member of the International Council of Scientific Unions (ICSU), the International Council for Medical Sciences (CIOMS), the International Committee on Space Research (COSPAR) and the International Federation of Documentation (FID)

Another aspect of contacts with scientific circles abroad are the invitations extended by the Council to foreign scientists of international standing in order to lecture in Argentina or to act in an advisory capacity on research projects Argentine delegates are also sent by the Council to many international scientific meetings It is pointed out that the Council finances the attendance of Argentine scientists at international meetings when certain conditions are fulfilled by the candidates, such as authorship of a paper on original research work which has gained acceptance by the organizing committee of the meeting Due emphasis is given to the generous aid received from the Ford and Rockefeller Foundations of the United States which has enabled the Council to extend considerably its fellowship programme and has helped to finance some of the activities already mentioned

A brief analysis of the Council's budget for the fiscal year which ended on October 31, 1961, shows that the amount budgeted was Argentine pesos 211,386,009,90 (about £1 million at the then prevailing rate of exchange) Expenditures for the same period did not amount to the total budgeted, and it is noteworthy that administrative expenses amounted to only 8 per cent of the total expenditure

During 1961, the Council resolved to buy a building in order to have more adequate premises The future address is Rivadavia 1917, Buenos Aires, Argentina, where the Council expects to move before the end of the year, once the necessary alterations have been completed

In the final part of the report, overall aspects of the Council's task are given consideration They can be summed up by the considerable increase of young scientists adequately trained for research, the larger volume of research work undertaken in Argentina with the aid of Council funds granted to institutions and scientists, the establishing of new research teams and research centres and the higher level attained by research work in different fields It is emphasized that the activity of the Council, combined with that of some other institutions carried out along similar lines in the past few years, has established a most favourable environment for original and creative scientific research by fostering the general interest in scientific activity and obtaining increased aid for its continuation from official quarters as well as from the general public

CYTOCHEMICAL PROGRESS IN ELECTRON MICROSCOPY

THE symposium on "Cytochemical Progress in Electron Microscopy", which was held by the Royal Microscopical Society in Oxford during July 2–4, was a success both in the size of the attendance and the interest of the topics The majority of those attending were British, but several papers were submitted from France and others from Belgium, the United States, Holland and Sweden

The information presented fell into four categories (1) Effects of different fixatives, embedding media and electron-absorbing 'stains' on morphological detail (2) Sub-microscopic localization of enzymes utilizing electron-absorbing cytochemical reaction products (3) The effects on morphological detail of extraction by chemical or enzymatic reagents (4) Autoradiography at electron-microscope magnifications It is a pity that the symposium was not organized to present consecutively the papers covered by these or similar headings As it was, the fragmentation of discussion of any one topic prevented the important points resulting from it from being clearly presented to the non-specialist in the audience

Under the first of the headings which I have chosen here, Dr W Bernhard and Dr Elizabeth Leduc (Villejuif, France) presented beautiful pictures of the striking difference in appearance produced in tissues embedded in water-soluble glycol-methacrylate, compared with those embedded in media soluble only in organic solvents These results were enlarged on by Dr V Marinozzi (Villejuif), who presented much useful information on differences produced by fixation in various solutions and embedding in different non-water-soluble media Much technical information will be available as a result of the investigations of Dr J Sikorski (Leeds) on keratinous cells, of Dr J R Casely-Smith (Villejuif) on fixation and staining of lipids, and of Dr E H Mercer (London) and Drs W Th Daems and J P Persijn (Leyden, Holland) on 'stains' for electron microscopy The papers of Drs E L Benedetti and B Bertolini (Amsterdam), on the use of phosphotungstic acid as a stain for the plasma membrane, and Dr R L Tapp (Cambridge), on the fine structure of desmosomes after a variety of techniques, illustrated the necessity of studying cell structure after using a variety of methods of preparation before attempting to interpret the functional significance of the details detected

The value of using light-microscopy to investigate material and the changes which occur in it during preparation for electron microscopy was underlined by the papers of Prof N A Barnicott (London) and Dr H E Huxley (Cambridge) on their investigations of chromosomes and Dr H G Davies (London) on his experiments with erythrocyte nuclei It is to be hoped that the structureless nature of the chromosomes which was so beautifully displayed may be due to fixation artefacts as was suggested by the information provided by Dr B M Richards (London) in the discussion

The most striking results in cytochemical investigations at the electron-microscope level have been those of the American and German workers using enzyme reaction products containing heavy metals In the absence of these original contributors Dr A G E Pearse (London) gave a lucid account of the possibilities of this approach He pointed out the incompatibility of good osmium fixation and the preservation of some enzymes, but also indicated that a method giving a bad picture at the light-microscope level might give a good one in the electron microscope He also warned that much shorter incubation of tissues in substrates would probably be required if good electron micrographs devoid of diffusion of reaction product were to be obtained Drs S J Holt and Marian Hicks (London) illustrated many of these points with their paper on the localization of acid phosphatase in lysosome-like particles Drs G de Thé, A B Novikoff and J W Beard (North Carolina) showed among other things that virus particles on entering and leaving a cell not only acquired a covering of part of the cellular membranes but also the adenosine triphosphatase activity associated with these membranes It is this sort of result which makes the detailed work of cytochemistry at the electron-microscope level worth while Dr B Boothroyd (Liverpool), in his paper on the effect of electron irradiation on glycogen, showed pictures of this polysaccharide stained by the periodic acid–Schiff technique, which illustrates that deposition of sufficient organic stain at a locus may sufficiently raise its electron-absorbing properties as to give good contrast in the electron microscope This has already been found to be the case at ultra-soft X-ray wave-lengths, and some preliminary work suggests that heavy metals need not be incorporated into enzyme reaction products in order to make them absorb electrons sufficiently

The use of extraction methods, and biochemical and cytological control of the extraction process, were well illustrated by Drs S and M Nass (Stockholm), who postulated that a deoxyribonucleic acid-like material was present in mitochondria Drs R R Dourmashkin, R M Dougherty and R J C Harris (London) presented their superb pictures of the pits or holes in virus and cell membranes after these had been extracted with saponin and digitonin

The introductory review by Dr S R Pelc (London) on the theory of autoradiography presented the background to the limitations of the use of conventional photographic emulsions in studying isotope localization with the electron microscope Drs G A Meek (Oxford) and M J Moses (North Carolina) presented excellent pictures of the localization of ^{3}H-thymidine in HeLa cells Dr P Granboulan (Villejuif) discussed the resolving power and sensitivity of some new emulsions and showed autoradiographs with extremely small grains (0 1μ) Dr H Firket (Liège), working in conjunction with Dr Granboulan, showed the result of the use of these emulsions in studying the incorporation of ^{3}H-uridine in cells A lively discussion followed all these papers and the questions of resolution (spatial relation between developed grain and emitting particle) and the probability of biological significance of a few developed grains overlying cellular structures were widely debated It appears that progress in this branch of electron microscope cytochemistry will depend on the exploitation of photosensitive layers other than silver halide–gelatin emulsions and the use of less-conventional methods of development These methods have been described in the literature of photographic processes

Presentation of the use of the electron microscope for studying the localization of antigens in cells by staining them with antibody conjugated to ferritin was made by Miss Jane Baxandall and Drs P Perlmann and B A Afzelius (Stockholm) and by Dr Margaret Mott (Edinburgh) These methods appear to permit localization of substance on the surface of the cells, but the contrast of the conjugate is so low as to give a rather unconvincing picture This is another case where 'chromaticity' in the electron microscope would be useful in identifying the iron component of the conjugate

The contrast of the modern approach used by the contributors and the near-medieval surroundings in which they were lodged during the conference was even greater than that between the excellent new lecture theatre in which the scientific sessions were held and the fabric of the University Museum which contains it It is to be hoped that the Royal Microscopical Society will before long present another symposium of such topical interest

The communications will be published in detail in the Society's *Journal* by the end of this year A J H

RADIO RESEARCH 1961

IN the previous report of the Radio Research Board, it was noted that Mr J A Ratcliffe took over his duties as director of the Radio Research Station on October 1, 1961 (see *Nature*, 185, 354, 1960 191, 1255, 1961) The report for 1961 has now become available*

This report describes the action that has been taken to implement earlier decisions to devote half the effort available to the Radio Research Station to a programme of space research and by this is meant the use of sounding rockets and satellites to carry out fundamental investigations of the upper atmosphere and ionosphere, and of the factors which determine the behaviour of these media for transmitting radio waves

For many years past the work of the Radio Research Station has included detailed measurements of the properties of the ionosphere and the application of the results to the study of the propagation of high-frequency radio waves over long distances Charts are now available giving detailed characteristics of the *F* region of the ionosphere for the conditions of maximum and minimum solar activity By sensible extrapolation, these can be used to calculate the transmission characteristics required for various point-to-point communication services Experiments are in hand to check these calculations by a pulse transmission technique between Slough and New Delhi—a distance of some 7,000 km

In parallel with this work, which is based on investigations of the ionosphere from below, the facilities provided by radio transmissions from rockets and satellites are now being used to explore the ionosphere above the height of peak ionization Two methods are in use for observing the waves transmitted downwards from an artificial satellite at a height of several hundred kilometres In the first, measurements are made at Slough and Singapore of the Faraday rotation of the plane of polarization of a wave transmitted through the ionosphere The second method in use at Slough records the Doppler shift on two harmonically related frequencies due to the motion of the satellite The result is used to calculate the total electron content in the ionosphere

This work makes use of the facilities now availabe at Winkfield, near Slough, for the tracking of American satellites and the recording of the telemetry signals received from them The same equipments, together with the corresponding installations at Singapore and Port Stanley, are being used for co-operating in the British experiments now in progress with the American satellite *S*-51, which was planned for investigations organized by the British National Committee on Space Research Preparations are also well advanced to enable all three of the above stations to participate in the reception of the telemetry signals from the United States and Canadian 'topside sounding' satellites The purpose of these satellites, expected to be launched in the near future, is to study the characteristics of the upper part of the ionosphere by radio-wave sounding from heights well above that of the peak ionization

---

* Department of Scientific and Industrial Research Radio Research 1961 The Report of the Radio Research Board and the Report of the Director of Radio Research Pp iv+27+4 plates. (London H M S O , 1962) 3s net

Investigations of the characteristics of the troposphere continued to be conducted by staff of the Radio Research Station by several different methods The micro-wave radio refractometer carried in an aircraft, as described in previous reports, has been used to record the gradient of refractive index at various heights and in several cases these have been correlated with the existence of layer-type echoes observed by vertical-sounding radar technique The process of the scattering of radio waves by discrete layers or other types of discontinuity in the troposphere has been studied by measuring the variations in direction of transmission of a narrow beam of waves To some extent, the results have been related to the prevailing meteorological conditions, taking advantage of information, when available, obtained from radio-sonde ascents

A programme of international intercomparison of reference standards for measuring power at microwave frequencies has been in progress for several years A wire bolometer transfer standard for use at a frequency of about 9 Gc/s, which had been calibrated by microcalorimeter reference standards in the United States and in Japan, was checked against a film bolometer standard developed at the Radio Research Station The results were in agreement with the American and Japanese reference standards to within ± 0 9 per cent At a lower frequency of 300 Mc/s, a coaxial transfer standard submitted by the National Bureau of Standards, Boulder Laboratories, was compared with two instruments at Slough a coaxial thermionic diode and a thermistor milliwattmeter The measurements made in the United States and United Kingdom agreed to within 0 3 per cent, which is well within the limits of error assigned to any one of the reference standards The various techniques now available in the United Kingdom make it possible to carry out measurements of power above a few milliwatts at frequencies up to 30 Gc/s Power measurement at higher frequencies probably depends on the development of new techniques

As in the case of previous reports, appendixes give details of the Committees of the Radio Research Board, the staff of the Radio Research Station and the papers published by them during 1961.

SATELLITE METEOROLOGY

SINCE the first observations commenced to be received from *Tiros* 1 there has been much speculation concerning the optimum utilization of meteorological satellites in meteorological operations and research In particular, it is reasonable to inquire whether the enthusiasm and novelty which these spectacular technical advancements have aroused will gradually fade away with the realization that, however spectacular they may be, their real value is limited, or whether the observations will represent a true potential for meteorological operations and research

It has always been appreciated that the main practical value of the observations lies in the use which can be made of cloud picture mosaics in regions where the supply of weather reports from the normal station network is inadequate This is especially so over the huge extent of the oceans of the globe, much of which is only sparsely threaded with ships' trading routes, assisted at a few strategic places by ocean weather stations The identification of incipient, or even fully developed, tropical cyclones before they have been picked up by the conventional observational network represents an outstanding and much publicized example of the great value which cloud observations from satellites can be to national meteorological services charged with giving timely preventative warnings to communities likely to be affected by these devastating storms But such occurrences are relatively rare in the spectrum of meteorological events, and it is hoped that more lasting and regular returns will be received from these expensive observations

There are many less-obvious uses of observations from meteorological satellites The photographs themselves can reveal the distribution of snow and ice-fields in addition to cloud cover Photographs of snow-covered land masses can, for example, help to provide information about water resources At night, when clouds are not properly visible, an approximate distribution of the cloud pattern may be obtained from infra-red radiation measurements Such radiation suffers little absorption during its passage through the atmosphere and enables an estimate to be made of the temperature of the radiating surface Clouds are thus revealed as cold areas against the warmer background of the Earth's surface The temperature pattern of the upper cloud surface may yield an index of the contours of that surface

Future developments may enable measurements to be made in the centimetre wave-length band which would identify precipitation areas and freezing-levels by radar techniques It should also be possible for observations of lightning to be made, either by visible flashes or by sferics discharges Finally, it has been suggested that the satellites might be used for global communications to relay pressure, temperature and wind data made by automatic weather stations in oceans and remote land areas

The United Nations General Assembly has shown an awareness of the international aspects of the question in passing a resolution dealing with International Co-operation in the Peaceful Uses of Outer Space A section of this resolution of December 1961 includes a request that the World Meteorological Organization should report to its member Governments on the appropriate organizational and financial arrangements (1) to provide a greater knowledge of the basic physical forces affecting climate and the possibility of large-scale weather modifications, (2) to help members to make the utmost use of existing weather forecasting possibilities

The report has now been prepared*, it lists several basic requirements to translate the potential of weather satellites into a working scheme

There is first a need for an internationally coordinated plan to achieve agreed decisions concerning satellite orbits, types of observations to be made collection and dissemination of data and standardization of accuracies The plan should provide for research on the use of the data received The most important recommendation in the report is no doubt the call for a 'world weather watch', a global meteorological observing and prediction system designed to avoid duplication of effort in the preparation of analysed charts and forecasts, yet providing all meteorological services with the basic data needed to carry out their responsibilities The report also proposes that the scope and quality of both conventional and satellite observations should be improved and emphasizes that the latter supplement but do not supplant the former Optimum results can be achieved by means of a combination of the wide scanning ability of the satellites with the capabilities of the usual vertical sounding instruments Improvements should also be made to the communication facilities to permit the rapid transmission of a greatly increased volume of meteorological traffic throughout the world The hope is expressed that the satellites themselves may serve as communication systems for this purpose

---

* *WMO Bulletin*, 11, No 3, July 196

The evaluation of the optimum utilization of meteorological satellites is an important issue that must be faced The United Nations and its specialized agency, the World Meteorological Organization, have taken a big step forward The working group which has been established to formulate an atmospheric sciences programme will keep the matter under active review until the World Meteorological Organization Congress constitutes an advisory committee at its fourth session in April 1963 There is a long road to tread before the full potential of meteorological satellites will come to fruition A H GORDON

FILARIASIS

DURING the past few years, filariasis control has progressed to the point where it has become possible to look forward to the introduction of eradication campaigns like that organized by the World Health Organization for malaria In contrast to the malaria programmes, however, the first line of attack would have to be mass chemotherapy, mainly because of the long life of the parasite in the human body To keep transmission at a low enough level to ensure eradication, chemotherapy will have to be backed up by adequate vector control This may not prove easy, since the culicine mosquitoes, the main vectors of filariasis, rapidly acquire resistance to the commonly used insecticides and since the habitats of some of the mosquitoes make it difficult to attack them by conventional methods

The World Health Organization Expert Committee on Filariasis has reviewed recent advances in the epidemiology of *Wuchereria* and *Brugia* infections and directed attention to the many problems on which research is still needed* It is important to improve methods of identifying developing forms of filariæ in mosquitoes, so that carriers of animal filariæ should not be mistaken for vectors of the human infection Expert taxonomic, ecological and other studies are needed to establish the strains with the highest infective potential and the most effective means of destroying them Rapid urbanization has enabled *Culex fatigans* to breed apace in some areas with only primitive sanitation, and the situation has been made worse where insecticide spraying campaigns for malaria eradication have eliminated competitors of this mosquito The Committee recommends that, wherever possible, *Culex fatigans* should be attacked by improvements in sanitation aimed at suppressing man-made breeding sites

Diethylcarbamazine appears to be still the most satisfactory drug available for mass chemotherapy, but a number of new compounds containing arsenic or antimony are at present under trial Further research is needed to establish the best dosage schedule for diethylcarbamazine—one that, in order to ensure a high acceptability, combines effectiveness with ease of administration and relative freedom from side-effects

Among the other subjects suggested for research, the Committee advocates studies on transmission and on the life-cycle of the parasite in relation to clinical manifestations, serological and immunological studies on filariasis, and an investigation of the effect of malaria eradication activities on the local epidemiology of filariasis

INHERITANCE IN BACTERIA

AMONG the wide variety of research activities described in the report of the Governing Body of the Lister Institute of Preventive Medicine for 1962*, that of the investigations of the Guiness–Lister Unit into inheritance in bacteria is of particular interest. The Unit continued its investigation of inheritance in bacteria of the *Salmonella* (food poisoning and enteric fever) groups, using two different kinds of fertility factor to induce conjugation the colicine factors, which determine the production of antibiotics called colicines, and the *F* factor and some variants of it, transferred from *Escherichia coli*

S Smith continued to map the chromosome of *Salmonella typhimurium*, obtaining conjugation (and hybridization) by the use of colicine factors *col I* and *col EI* Additional hereditary characters were introduced into the strains used, by the isolation of mutants unable to synthesize particular amino-acids, to ferment particular sugars or to produce the fraction of the polysaccharide component of the O antigen factor 5 Many of these mutants were obtained by treating bacteria with the mutagen ethyl methane sulphonate The genes regulating all the characters concerned were mapped in the single closed-loop linkage map already tentatively established Dr B A D Stocker, E Subbaiah, and E. Dubnau, using the same system, investigated the segregation of additional characters resulting from mutation in the laboratory or pre-existing in strains isolated from natural sources

---

* The Lister Institute of Preventive Medicine Report of the Governing Body 1962 Pp 29 (London The Lister Institute of Preventive Medicine, 1962)

From analogy with the situation in mating of *Escherichia coli* resulting from activity of the fertility factor *F*, it was suspected that, in conjugation of *Salmonella* induced by colicine factors, the partner carrying the colicine factor acts as a 'male' and injects a part or perhaps the whole of its chromosome into the cytoplasm of the other, 'female', partner Some data on frequency of various recombinant classes cast doubt on this idea, and suggested that perhaps the partner which was lacking the colicine factors sometimes acted as 'male' S Smith, in a further investigation of crosses in which a reversal of sexual roles was suspected, has now shown that if in such a cross the partner carrying the colicine factors is resistant to streptomycin and the other partner sensitive, exposure to streptomycin prevents the appearance of nearly all the streptomycin-resistant recombinants which develop in the absence of the antibiotic This is the result expected if only the colicogenic partner can inject its chromosome into its partner, for sensitive 'female' bacteria which had received a chromosome fragment from the streptomycin-resistant colicinogenic partner would be killed by the antibiotic, even when the injected chromosome fragment carried the gene for resistance to streptomycin, because of the streptomycin-sensitivity of their own cytoplasm

Subbaiah and Stocker established that two genes, regulating, respectively, ability to ferment rhamnose and ability to produce the filamentous bacterial appendages, called fimbriæ, are well separated in the chromosome and functionally independent, despite the almost complete correlation of the two characters in 'wild' strains of *Salmonella typhimurium* Now that the chromosome of *Salmonella typhimurium* has been reasonably well mapped, new investigations of the genetics of virulence in this species have been begun by Subbaiah As a start he has isolated a series of 'rough' mutants, in strain *LT*2, as the 'rough' character entails loss of virulence

GROWTH OF A CLONED STRAIN OF HAMSTER KIDNEY CELLS IN SUSPENDED CULTURES AND THEIR SUSCEPTIBILITY TO THE VIRUS OF FOOT-AND-MOUTH DISEASE

By P. B CAPSTICK, R C TELLING, W. G. CHAPMAN and DOREEN L. STEWART

Research Institute (Animal Virus Diseases), Pirbright

MACPHERSON and Stoker[1] have described the origin of the baby hamster kidney cell strain 21 (*BHK 21*), and Mowat and Chapman[2] the susceptibility of the strain to the virus of foot-and-mouth disease (*FMD*) in monolayer cultures All experiments so far reported with this cell strain have utilized cells grown in monolayer cultures The advantages of suspended cell culture techniques are obvious if the cell is to be used for large-scale vaccine production or even for extensive laboratory use in plaque assay systems The experiments described here demonstrate the growth of a cloned strain of these cells (clone 13) in suspended cell culture

Culture of cells in suspension was carried out in cylindrical 'Pyrex' glass vessels, 3 in in diameter, 10 in in height, with two glass entry ports in the top end The volume of culture used was 200 ml, which occupied about one-third of the vessels The cultures were stirred by central 'Teflon'-coated bar magnets rotated at 335 r p m by mechanically propelled external magnets The vessels were held in a 37° C copper water bath They were sealed with glass stoppers after seeding and no aeration was attempted Slight gas exchange with the atmosphere occurred when the cultures were sampled

The medium consisted of Eagle's basal medium modified to contain twice the normal concentration of amino-acids and vitamins with 10 per cent Seitz-filtered bovine serum and 10 per cent tryptose phosphate broth Antibiotics were incorporated to final concentrations per ml of 100 units penicillin and streptomycin, 25 units mycostatin, and 70 units neomycin

BHK 21 clone 13 cells which had had 110 monolayer transfers were suspended in the foregoing medium and added to the vessels, the contents of which were collected every 2 days or when the cell concentration in the vessels ceased to increase During the first 21 days in culture, growth was irregular with considerable clumping of cells and growth on the sides of the vessels This was counteracted by collecting the cells every 24 h and resuspending them in 'Versene'–trypsin (0 01 per cent) mixture in the vessels for 1 h The 'Versene'–trypsin was then removed and fresh medium substituted After this initial period, regular growth occurred and we were able to collect cells from the vessels every 48 h with a constant cell yield of 2 to 3 6 × $10^{8\ 0}$ cells per vessel Cell clumping was still a problem although there was little growth on the sides of vessels that had been in use for six days or more Better assessments of the number of cells in a vessel were obtained by collecting the contents and subjecting both cells and vessel to the 'Versene'–trypsin treatment described above

The results of a typical growth-cycle are shown in Fig 1, from which it can be seen that from a seed of 3 5 × $10^{5\ 0}$ cells per ml a final concentration of 1·65 × $10^{6\ 0}$ per ml was achieved in 40 h This figure also demonstrates that the growth-curve was linear in character, and this is presumptive evidence that a rate-limiting factor or factors was operating Further investigations on the nature of these limiting factors is being carried out

The work of Hayflick and Moorhead[3] on human diploid cell strains suggests that, to achieve successful growth in suspended culture, a diploid cell strain must change its chromosome karyotype from diploid to heteroploid and that a change may occur in the range of viruses to which the cell is susceptible We have not yet observed these changes with *BHK 21*

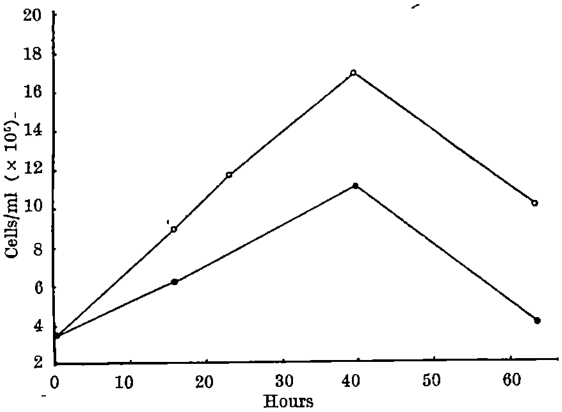

Fig 1 Growth of *BHK 21* clone 13 cells in suspension ●, Mean cell counts from replicate vessels before 'Versene'/trypsin action, ○, mean cell counts from replicate vessels after 'Versene'/trypsin action

clone 13 cells in suspended culture Table 1 shows the chromosome analyses of cells grown in monolayers and of the same cells after a further 66 days growth in suspended culture

Table 1 CHROMOSOME KARYOTYPE AND CELL SIZE OF *BHK 21* CLONE 13 CELLS GROWN IN MONOLAYERS AND AFTER A FURTHER 66 DAYS GROWTH IN SUSPENDED CULTURE

Cell passage history	Nuclei of diploid karyotype (per cent)	Nuclei of heteroploid karyotype (per cent)	Total mitotic nuclei determined	Modal cell size
110 monolayer transfers	93 1	6 9	350	13μ
110 monolayer transfers plus 66 days in suspended culture	91 8	8 2	777	13μ

Comparisons of *FMD* virus titres assayed in mice and on monolayers produced from suspended cells and monolayer-passaged cells are shown in Table 2 in which it can be seen that cell sensitivity has altered for some strains of *FMD* virus, although plaques of the same size were formed on both types of monolayers This change may be due to the fact that we have not yet determined the best method for using suspended cells in assay systems At the moment, these cells are being used under conditions which were found to give maximum sensitivity with cells produced in monolayers We have noted, however, that infection of roller tube monolayers prepared from suspended cells always results in the destruction of all the cells in the monolayer Thus, while cell sensitivity may be reduced, the cells appear to remain susceptible to higher concentrations of virus and are probably suitable for vaccine production Further work is in progress on the yields of virus per cell

Table 2 TITRATION OF FOUR STRAINS OF *FMD* VIRUS IN MICE AND CULTURES PRODUCED FROM MONOLAYER CELLS AND SUSPENDED CELLS

† Titre in tissue culture ID_{50} per ml

‡ Titre in mouse LD_{50} per ml

Cells propagated in the small vessels for 37 days have been transferred to a 5-l bacterial culture vessel[4] from which the baffles were removed From initial concentrations of about $3 \times 10^{5\ 0}$ cells per ml, maximum concentrations of about $1\ 5 \times 10^{6\ 0}$ cells per ml have been obtained in culture volumes of 2 5 and 4 1 with stirrer speeds of 400 and 480 r p m, respectively

The vessel is fitted with *p*H electrodes, and this allowed continuous monitoring of the *p*H of the culture A degree of aeration was achieved by continuously passing a mixture of air and carbon dioxide, at an arbitrarily selected flow-rate of 400 c c /min, across the top of the stirred culture By manual adjustment of the relative flow-rates of carbon dioxide and air, *p*H of the culture was maintained between 7 0 and 7 2 In practice we found that approximately 10 per cent carbon dioxide air mixture is required to keep within this range

We thank Prof M G P Stoker and Dr I A Macpherson for supplying the *BHK* clone 13 cells, and Dr A Jones for his assistance with the chromosome analyses

REVERSIBLE ENERGY TRANSFORMATION WITH FILAMENTS PREPARED FROM A NATURAL MUSCLE

By Prof W. KUHN, I. TOTH and G EBNER
Institute of Physical Chemistry, University of Basle

(1) *Energy transformation with artificial filaments* It has been possible to obtain filaments made from macromolecular artificial substances which, embedded in a aqueous solution, dilate and contract under the influence of reversibly produced chemical changes[1], for example, dilation of a filament containing polyacrylic acid (and polyvinyl alcohol) on addition of sodium hydroxide and contraction on addition of hydrochloric acid ('*p*H-muscle')

It has been shown, furthermore, that a mechanical stretching of the filament will in the case of all these gels be associated with an increase in activity in the embedding medium of the reactants producing the contraction and a decrease in activity of the reactants producing the dilation ('temochemical' principle[2]).

The chemically induced contraction and the activity shift produced by mechanical stretching are related one to the other in such a way that the realization of equation (1) assures a quantitative transformation of free chemical into mechanical energy by use of these systems. The actual existence of a change in chemical equilibrium produced by mechanical deformation was demonstrated for the first time with the artificial cross-striated '*p*H-muscle' in 1958[3]. A change in *p*H in the embedding medium is in this case produced by a mechanical stretching of the filament. Analogous equilibrium changes were afterwards shown to occur with the homogeneous *p*H-muscle[4], the redox-muscle[1,2], the ion-precipitation-[1,2] and the $Cu^{\cdot\cdot}$-polyvinylalcohol-complex-formation-muscle[5].

In the case of the $Cu^{\cdot\cdot}$-polyvinylalcohol-muscle a mechanical stretching of the filament (shortened by the addition of $Cu^{\cdot\cdot}$-ions) produces a reversible increase of the $Cu^{\cdot\cdot}$-ions in the embedding medium (which may in this case be a buffer of $pH = 5\cdot9$).

(2) *Filaments prepared from a natural muscle.* It was interesting to find whether the temochemical principle is limited to the various kinds of artificial fibres mentioned or whether it is valid in a direct way also for filaments prepared from natural muscles. Strips made from the muscles of the earthworm (*Lumbricus terrestris*) were used for these experiments. In a first series of experiments (started in collaboration with D. H. Walters) the behaviour with copper ions was investigated, in another series, analogous tests, using calcium ions and hydrogen ions, were carried out.

(*a*) *Experiments with Cu.* For these experiments the earthworm was opened, washed, and the muscular system containing both longitudinal and transversal fibres treated for about 5 min. with *N* sodium hydroxide and subsequently with distilled water at 20° C. A muscle thus prepared was embedded in, for example, 5 c.c. of a 0·1 mol. sodium acetate buffer $pH = 5\cdot9$, the muscle's dimensions were then in a particular case $4\cdot57 \times 0\cdot5 \times 0\cdot2$ cm. On addition of $Cu^{\cdot\cdot}$-ions (copper sulphate or acetate) to the embedding solution the $Cu^{\cdot\cdot}$-ions are nearly completely absorbed by the muscle which thereby contracts. In the example mentioned the absorption by the muscle of $5\cdot25 \times 10^{-6}$ moles of $Cu^{\cdot\cdot}$ was associated with a change in length from 4·57 to 4·07 cm., that is, with a contraction by 11 per cent. The $Cu^{\cdot\cdot}$-ion concentration of the embedding liquid was then 9×10^{-3} moles/l., it was measured by means of a metallic copper electrode introduced into the embedding fluid and a reference saturated calomel electrode. When mechanically stretching the contracted filament from 4·07 to 5·58 cm. (that is, by 30 per cent) an increase of the $Cu^{\cdot\cdot}$-ion concentration in the embedding liquid was observed and quantitatively determined from the potential shift shown by the copper electrode. The potential shift mentioned indicates in a particular case a relative increase of the $Cu^{\cdot\cdot}$ activity of

$$\frac{d\,a_{Cu}}{a_{Cu}} = 0\cdot165$$

The reversible increase of the $Cu^{\cdot\cdot}$ activity ascertained when stretching the earthworm muscle (partly contracted by $Cu^{\cdot\cdot}$) shows qualitatively the applicability to this system of the temochemical principle.

We mention that the activity changes of $Cu^{\cdot\cdot}$ and the contractions and dilations produced by $Cu^{\cdot\cdot}$ are completely reversible and that when $Cu^{\cdot\cdot}$ is removed, for example, by dilute hydrochloric acid at the end of a series of experiments, the earthworm muscle has the same properties, for example, the same contractility with various reagents, as it had before being used for $Cu^{\cdot\cdot}$ experiments. In spite of this it was felt that experiments using calcium instead of copper ions would be nearer to 'natural' conditions.

(*b*) *Experiments with Ca.* For these experiments the earthworm muscular system was treated[6] with water at 80° C. for 1 min., washed three times at 20° C. with distilled water for 20 min. each time and then, still at 20° C., with 0·3 *N* acetic acid. The treatment with 0·3 *N* acetic acid produces a marked elongation of the muscle, for example, from 6·49 to 8·50 cm. The major part of the acetic acid absorbed is then removed by washing the muscle three or four times, each time with a new quantity of about 5 c.c. of distilled water. This removal of the acetic acid is accompanied by a partial contraction.

For the final observation the muscle was embedded in a 0·133 *N* solution of acetic acid. In a particular case its length was then 8·35 cm. After establishment of the equilibrium the volume of the embedding liquid was reduced to 1 c.c., and $1\cdot6 \times 10^{-5}$ mol. calcium acetate was added to the system. A part of the $Ca^{\cdot\cdot}$ added was absorbed by the muscle, producing a contraction by 0·62 cm. (8·35–7·73 cm.). In the embedding liquid the calcium concentration left was $0\cdot8 \times 10^{-2}$ mol. $Ca^{\cdot\cdot}$/l. and the *p*H was 3·78.

When this equilibrium was reached, the muscle was mechanically stretched in contact with the embedding fluid (of 1 c.c.) by a force $\mathfrak{K}$ of 13·5 gm. $= 1\cdot35 \times 10^{4}$ dynes. It produced an increase in length of 0·75 cm. An increase of the $Ca^{\cdot\cdot}$ concentration in the embedding liquid was found to occur from $0\cdot80 \times 10^{-2}$ to $0\cdot813 \times 10^{-2}$, that is, the relative increase was $\Delta(Ca^{\cdot\cdot})/(Ca^{\cdot\cdot}) = 0\cdot13/8\cdot0 = 0\cdot016$ or $1\cdot6 \pm 0\cdot2$ per cent. This concentration shift was measured with a flame photometer. The shift is reversible and can be repeated with the same muscle sample any number of times. Besides the increase of the $Ca^{\cdot\cdot}$-concentration a reversible increase of the *p*H by 0·04 units (from 3·78 to 3·82) was associated with the stretching mentioned.

The further analysis of these results shows that the stretching is associated (besides the shifts in the $Ca^{\cdot\cdot}$ and $H^{\cdot}$ concentrations mentioned) with an increase of the acetate ion concentration from $1\cdot60 \times 10^{-2}$ to $1\cdot626 \times 10^{-2}$, that is, with a relative acetate ion increase by $1\cdot6 \pm 0\cdot2$ per cent (practically equal to the relative $Ca^{\cdot\cdot}$-ion increase). The analysis shows, furthermore, that the stretching produces a release from the muscle of $1\cdot3 \times 10^{-7}$ gm. mol. or $2\cdot6 \times 10^{-7}$ gm.-equivalents of calcium acetate and an uptake by the muscle from the embedding liquid of about 10^{-5} gm. mol. of acetic acid.

The release of $Ca^{\cdot\cdot}$ and the uptake of acetic acid corresponds to the statement of the temochemical principle saying that a mechanical stretching of the filament is associated with an increase in the embedding medium of the activities of the substances producing a contraction ($Ca^{\cdot\cdot}$) and a decrease in the embedding medium of the substances (acetic acid) producing a dilation of the filament.

It is essential in the $Ca^{\cdot\cdot}$ experiment that the change in length of the filament produced by mechanical stretching does not greatly exceed the contraction which had been produced by the uptake of $Ca^{\cdot\cdot}$

For high mechanical stretching a change of the sign of the Ca effect is observed.

(3) *Quantitative.* It has been mentioned that the contraction of a filament produced by a chemical reagent and the chemical equilibrium change produced by a mechanical stretching of the filament are in the case of the artificial contractile systems quantitatively connected one to the other.

The quantitative formulation of the temochemical principle, adapted to the conditions prevailing in our experiments, reads

$$-\left(\frac{\partial n_{1,\text{tot}}}{\partial L}\right)_{\mathfrak{K}=\text{constant}} = \left(\frac{\partial \mathfrak{K}}{\partial L}\right)_{n_{1,\text{tot}}=\text{constant}} \frac{1}{RT\left(\frac{\partial \ln a_{1,\text{tot}}}{\partial L}\right)_{n_{1,\text{tot}}=\text{constant}}} \qquad (1)$$

In this equation $n_{1,\text{tot}}$ is the number of gm. mol. of the temochemical substance considered (Ca acetate or Cu acetate in our case) present in the total system (consisting of the gel and the embedding liquid), L the length of the filament. $\left(\frac{\partial n_{1,\text{tot}}}{\partial L}\right)_{\mathfrak{K}=\text{constant}}$ is the number of gm. mol. of the temochemically active substance (Ca acetate) added to the system (to gel plus embedding liquid), divided by the change in length of the filament, whose charge $\mathfrak{K}$ is kept at a constant value. In our experiment where the addition of 1.6×10^{-5} mol. Ca acetate produced a contraction by 0.62 cm. of the uncharged filament we had obviously

$$-\left(\frac{\partial n_{\text{Ca acetate}}}{\partial L}\right)_{\mathfrak{K}=0} = +2.6 \times 10^{-5}\ \text{mol cm}^{-1} \qquad (1a)$$

$\left(\frac{\partial \mathfrak{K}}{\partial L}\right)_{n_{1,\text{tot}}=\text{constant}}$ on the right-hand side of equation (1) is the quotient of the increase $\partial\mathfrak{K}$ of the force acting on the filament and the change in equilibrium length observed under the condition that the filament is in each stage of the experiment in equilibrium with the embedding liquid and that the number of gm. mol. of all substances present in the system (filament plus embedding liquid) is constant.

In our experiment where a force of 1.35×10^4 dynes produced an increase in length $dL = 0.75$ cm., we had:

$$\left(\frac{\partial \mathfrak{K}}{\partial L}\right)_{n_{1,\text{tot}}=\text{constant}} = 1.8 \times 10^4\ \text{dynes cm}^{-1} \qquad (1b)$$

R and T in equation (1) are the universal gas constant and the absolute temperature respectively.

$\left(\frac{\partial \ln a_1}{\partial L}\right)_{n_{1\,\text{tot}}=\text{constant}}$ is the activity change, divided by the increase in length of the temochemical substance (in our case of calcium acetate) produced, if the filament is mechanically stretched at a constant composition of the total system. In our experiment where calcium acetate is the temochemical substance, we have

$$\frac{\partial \ln a_1}{\partial L} = \frac{\partial \ln a_{\text{Ca}}}{\partial L} + \frac{2\partial \ln a_{\text{Ac}^-}}{\partial L}$$

When stretching the muscle in our experiment we had, with an increase in length $(dL) = 0.75$ cm.

$\frac{d\,C_{\text{Ca}}}{C_{\text{Ca}}} = \frac{d\,C_{\text{Ac}^-}}{C_{\text{Ac}^-}} = \frac{dc}{c} = 0.016$ and therefore, if $\bar{f}$ is the mean ion activity coefficient of the Ca - and acetate-ions

$$\frac{\partial \ln a_{1,\text{tot}}}{\partial L} = 3\frac{d\ln c\bar{f}}{\partial L} = \frac{3 \times 0.016}{0.75}\left(1 + \frac{\partial \ln \bar{f}}{\partial \ln c}\right)$$

An estimate of $\frac{\partial \ln \bar{f}}{\partial \ln c}$ by help of the theory of electrolytes gives for the embedding solution $\frac{\partial \ln \bar{f}}{\partial \ln c} \simeq -0.2$ to 0.4. Using the latter value we get

$$\frac{\partial \ln a_{1,\text{tot}}}{\partial L} = 0.038\ \text{cm}^{-1} \qquad (1c)$$

If we use the numerical values indicated in equations (1b) and (1c) we obtain with $RT = 2.4 \times 10^{10}$ ergs for the right-hand side of equation (1)

$$\frac{\left(\frac{\partial \mathfrak{K}}{\partial L}\right)_{n_{1,\text{tot}}=\text{constant}}}{RT\left(\frac{\partial \ln a_{1,\text{tot}}}{\partial L}\right)_{n_{1,\text{tot}}=\text{constant}}} = 2.0 \times 10^{-5}\ \text{mol cm}^{-1} \qquad (2)$$

The agreement of this value with equation (1a), that is, the experimental verification of the temochemical equation (1), is obvious. The moderate deviation is accounted for by the inaccuracy of the measurements, the uncertainty with respect to the activity coefficients used, and, in particular, to the fact that finite values for $d\mathfrak{K}$, dL, $d\ln a_{1,\text{tot}}$ had to be used instead of infinitely small differences for the determination of the differential quotients in (1a), (1b) and (1c). They should all have been determined in the limes $\mathfrak{K} = 0$ (or all in the neighbourhood of another definite value of $\mathfrak{K}$ chosen). It has been mentioned that even a change of sign may occur if large instead of small deformations are produced.

The thermodynamical consideration leading to equation (1) is similar to the derivation given in a recent paper[4] of a relation which is substantially and formally analogous to equation (1) but somewhat less adapted for the direct use in our experiments.

(4) *Reversible and quantitative energy transformation.* As the derivation of equation (1) is based on the second law of thermodynamics, applied to a cycle involving mechanical and chemical dilations and contractions of the filament, the possibility to transform free chemical energy (or osmotic energy) quantitatively into mechanical energy is assured for each system which obeys equation (1).

As we have mentioned in the introduction, the validity of equation (1) has been confirmed for the cross-striated and the homogeneous *p*H-muscle, the polyvinylalcohol-2-methylnaphthochinon-hydrochinon-redox-muscle and the polyvinylalcohol-Cu -complex formation muscle. We can state now that the validity also exists for the system consisting of the earthworm muscle in a dilute acetic acid–calcium acetate solution, that is, the teinochemical principle holds both in its qualitative and its quantitative form also for filaments made from a natural muscle The structure and properties of these filaments are such that they are able to transform reversibly into mechanical energy the free energy of dilution of Ca - (or Cu -) solutions or the free energy of chemical reactions leading to a formation or elimination of these substances After that the possibility of a quantitative energy transformation in the elementary process of muscular contraction has to be reckoned with As our experiments were carried out in the absence of adenosine triphosphoric acid (ATP) they prove that the structure of the earthworm muscle realized in our experiments permits the contractions, dilations and transformation of Ca -ion dilution energy into mechanical energy without participation in any way of ATP On the other hand, this does not exclude that ATP plays an important part in the natural muscle contraction as well in the elementary contraction process as in ion transport phenomena preparatory to the contraction

(5) *Generalization* The observation reported when describing the earthworm muscle-Ca -acetate-acetic acid system, that a mechanical stretching is associated with a release of Ca acetate and simultaneously with an uptake of acetic acid from the embedding liquid (and that the muscle correspondingly contracts on addition of Ca acetate and dilates on addition of acetic acid) shows that the same contractile filament is teinochemically active at the same time for more than one kind of substance present in the system It is therefore to be expected that the same natural muscle filament will be able to transform into mechanical energy also the free dilution energies of further substances, for example of Na^{+}, Mg^{++} and K^{+}-ions and possibly of ATP. A teinochemical equation of the form of equation (1) will be valid for each substance, for example for potassium chloride, sodium chloride, etc , by the addition of which a contraction or dilation of the filament can be produced

It will be seen, furthermore, that the nominator

$$\left(\frac{\partial \mathfrak{R}}{\partial L}\right)_{n_{1,\mathrm{tot}}} = \text{constant}$$

on the right-hand side of equation (1) will be the same for all these expressions. There will therefore be an interdependence of equation (1) valid for the individual teinochemical substances occurring in the system

So far as the contraction mechanism is concerned no direct conclusion can be drawn from the validity of equation (1) The validity proves the quantitative transformation into mechanical energy of the free dilution energy of the substance involved but nothing about the mechanism

The parallelism in the general behaviour between the strips made from the earthworm muscle and the artificial fibres made of polyvinylalcohol, polyacrylic acid, etc , all obeying equation (1) suggests only in a non-conclusive way, that is, as a possibility, some parallelism of the contraction mechanisms

However this may be, the establishment and experimental proof of equation (1) prove also, for filaments prepared from a natural muscle, the possibility of a quantitative and reversible energy transformation Due to the verification of this equation the observation of the activity changes produced by mechanical stretching should be an efficient tool to ascertain or to exclude the significant participation in the mechanical energy creation of any given muscle constituent

HELICAL MODELS OF FEATHER KERATIN STRUCTURE

By R. D. B. FRASER and T. P. MACRAE

Division of Protein Chemistry, Commonwealth Scientific and Industrial
Research Organization, Parkville, Victoria, Australia

IN a recent publication dealing with the structure of feather keratin[1] it was suggested that many features of the elaborate X-ray diffraction diagram given by this material could be explained in terms of linear aggregates of small β-crystallites A sheet-like arrangement of crystallites similar to that proposed by Bear and Rugo[2] was shown to account for certain features of the low-angle diffraction pattern, but it was pointed out that a helical arrangement was equally possible

Although our analysis of helical arrangements is not yet complete, the recent discovery by Filshie and Rogers[3] that feather keratin contains fibrillar elements (microfibrils) about 30 Å in diameter (Fig 1) prompts us to direct attention to the possibility that these microfibrils may be helical aggregates of β-crystallites This view contrasts with that of Schor and Krimm[4], who consider that it is the β-chains rather than β-crystallites which are arranged in a helical manner. These authors have described a detailed model for feather keratin and consider that it is the only one which satisfies the requirements of the experimental data. We have examined the diffraction properties of this model, and have not been able to reconcile it with such features as the strong 10 Å group of equatorial and near equatorial reflexions, the 'net' diagram obtained by Bear and Rugo[2], the very considerable intensity of the 24 Å meridional reflexion and the strong group of reflexions about 2 Å The latter are more indicative of a conventional pleated-sheet chain arrangement than the polar pleated-sheet envisaged by Schor and Krimm We have thus been led to consider an alternative possibility derived as follows

The great majority of the reflexions in the X-ray diagram of feather keratin may be indexed on an axial period *b* of 95 Å and at lower angles of diffraction meridional reflexions are, with minor exceptions, confined to layer lines with k equal to a multiple of four This suggests that the primitive helix has a pitch of 95 Å with approximately 4 nodes per turn, as illustrated by the circles and full line in Fig 2*a* The appearance expected in cross-section in electron micrographs would depend on the distribution of scattering matter about each node, and in the example shown in Fig 2*a* would give the appearance of five sub-fibrils within each microfibril as in Fig 2*d* The distribution could equally well have been drawn to give any number of sub-fibrils

At wider angles of diffraction meridional reflexions occur on layer lines other than those with values of k which are multiples of 4 and in addition a strong meridional reflexion with $k = 1$ appears when feather keratin is stained with mercuric acetate or silver nitrate It follows, therefore, that the helix shown in Fig 2*a* is only a pseudo-structure, that is to say, the crystallites within one turn of the helix are not identical The pattern of residues and precise location must differ from crystallite to crystallite in such a way that the axial projection of the structure repeats only after 95 Å or some multiple of this distance

Two features of the X-ray diagram which appear to be related are the restriction of diffraction to even layer lines in the near equatorial reflexions around 10 Å and the occurrence of a 'net' diagram with the restriction $k/2 + h = 2n$, where n is integral, in samples which have been partially heat denatured[2] or stained with certain heavy atoms[1] Two explanations of these features appear possible They may be due to external interference between microfibrils or alternatively to the presence of two crystallites about each node of the primitive helix as, for example, in Fig 2*b* and *c* The fact that the crystallites are not identical has been emphasized by numbering them in two of the many possible ways consistent with the result of staining with mercuric acetate or silver nitrate

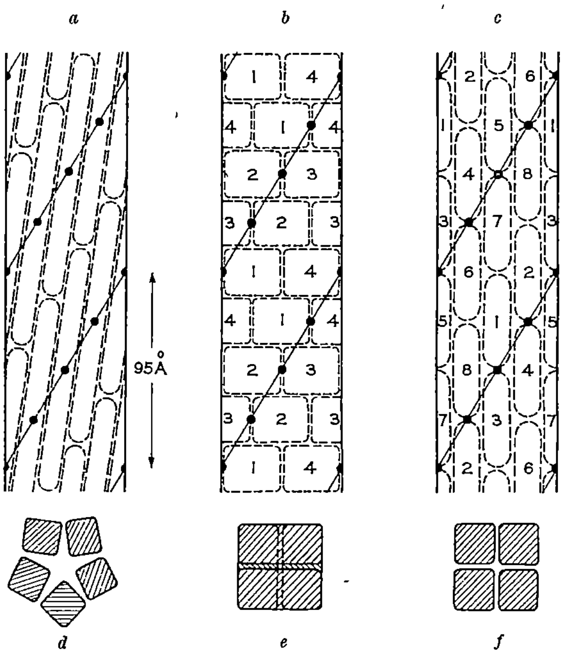

Fig 2 *a* *b*, *c*, Radial projections of helical models for feather keratin, the black circles joined by a continuous line represent the primitive helix In *a* one β-crystallite is arranged about each node, in *b* and *c* there are two crystallites about each node, *d*, *e*, *f*, the appearance of *a*, *b*, *c* respectively in cross-section (not to scale)

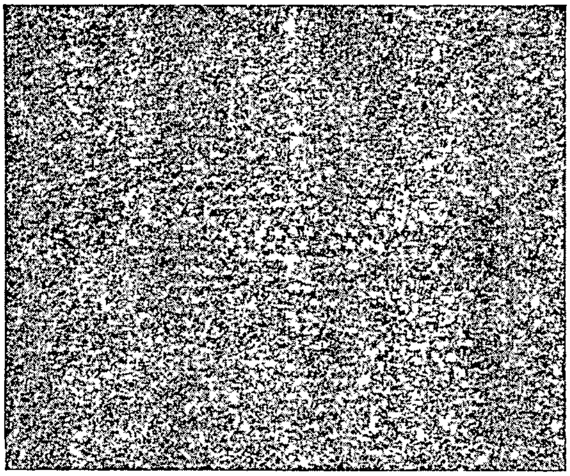

Fig 1 Electron micrograph showing microfibrils about 30 Å in diameter in a cross section of feather keratin (ref 3)

It is not possible to decide at present whether the polypeptide chain of the protein sub-units in feather keratin is confined to one crystallite or passes through many crystallites The crystallites in Fig 2*a* have quite arbitrarily been drawn in such a way that they are in contact with their neighbours The considerable intensity of the 24 Å meridional reflexion would be well explained if in the direction of the fibre axis the crystallites were separated by regions of specific but irregular configuration

ELECTRON TRANSPORT SYSTEMS IN PURPLE BACTERIA

Hydrogenase and Light-stimulated Electron Transfer Reactions in Photosynthetic Bacteria

CHROMATOPHORES isolated from purple bacteria are capable of producing adenosine triphosphate (ATP) from adenosine diphosphate and inorganic phosphate by an anaerobic light-dependent process[1] and, in addition, these pigmented particles catalyse a number of oxidation-reduction reactions, some of which are activated or stimulated by illumination[2]. For example, chromatophores can effect a net 'photo-reduction' of nicotinamide adenine dinucleotide (NAD) in the presence of succinate[3,4], reduced flavin mononucleotide ($FMNH_2$) (refs 3 and 4), or a mixture of ascorbic acid + 2,6-dichlorophenolindophenol (DCPIP) (ref 5) serving as electron donor Similarly, 'photoreduction' of fumarate in the presence of ascorbic acid + DCPIP has been reported[6] These light-stimulated oxidation-reduction reactions have been usually[4,5,7] interpreted in terms of 'non-cyclic' electron-transfer mechanisms Thus, it is postulated that the action of light on the photochemical apparatus causes production of a 'photoreductant' and a 'photo-oxidant', presumably, the acceptor (NAD or fumarate) is reduced by the photoreductant, while the added electron donor (succinate, $FMNH_2$, etc) is oxidized by the photo-oxidant

Thus far, there is no unambiguous direct evidence for the 'non-cyclic' electron-flow interpretation of the oxidation-reduction reactions cited, and we believe that the present available facts are not incompatible with other possible mechanisms One such alternative is that the added electron donor reduces the acceptor by a direct (enzymatic) reaction which is promoted by ATP, or energy-rich precursors of ATP, produced by illumination[8] The concept of energy-dependent electron flow from succinate to NAD (in mammalian mitochondria), has been advanced by Chance *et al* [9], who have also proposed that a similar process can account for kinetic data, obtained by dynamic spectrophotometry, on light-stimulated NAD reduction in intact cells of purple bacteria[8] In this communication, we summarize new experimental results which support the view that energy-dependent electron transfer is the basis of the light-stimulation of certain oxidation-reduction reactions observed in the purple bacterium *Rhodospirillum rubrum*, or in chromatophores derived from this organism

During photosynthetic growth in a medium[10] containing malate (or succinate) and glutamate as the nitrogen source, *R rubrum* produces large quantities of molecular hydrogen and the collected cells contain an active hydrogenase. The enzyme in cell-free extracts (made by sonication, passage through a French pressure cell, or grinding cells with alumina) is associated with the particulate chromatophore fraction[11], is remarkably stable toward oxygen, and is capable of reducing a variety of electron acceptors with hydrogen in darkness (namely, benzyl viologen, janus green *B*, nile blue *A*, methylene blue, brilliant cresyl blue, thionine, *N*-methylphenazonium methosulphate, toluylene blue, DCPIP, *p*-benzoquinone, ferricyanide) Frenkel and Cost (following communication) have shown that the hydrogenase in *R rubrum* chromatophore preparations also reduces mammalian cytochrome *c* Metal-chelating agents (*o*-phenanthroline, α,α′-dipyridyl, diethyldithiocarbamate) and *p*-chloromercuribenzoate, do not inhibit the oxidation of hydrogen with artificial electron acceptors and the hydrogenase activity is not significantly diminished by (anaerobic) dialysis[12]. Although FMN is not reduced at an appreciable rate by the particles, treatment of the latter with sodium lauryl sulphate or sodium deoxycholate leads to significant hydrogenase activity with this nucleotide (Fig 1) and also with flavin adenine dinucleotide It thus appears that added flavin nucleotides are not readily accessible to the hydrogenase enzyme in the usual type of chromatophore preparation

Untreated particles do not reduce NAD with hydrogen, but after exposure to deoxycholate the pyridine nucleotide can be reduced as shown by Fig 1 and Table 1 The reaction requires the presence of FMN and a trapping system (lactic dehydrogenase (LDH) and pyruvate) for continual reoxidation of the $NADH_2$ produced Control experiments with the complete system showed that lactate formation under a gas-phase of helium was approximately one-tenth that observed under hydrogen In a number of experiments, the molar quantity of hydrogen utilized after addition of the trapping system (subsequent to reduction of the FMN) corresponded closely to that of lactate formed For unknown reasons, the total amount of hydrogen consumed by the complete system in the experiment of Table 1 was lower than that expected (that is, approximately 6 5 µmoles) In any event, the present results indicate that NAD can be reduced in darkness by chromatophore preparations through the following sequence

$$H_2 \rightarrow FMNH_2 \rightarrow NADH_2$$

Participation of flavins as intermediary carriers in the reduction of NAD by hydrogen in other microbial preparations has been reported by several investigators[13]. The one-electron dye benzyl viologen ($E'_0 = -0\ 359$ V) can apparently substitute for flavins, and possibly other carriers, in certain of these systems[14] and we have observed a similar reaction in untreated chromatophores of *R rubrum*

Although the FMN redox couple has a more positive standard potential ($E'_0 = -0\ 22$ V) than that

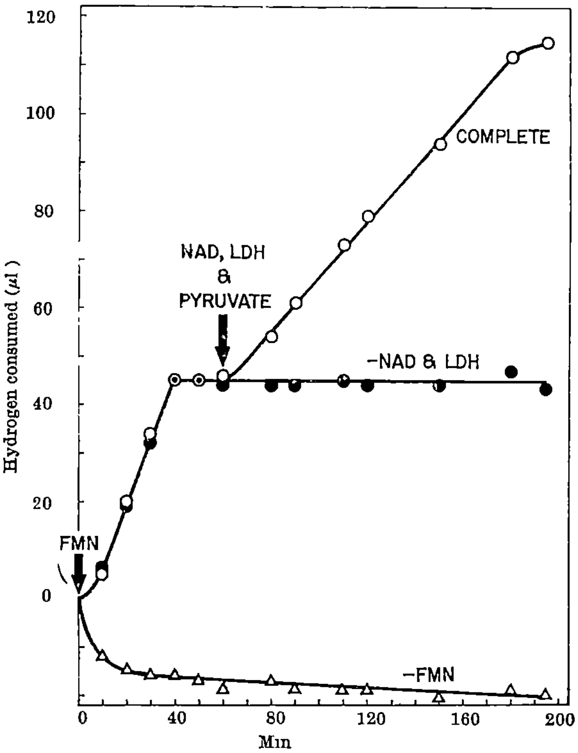

Fig 1 FMN-dependent dark reduction of NAD with molecular hydrogen by deoxycholate-treated particles from *R rubrum* Complete system potassium phosphate buffer *p*H 6 8, 100 µmoles, FMN, 2 µmoles, NAD, 1 µmole, sodium pyruvate, 5 µmoles, lactic dehydrogenase (LDH), 200 µg, sodium deoxycholate, 6 mg, *R. rubrum* particles containing 0 99 mg bacteriochlorophyll, water to make 2 0 ml final volume, 0 1 ml of 20 per cent potassium hydroxide in the centre-well, gas phase, hydrogen, temperature, 30° C FMN and other additions were introduced at the times indicated by the vertical arrows NAD, LDH and pyruvate were added at zero time to the control vessel not containing FMN The stoichiometry of hydrogen consumption and NAD reduction (as measured by lactate formation) in this experiment is shown in Table 1

Table 1 HYDROGEN UTILIZATION AND NAD REDUCTION BY *R rubrum* PARTICLES

Conditions	H_2 utilized (µmoles)	Lactate formed (µmoles)
Complete system	5 1	5 0
FMN omitted	0	0
FMN and NAD omitted	0	0
NAD and LDH omitted	1 9	0 2

Experimental conditions as described for Fig 1 The experiment was terminated at 190 min and lactate determined by a modification of the Barker–Summerson method (ref 20)

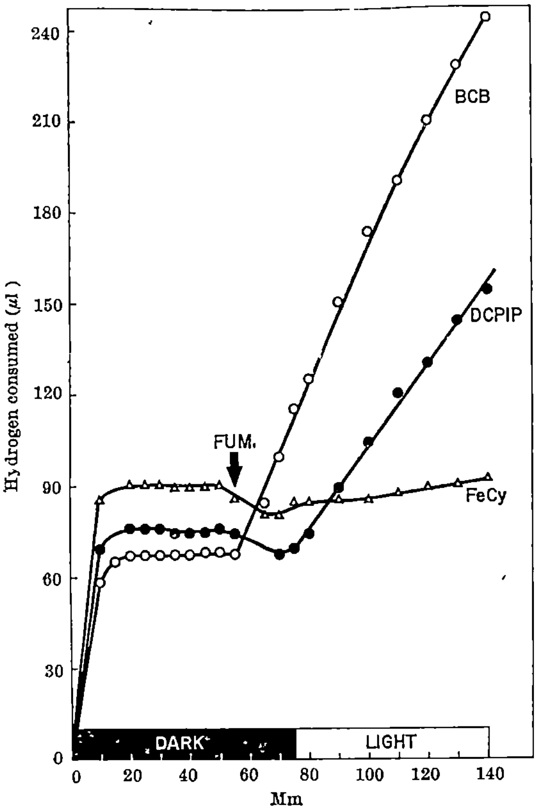

Fig 2 Oxidation of hydrogen with fumarate by *R rubrum* particles in the presence of redox carriers, light-stimulated catalysis by DCPIP

Reaction mixture *tris* (hydroxymethylaminomethane) *p*H 8 0, 150 μmoles, potassium phosphate *p*H 7 6, 3 5 μmoles, sodium fumarate, 40 μmoles, washed *R rubrum* particles (from alumina-ground cells) containing 0 98 mg bacteriochlorophyll, water to make 2 0 ml final volume, 0 2 ml of 20 per cent potassium hydroxide in centre-well, gas phase, hydrogen, temperature, 30° C, light intensity, 1,000 foot-candles, redox carriers (approx 4 μmoles) were added at zero time and fumarate at 55 min, brilliant cresyl blue (BCB), potassium ferricyanide (FeCy)

of the NAD couple ($E'_0 = -0\ 32$ V), it is apparent that the potentials of the two systems can overlap, particularly if the FMN is maintained in the reduced state by hydrogen, and NAD in the oxidized state by the trapping system Frenkel[3,4] has observed a light requirement for reduction of NAD by chromatophores with chemically reduced FMN (or with succinate) as the electron donor, since a trapping system was not used in his experiments, it seems possible that light was required to provide energy for overcoming an unfavourable potential difference between the two redox couples Presumably, a similar light-stimulation of NAD reduction by hydrogen (mediated by FMN) may be demonstrable under appropriate experimental conditions

Chromatophore preparations from *R rubrum* do not reduce fumarate with molecular hydrogen unless a suitable electron carrier is added As is illustrated in Fig 2, the dye brilliant cresyl blue ($E'_0 = +0\ 047$ V) catalyses the reduction of fumarate by hydrogen in darkness, and illumination has no significant effect on the rate of the reaction Similar results are observed with mediators of low redox potential (for example, with janus green *B*, and with FMN in deoxycholate-treated preparations) Although the rate of fumarate reduction by hydrogen (using untreated particles) varies widely, depending on the electron-carrier added, it is clear that chromatophores show a potent fumaric reductase activity which can be readily coupled to the hydrogenase Furthermore, the general properties of the coupled system in *R rubrum* particles, including lack of inhibition by malonate, closely resemble those described earlier[15] for preparations derived from certain non-photosynthetic anaerobes

Reduction of fumarate by hydrogen also occurs in the presence of catalytic quantities of the other dyes (but not ferricyanide) noted to be reducible by the hydrogenase In many instances, a definite acceleration in rate is caused by illumination, particularly when the mediating dye has a redox potential significantly higher than that of the fumarate–succinate couple ($E'_0 = +0\ 031$ V) This is especially clear-cut with DCPIP ($E'_0 = +0\ 22$ V) The latter is rapidly reduced by the hydrogenase of washed chromatophore preparations, but the dye is unable to act as an efficient catalyst for fumarate reduction in the dark Addition of 5×10^{-3} M Mg^{++} induces appreciable activity in darkness, but in the absence of such ions dark activity is usually negligible From Fig 2 it can be seen that when Mg^{++} is not added, utilization of hydrogen with fumarate (mediated by DCPIP) is observed if the system is illuminated Owing to the presence of excess hydrogenase, the dye remains in the reduced (leuco) form during the course of the reaction Suitable controls, containing sufficient added hydrogenase to generate $DCPIPH_2$, showed that the light-activated reduction of fumarate is abolished by heating the chromatophore preparations

The 'photohydrogenase' activity catalysed by DCPIP appears to be insensitive to antimycin *A* and amytal, and is appreciably stimulated by atebrin Relatively high concentrations of 2,4-dinitrophenol are required to inhibit photophosphorylation by chromatophores[16], and this uncoupler at levels of 0 01–0 02 M causes marked inhibition of the 'photoreduction' of fumarate by hydrogen Another inhibitor of phosphorylation, 2-nonyl-4-hydroxyquinoline-*N*-oxide, also was found to be effective, but variable results were obtained using different particle preparations Details of experiments with the foregoing and other inhibitors of electron transfer and photophosphorylation will be given elsewhere

Since the dye-mediated reduction of fumarate by hydrogen can occur in darkness, it is evident that the overall reaction does not necessarily require light, or entities produced by illumination The fact that illumination stimulates when the mediating electron-carrier has a high redox potential (relative to the fumarate–succinate couple) suggests to us that the action of light is concerned with providing energy for driving hydrogen transfer against an unfavourable thermodynamic gradient (for example, from $DCPIPH_2$ to fumarate) Washed chromatophores also exhibit a light-stimulated hydrogen consumption with fumarate in the presence of catalytic amounts of *N,N,N',N'*-tetramethyl-*p*-phenylenediamine ($E'_0 = \sim +0\ 26$ V) The latter has been used as an electron donor for energy-linked reduction of NAD and ubiquinone in mammalian mitochondria[17].

Recent experiments in this laboratory have shown that *R rubrum* can convert organic substrates to carbon dioxide and hydrogen by means of an anaerobic light-dependent citric acid cycle, and this process has been interpreted as a physiological regulatory mechanism for controlling 'energy balance'[18,19] It is significant, in this connexion, that photoproduction of H_2 is markedly inhibited by a variety of agents (antimycin *A*, 2,4-dinitrophenol, redox dyes) known to interfere with photophosphorylation[19] Alternative hypotheses concerning the precursor of the hydrogen evolved visualize either a photoreductant created by the photochemical apparatus or NADH$_2$ produced by reactions of the citric acid cycle[18,19] According to our present views, the light-dependency of hydrogen formation by the hydrogen-evolving enzyme system of intact cells could be accounted for by supposing that energy-rich intermediates created by light facilitate a 'dark' enzymatic conversion of NADH$_2$ to NAD + H$_2$

In summary the concept of light-dependent 'non-cyclic' electron transfer, as a means of generating net reducing power of hydrogen, is invoked in hypotheses of the mechanism of bacterial photosynthesis largely on the basis of comparative biochemical argument, but lacks critical experimental support A more plausible conception, suggested by the present and other observations, is that 'photoreduction' of NAD (or fumarate) and photo-evolution of hydrogen occur through promotion of 'dark' oxidation-reduction reactions by energy-rich intermediates, produced by the interaction of light with the photochemical apparatus Accordingly, the 'accessory hydrogen donor', characteristically required for growth of photosynthetic bacteria, may in some instances (for example, succinate) serve as a direct source of hydrogen for reduction of pyridine nucleotides only if light energy is provided

Reduction of Mammalian Cytochrome *c* by *Rhodospirillum* hydrogenase

GEST[1] originally described a particulate hydrogenase from *Rhodospirillum rubrum* and now Bose and Gest have reported on a number of reactions mediated by this enzyme system (preceding communication).

In the search for light-induced reactions of molecular hydrogen with naturally occurring electron transport systems mediated by *Rhodospirillum* chromatophores, it was observed that isolated chromatophores readily reduce mammalian cytochrome *c* with molecular hydrogen in the dark Well-washed preparations, in the absence of molecular hydrogen or of suitable electron donors, show little or no activity in reducing added cytochrome *c* (Fig 1) Hydrogenase systems isolated from other organisms have been shown to be capable of reducing mammalian cytochrome *c* like that isolated and purified from *Clostridium pasteurianum*[2], nevertheless, the reported activity of *Rhodospirillum* chromatophores may be of possible interest for further investigations of light and dark reactions in this organism involving molecular hydrogen

A typical reaction course followed spectrophotometrically is given in Fig 1 With higher concentrations of cytochrome *c* and of chromatophores the reaction can be followed manometrically The initial rates are about 5 μM of cytochrome *c* reduced per μM bacteriochlorophyll per hour, or 0 05–0 1 μM of cytochrome *c* reduced per hour per milligram dry weight of material precipitable by cold trichloroacetic acid Thus far it has not been possible to increase this rate appreciably by the addition of a number of co-factors including flavin mononucleotide or flavin adenine dinucleotide Carbon monoxide (1 atm CO + 20 mm (Hg) H$_2$) does not inhibit the reported hydrogenase activity, nor does it inhibit the activation of the enzyme

The enzyme preparation is stable for several months at —10° C when stored in dilute aqueous buffers Under the same conditions the ability of the chromatophores to carry out photo-phosphorylation or light-induced electron transport reactions involving nicotinamide adenine dinucleotide (NAD) have been

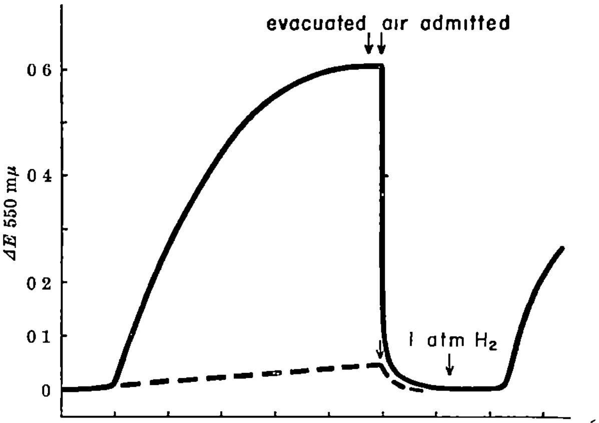

Fig 1 Reduction and oxidation of cytochrome *c* by *Rhodospirillum* chromatophores

Chromatophores prepared from three-day-old bacterial cultures grown anaerobically in the light Method of preparation described in ref 6 Chromatophores suspended in 0 1 M potassium glycylglycine *p*H 7 7 Optical density of chromatophore suspension at 880 mμ = 1 72 Additions 0 08 μM cytochrome *c* (from horse heart, Sigma) Anaerobic cuvettes evacuated (- - -), or evacuated and flushed with hydrogen (——)

lost Nevertheless, even with fresh preparations which can carry out such light-induced reactions, we have not been able to demonstrate a light-induced electron transport from reduced mammalian cytochrome *c* to NAD as reported by Vernon[3], or a transfer from reduced *Rhodospirillum* cytochrome *c* (cytochrome c_2 (ref 4)) to NAD Studies on the reduction of cytochrome c_2 by *Rhodospirillum* hydrogenase are in progress

Reduced mammalian cytochrome *c* is rapidly re-oxidized by molecular oxygen[5] (Fig 1), a reaction which is far more rapid than the hydrogenase reaction Manometrically it is possible to establish the stoichiometry of these reactions for a given amount of cytochrome *c* leading to a net oxidation of molecular hydrogen by oxygen In molar ratios

Hydrogen consumed cytochrome *c* (Fe^{+++}) reduced = 2 4 (hydrogenase)

Oxygen consumed cytochrome *c* (Fe^{++}) oxidized = 1 4 (oxidase)

Overall reaction $2 H_2 + O_2 = 2 H_2O$

This reaction sequence of alternate reduction and oxidation of cytochrome *c* can be continued many times at 25° C before appreciable irreversible inactivation of the hydrogenase takes place

The picture of the chromatophore which emerges from other studies and these observations is that of a complex photochemical and dark electron transport system The latter, however, is studied here with a 'foreign' electron carrier. It will be of considerable interest to find the natural carrier in this system which readily can react with molecular hydrogen in the chromatophore under physiological conditions

We thank Dr H Gest for a generous sample of cytochrome c_2 and Drs Gest and E Lindstrom for advice

This investigation was supported by grants from the National Institute of Allergy and Infectious Diseases (*E*–2218) and the U S National Science Foundation (*G*–9888)

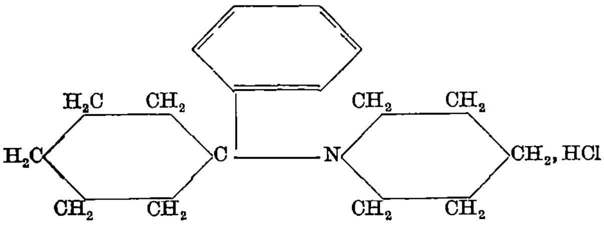
EFFECTS OF PHENCYCLIDINE ON THE RADIOSENSITIVITY OF MICE

By LIEUT -COLONEL J H. WILKINS and J H BARNES

Medical Research Council, Radiobiological Research Unit, Harwell, Berks

PHENCYCLIDINE (Cl-395) I-(I-phenylcyclohexyl) piperidine monohydrochloride is a white solid, freely soluble in water and ethanol It was synthesized in the Detroit Laboratories of Parke, Davis and Co about four years ago



The drug has undergone investigation in several animal species[1–6], revealing potent analgesic properties It can be administered orally, intramuscularly or intravenously The drug completely blocks somatic sensory perception[7] and causes vasomotor and respiratory stimulation It acts on the central nervous system by stimulation or depression, the effect varying according to the species of animal and dosage used excitement is predominantly shown in rodents whereas in most other species depression is the principal effect Phencyclidine cannot be regarded as a hypnotic or a sedative, and is best classified as a psychotropic drug

Previous studies with goats[5] showed promising results As it was intended to use the drug as an induction analgesic agent in certain radiation experiments it was necessary to discover whether phencyclidine possessed any protective effects With this objective in view experiments with mice were undertaken

Experiments I and II were designed to discover the general effects of the drug on mice before and after irradiation All injections were given intraperitoneally. Female mice of *R* stocks, weighing between 20 and 25 g, were used at the age of 14 weeks

Experiment I Effects at various dose-levels in unirradiated *R* mice

2 mg/kg and below no apparent effect

4–14 mg/kg after a few minutes disoriented In lower part of range, some signs of excitement In higher part of range, often unable to stand Effects lasting about 1 h

20 mg/kg after a few minutes, very unsteady and depressed There was recovery after about 2 h

80 mg/kg and higher convulsions, collapse and death

At the higher dose-levels, œdema of the lungs was noticeable at post-mortem

The dose giving the greatest degree of depression was 20 mg/kg

Experiment II Effects at various dose-levels in lethally irradiated *R* mice

Groups of ten mice each were given respectively 2, 5, 20 and 60 mg/kg of the drug intraperitoneally 15 min later they were exposed, in groups of five, to 1,025 r X-irradiation, which normally gives more than 95 per cent mortality in controls within 30 days Ten controls were included

The conditions of the X-irradiation were as follows 250 kV, 15 m amp , half-value layer, 1 2 mm copper, distance to underside of partitioned box, 60 cm dose-rate, 73 6 r /min

All five treatments (that is, controls, 2, 5, 20 and 60 mg/kg) were represented in each box during each irradiation

Controls	all died 8–13 days
2 mg/kg	all died 9–13 days
5 mg/kg	all died 5–12 days
20 mg/kg	all died 6–14 days
60 mg/kg	one died on first day, remainder died 7–24 days

The reaction to the drug of irradiated mice differed from that of the unirradiated Generally speaking, the irradiated mice showed more depression, which increased in extent as the dose of the drug was increased

2 mg/kg	showed little effect
5 mg/kg	caused disorientation with difficulty in standing
20 mg/kg	partial collapse with depression
60 mg/kg	more collapsed with greatest depression

It was decided that to detect any protective effect LD_{50} doses of X-irradiation would be necessary

Experiment III Effect of phencyclidine on the $LD_{50(30)}$ of mice exposed to X-irradiation

The mice were randomized with regard to sex, weight and age Groups of ten mice were irradiated at a dose-rate of 54 5 r /min so as to receive a total dose of 650 r , 725 r , 800 r , 875 r and 950 r respectively in one fraction

Control mice received 0 3 ml of saline intramuscularly and the treated groups 0 3 ml of a diluted solution of phencyclidine, so that each mouse received an equivalent of 4 mg/kg

Irradiation took place 0 5 h after the injections and the X-ray beam was directed upwards towards the partitioned boxes Treated and control mice were irradiated simultaneously

The conditions of irradiation were as follows 250 kV , 14 m amp , half-value layer, 1 2 mm copper, distance to underside of boxes, 72 cm, dose-rate, 54 5 r /min

Table 1 and Fig 1 give the mortality response of control and treated groups

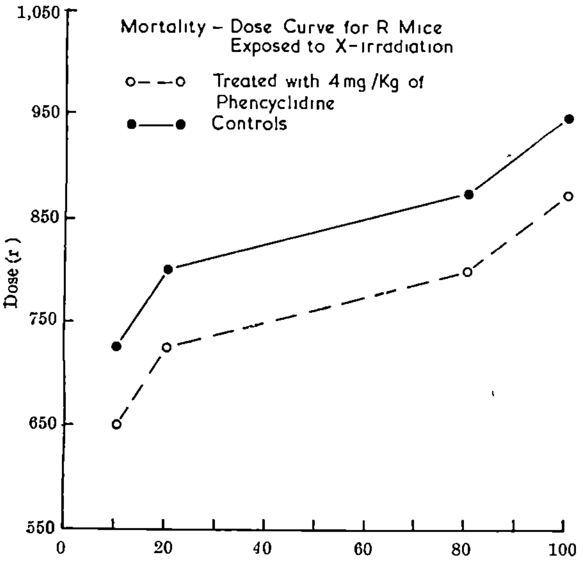


Fig 1

Table 1 30-DAY MORTALITY RESPONSE

Dose (r)	Controls	Phencyclidine-treated
650	1/10	0/10
725	2/10	1/10
800	8/10	2/10
875	10/10	8/10
950	10/10	10/10
$LD_{50(30)} \pm S\ E$	752 5 r ± 15 8 r	828 0 r ± 15 9 r
Approx 95 per cent limits of $LD_{50(30)}$	724 r 785 r	799 r 861 r

Table 2 gives the cumulative mortality over the period of 30 days

Table 2 30-DAY CUMULATIVE MORTALITY

Days after irradiation	Controls No dead	Treated with phencyclidine (Cl-395) No dead
8	5	—
10	3	—
11	1	1
14	16	13
15	1	3
16	2	2
18	1	—
21	1	1
28	—	1
30	1	—
Total	31	21

The $LD'_{50(30)}$ for mice for this experiment was calculated to be as follows

Controls	752 5 r
Phencyclidine-treated	828 0 r

The LD_{50}s are significantly different ($P < 0\ 001$)

It was concluded that phencyclidine at 4 mg/kg increased the $LD_{50(30)}$ by 75 5 r and had a slight protective effect on the mortality response of *R* mice

We thank the Director, Army Veterinary and Remount Services, the War Office and the Director, Radiobiological Research Unit, Harwell, for permission to publish this article We also thank Messrs Parke, Davis and Co , who kindly supplied the drug, and Mr M J Corp, who arranged the irradiations

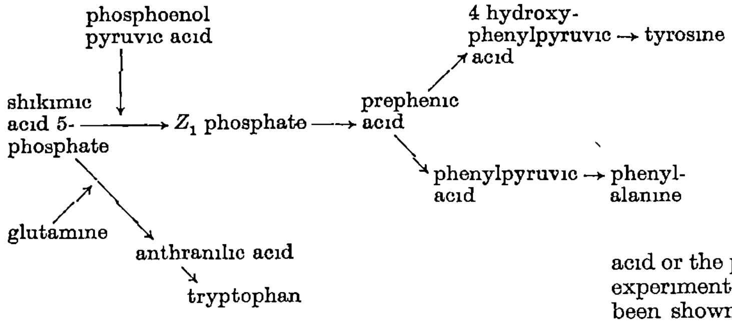
THE BRANCH POINT IN THE BIOSYNTHESIS OF THE AROMATIC AMINO-ACIDS

By DR MARGARET I. GIBSON, DR F GIBSON, DR C. H DOY and PAULINE MORGAN

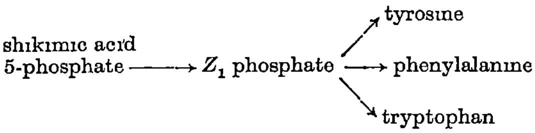
Bacteriology School, University of Melbourne

IT has recently been suggested by Sprinson[1] that 5-phospho-shikimic acid is a branch point in the biosynthesis of aromatic amino-acids (scheme 1), being metabolized on one hand through the compound 3-enolpyruvyl shikimic acid 5-phosphate (Z_1 phosphate), by the addition of phosphoenolpyruvic acid and thence through prephenic acid to phenylalanine and tyrosine Alternatively, nitrogen from glutamine is added to yield anthranilic acid

This scheme differs from that proposed by Davis[2] which is based essentially on the observation[3] that certain mutant strains of bacteria which required



Scheme 1 (after Sprinson, ref 1)



Scheme 2 (Davis, ref 2)

phenylalanine, tyrosine and tryptophan for growth accumulated 3-enolpyruvyl shikimic acid (compound Z_1) in their culture media

The recent observation that phosphoenolpyruvic acid stimulates the synthesis of both anthranilic acid and the phenylpyruvic acids from shikimic acid[4] is better in accord with the scheme advanced by Davis

The problem of the branch point has now been further examined It has been found possible to separate the conversion of shikimic acid to anthranilic acid or to the phenylpyruvic acids into two stages Cell extracts of *Aerobacter aerogenes* incubated with shikimic acid plus adenosine triphosphate (or shikimic acid 5-phosphate), magnesium and phosphoenolpyruvic acid (PEP) in *tris* buffer, form a compound with the same properties as had that assumed by Levin and Sprinson[5] to be Z_1 phosphate From the reaction mixture containing this compound either anthranilic acid or the phenylpyruvic acids can be formed under suitable conditions using mutants such as *A aerogenes* poly 3 blocked in the conversion of shikimic acid 5-phosphate to Z_1 phosphate These mutants are unable to form anthranilic acid or the phenylpyruvic acids from shikimic acid 5-phosphate An experiment in which anthranilic acid is produced in two stages is illustrated in Fig 1 This shows the rate of formation of precursor in the first stage as measured by the amount of anthranilic acid formed in the second stage Phenylpyruvic acids may be formed by the omission of glutamine in the second stage but the yields are relatively low owing to the presence of enzymes which destroy the acids

Treatment of the reaction mixture after the first stage with alkaline phosphatase followed by acid treatment yields a substance supporting the growth of a mutant strain of *Escherichia coli* which responds to shikimic acid Neither treatment alone produces a growth factor, but either destroys the substrate for anthranilic acid formation This substrate also disappears, as does the substance assaying as Z_1 phosphate, during prolonged incubation of the first stage The yield of anthranilic acid from the substrate formed is improved by the addition of potassium fluoride This is consistent with the observation[5] that fluoride inhibits the breakdown of Z_1 phosphate to Z_1, which would also be the product, already shown to be inactive as a substrate, of alkaline phosphatase treatment

The precursor which appears to be Z_1 phosphate was at first made by crude extracts or ammonium sulphate precipitated protein fractions of tryptophan auxotrophs, using as substrates shikimic acid 5-phosphate, magnesium and PEP in the absence of added diphosphopyridine nucleotide (DPN), its reduced form (DPNH) or glutamine The omissions prevent formation of anthranilic acid or the phenylpyruvic acids in the first stage of the experiment The *A aerogenes* mutant *A*170–44 has been shown[3] to accumulate compound Z_1 in culture media Extracts of this mutant fail to form anthranilic acid or the phenylpyruvic acids, but will do so when mixed with an extract of *A aerogenes* poly 3 In the presence of potassium fluoride, mutant *A*170–44 has also been shown to produce the substrate required by mutant poly 3 in a two-stage experiment

These observations suggest that the branch point is beyond shikimic acid 5-phosphate Scheme 3 represents our present concept of reactions around the branch point

The evidence for this scheme is as follows

(1) There is strong presumptive evidence that the same substrate, having the properties of Z_1 phosphate, serves as a precursor both for anthranilic acid and for the phenylpyruvic acids

(2) An extract of a mutant unable to convert shikimic acid 5-phosphate to Z_1 phosphate fails to form either anthranilic acid or the phenylpyruvic acids from shikimic acid 5-phosphate, as does an extract of a mutant accumulating Z_1 By mixing the two extracts it is possible to form these aromatic compounds

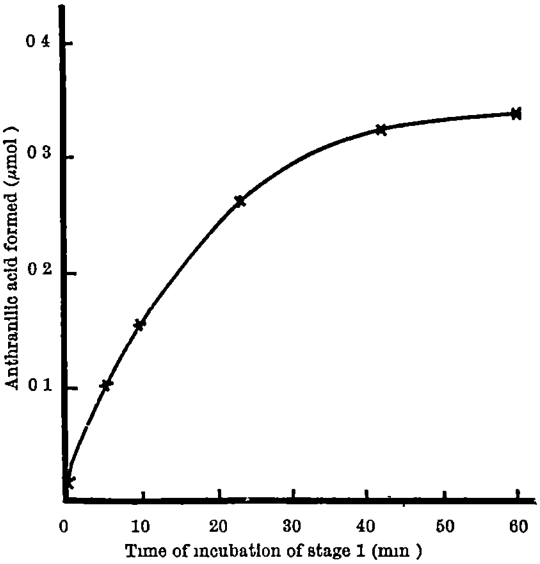


Fig 1 Production of anthranilic acid in a two-stage experiment Stage 1 Added per ml *tris* buffer *p*H 8 2, 100 μmol, $MgCl_2$ 10 μmol , ATP 2 μmol , shikimic acid 2 μmol , PEP 2 μmol , KF 20 μmol , *NC*$_3$ crude extract, 4 mgm protein Incubated at 37° C 0 5 ml samples taken at times shown and heated 5 min in boiling water bath
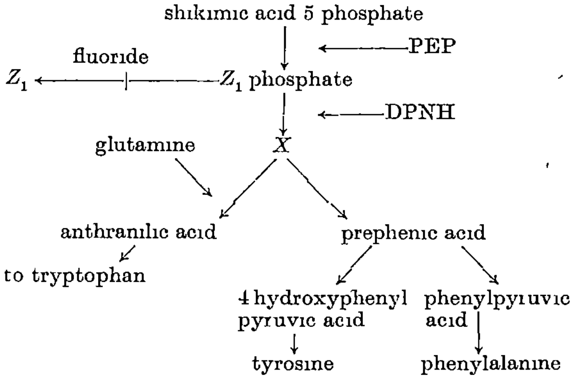
Stage 2 To each heated sample the following were added in 0 5 ml ribose 5-PO_4 2 5 μmol , glutamine 5 μmol , DPNH 1 μmol , poly 3 crude extract 2 7 mgm protein Incubated 45 min at 37° Tests acidified with 0 1 ml of *N* HCl and extracted with 4 ml ethyl acetate Anthranilic acid measured by optical density at 336 mμ
Strain *NC*$_3$ is a tryptophan auxotroph of *A aerogenes* responding to anthranilic acid Strain poly 3 is a 'polyaromatic' auxotroph of *A aerogenes* unable to form Z_1 phosphate from shikimic acid 5-phosphate



Scheme 3

(3) DPNH is not required for Z_1 phosphate formation, but is required for both anthranilic acid and phenylpyruvic acid formation

(4) Most mutants accumulating Z_1 require for growth tryptophan, phenylalanine, and tyrosine[3]

The existence of mutants which accumulate Z_1 and require for growth phenylalanine, tyrosine, tryptophan, 4-aminobenzoic acid and 4-hydroxybenzoic acid[3] suggests that the common pathway extends beyond Z_1 phosphate Evidence that in yeast shikimic acid 5-phosphate is the branch point for 4-aminobenzoic acid[6,7] was based on the observation that compound Z_1 did not serve as a substrate for 4-aminobenzoic acid synthesis As already seen, Z_1 phosphate rather than Z_1 is required for the formation of anthranilic and the phenylpyruvic acids and may also be the true intermediate in the formation of 4-aminobenzoic acid and 4-hydroxybenzoic acid

This work was supported by grants from the U S Public Health Service (*A*4632) and the National Health and Medical Research Council of Australia We thank Dr D B Sprinson for a culture of *Aerobacter aerogenes* 170–44

Note added in proof While this paper was in the press it was reported (Rivera, A, and Srinivasan P R, *Proc U S Nat Acad Sci*, 48, 864, 1962) that Z_1 phosphate can be converted to anthranilic acid in the presence of a DPNH generating system These observations support the general scheme advanced in the present article

IMMUNE OPSONINS IN *SCHISTOSOMA* INFESTATIONS

By Dr J. NEWSOME

Medical Research Council Bilharzia Research Unit, St Albans

SOME experimental schistosomicides stimulate an intense phagocytic reaction to schistosomes in the liver[1] During a trial of active compounds related to lucanthone[2] we believed that potentiation of drug action may have occurred, a very heavy *Schistosoma mansoni* infection (50,000 cercariæ) was cured in a baboon which had received thirteen previous infections but a similar infection was not cured in an animal infected only twice before The contrast between the two baboons at post-mortem was very striking This kind of drug potentiation has also been described in malaria[3], only trivial doses of antimalarials are needed for permanent cure of falciparum and malarial infections in hyperendemic countries When we began to examine the effects of antimony and lucanthone on *S mansoni* in whole blood and in media containing serum and white blood cells, it seemed advisable to repeat some of the experiments with blood from infected subjects in case immunological reactions should potentiate the drug effects

Accordingly, adult flukes were incubated in blood media from baboons infected five times in seven years, with and without small amounts of antimony or lucanthone, they were all rapidly attacked by leucocytes and killed within a day in the centre of large masses of white cells The drugs did no more than speed up the early stages of this lethal phagocytic response, in normal blood their effect had been slow, and a small amount of leucocytic sheathing only appeared after three days when the flukes were moribund The effect of immune blood was clearly much greater than that of the drugs, and this article describes some of the characteristics of the phagocytic reaction

Adhesion of leucocytes to parasites was first described in detail early in this century, Laveran and Mesnil[4] gave a full account, with fine illustrations of the opsonizing effect of antitrypanosome sera in 1901 They worked with *Trypanosoma lewisi* and were able to watch the attachment of leucocytes to trypanosomes removed from the peritoneal cavity followed by 'englobement' and phagocytosis The active cells in these preparations from the peritoneum were monocytes Mesnil and Brimont[5] in 1909 mentioned this reaction again and pointed out that immune serum by itself had no effect on trypanosomes They urged that the protective effect of antitrypanosome immunity must be due to the opsonin and depend on phagocytosis In 1927, Davis and Brown[6] described their work with *T equiperdum* They found that immune sera made many things adhere to trypanosomes leucocytes and leptospira sometimes became attached, but platelets were always attracted The platelet adhesion factor, first described by Rieckenberg[7] in 1917, was heat-stable and did not depend on complement There is a considerable literature on phagocytosis of malaria parasites by immune hosts[8] A paper by Zuckerman[9] refers to this literature and suggests that the controlling factor in acquired immunity to malaria is likely to be the production of opsonins which stimulate phagocytosis Zuckerman demonstrated phagocytosis of avian malaria parasites by agranulocytes in immune serum The opsonin was heat-stable, rendered normal and malaria-infected red cells sticky and stimulated agranulocytes from immune or normal animals Its activity was greatly reduced if the preparations were kept in motion

The most interesting parallel to the phagocytic reaction is that to microfilariæ of *Wuchereria bancrofti*[10] Tests were run on four types of sera from (1) patients with active elephantiasis, (2) patients with circulating microfilariæ but no clinical disease, (3) patients with a history of filariasis but no circulating microfilariæ, (4) normal people and patients with leucocytosis as controls A suspension of microfilariæ and red and white cells from *bancrofti* patients was added to these sera Within 12 hr , large numbers of leucocytes became attached to the microfilariæ, sheathed them and soon killed them in the sera from elephantiasis patients but not in the other classes of sera Figs 1–4 show clearly the equivalent of a 2 + antischistosome phagocytic reaction, as described here It was believed that the presence of this heat-stable antibody only in elephantiasis patients explained why such patients very seldom have microfilariæ in their blood A positive test was not obtained with any sera from patients with circulating microfilariæ It is interesting to remember that the prompt action of the microfilaricidal drug diethylcarbamazine is thought to be due to an opsonizing effect which causes the microfilariæ to be held up and destroyed by phagocytes in the liver[11]

The usual sterile precautions were taken when carrying out the phagocytic reaction test Blood was defibrinated in a conical flask containing glass beads and either filled into 6 × ¾ in test tubes or centrifuged at 3,000 r p m for 15 min to obtain serum and buffy coat For routine use 2 5 or 5 ml of the following media were set up in the 6 × ¾ in tubes whole blood, serum with buffy coat, and equal parts of serum and Tyrode's solution with buffy coat Streptomycin and penicillin, 100 units of each per ml , and glucose, 2 or 4 mgm /ml , were added A micromethod also gave satisfactory results 1 or 2 ml of blood was drawn into a 5-ml syringe containing glass beads and the needle occluded by pushing it into a small rubber bung The blood was defibrinated in the syringe by shaking The needle was changed and the blood delivered into a 11 × 0 5 cm glass tube, capped at both ends After centrifuging, most of the red cells were removed with a syringe and fine needle through the cap, leaving serum and buffy coat Antibiotics, glucose and Tyrode's solution were then added Adult *S mansoni* flukes were taken from the portal veins of hamsters into Tyrode's solution and introduced into the tubes, which were incubated upright at 37° C

Special reaction tubes in which the media were dialysed against serum were used in some experiments Cellulose sacs were attached to one end of 6 × ¾ in glass tubes by rings of silicone rubber which also served to close the 3 × 1 in rinsing tubes in which the dialysis sacs were suspended The rinsing tubes, filled with 18 ml of reconstituted dried human serum or fresh baboon serum containing glucose and antibiotics and stored in the refrigerator, were changed daily in a bacteriological hood

In the reaction tubes the flukes settled at the interface between cells and serum and could be seen with a lens For examination under a dissecting microscope, they were twitched up on to the tube wall by a rolling movement. The ensheathed flukes of a positive phagocytic reaction were preserved, either on the tube wall or at the interface, by removing the serum and replacing with formol saline. Paraffin sections and fresh smears were stained with Giemsa's stain and hæmatoxylin and eosin

The degree of leucocytic adhesion and lethal action was scored by one to four plus signs as follows

+	Flukes a little slow, some with small collections of white blood cells or very thin partial coating, often rather loosely adherent
+ +	Most flukes affected, movements and peristalsis slow, definite white blood cell collections round head and/or tail, or thin overall or thicker partial sheathing which made them stick to the tube wall
+ + +	Little movement, thicker complete or partial sheaths firmly attached, all flukes with some white blood cell coating, most appearing twice the normal thickness and sticking to the tube wall
+ + + +	Unmistakable large irregular masses of white blood cells with flukes in the centre, all affected and movement rare, but slow cæcal peristalsis occasionally present

The stages of a good 4+ positive test in serum with buffy coat medium were

Up to 2 hr the flukes were much slowed and cæcal peristalsis and sucker movement was reduced

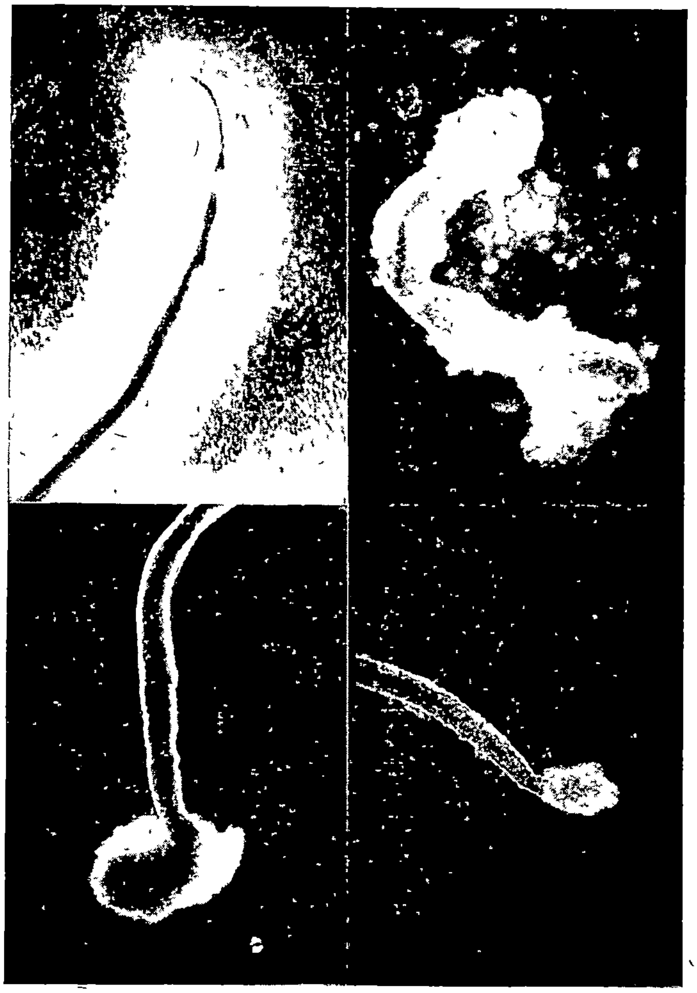
2–6 hr collections of leucocytes were firmly attached at head and tail and a coating of leucocytes, about as wide as the breadth of the fluke, slowly covered the whole surface, the flukes were barely moving

15–18 hr each fluke was in the centre of a large mass of leucocytes, but slight movement and weak peristaltic movement of cæcal pigment were sometimes seen

24–36 hr the flukes were dead and opaque, with clotted cæcal pigment, and the leucocyte masses round them had increased in size and sometimes contained pigment

The stages of weaker reactions took longer to appear, a final reading of 1+ did not usually occur until the third day and was considered doubtful unless repeated, the 2+ and 3+ results were evident by the second day Routine readings were made at approximately 18, 24, 40 and 64 hr and the quickest reaction was seen in the serum with buffy coat medium, followed by that in serum and Tyrode's solution with buffy coat medium and in whole blood Control preparations in normal blood supported flukes for 4–6 days, in normal serum with buffy coat medium for 8 days and in normal serum and Tyrode's solution with buffy coat medium for a fortnight Small collections of leucocytes and occasional thin loose overall sheathing were sometimes seen on dying flukes in normal media damaged by handling or by drugs

The influence on the phagocytic reaction of anæsthetics, antibiotics, heparin, additional glucose and the metabolic products of the blood cells was investigated Anæsthetics good positive reactions in media from unanæsthetized animals were not altered by giving the animals normal doses of ether, nembutal or phencyclidine, chance heavy dosage of these anæsthetics, however, sometimes reduced the adhesion of leucocytes Antibiotics the phagocytic reaction was the same whether streptomycin and penicillin (100 or 200 units per ml) were added to the



Figs 1–4 Leucocyte sheaths round adult *S mansoni* flukes (1) Fresh specimen showing large sheath round female fluke, (2) fixed specimen of male with 3+ reaction, (3) and (4) fixed specimens of small terminal sheaths on females with a 2+ reaction

media or not Heparin it was thought at first that good reactions often occurred when the hamster supplying flukes had been heparinized Comparison of heparinized and unheparinized flukes in a strongly positive serum with buffy coat preparation showed that heparin in trace amounts did not affect leucocytic attraction Glucose the initial glucose concentration in the media was brought up to well over 400 mgm per cent, but when glucose was omitted a good phagocytic reaction was still obtained, although sometimes it was less intense Metabolic products of blood cells whole blood, after 3 days' incubation, contained no glucose, 37 mgm per cent of urea, 200–230 mgm per cent of potassium and had a *p*H of 6 94 Flukes lived in these abnormal conditions for 4–6 days The speed and degree of the phagocytic reaction were, naturally, often less in blood than in serum with buffy coat and serum and Tyrode's solution with buffy coat media. However, the metabolic products of cells cannot have made much difference to the reactions, which remained the same in immune media kept reasonably healthy by dialysis against daily changes of serum In dialysed media made from normal blood, flukes lived for a fortnight, remained paired and laid eggs, some of which matured and hatched lively miracidia This was the first time that eggs laid *in vitro* had matured[12], and the dialysed media were clearly better than any yet used If, however, the cells were kept in motion by rolling the dialysis tubes, the phagocytic reaction in immune whole blood was reduced or prevented

Phagocytosis was first seen in blood from six adult *Papio hamadryas* baboons repeatedly and heavily infected with *S mansoni* The phagocytic reaction was stronger in two animals which had received four or five yearly infections of 1–4,000 cercariæ, weaker reactions being produced by animals infected two or three times. In addition, three animals infected once with 500–2,000 cercariæ 1½ years before examination gave no reaction

It was then found that uninfected baboons injected with fresh whole fluke material emulsified in complete Freund's adjuvant gave a strong phagocytic reaction Two animals were given 200 male and 200 female flukes on two occasions a week apart, and two received 120 of each sex at the first injection and 220 at a second injection a week later A 4+ phagocytic reaction was recorded 12 days after the second injection and, five months later, it was still graded as a good 3+

Nine adult monkeys (*Macaca mulatta*), belonging to Dr R Smithers at the National Institute for Medical Research, were also tested Media from an uninfected monkey and from one infected with 1,000 cercariæ of *S mansoni* 8 weeks before testing were negative. The infection dies out in rhesus monkeys within a year and they become resistant to re-infection, two such animals were examined twice at 15 and 16 months after 2,000 cercariæ, when they were no longer passing eggs One was negative and one gave a weak 1+ phagocytic reaction on both occasions

The remaining five uninfected monkeys all received an injection of fresh schistosome material with complete adjuvant and were challenged by an infection of 1,500 cercariæ. The phagocytic reaction was checked twice, at 5½ and 8 weeks after challenge, with the same results (Table 1) The adult *S mansoni* material always gave a positive phagocytic reaction Intramuscular injection was more effective than intradermal, and the best reaction was produced by monkey No 22 which received adult and egg antigens intramuscularly The cercarial antigens gave negative results and it may be supposed that adjuvant alone would also be inactive

Table 1 PHAGOCYTIC REACTION IN RHESUS MONKEYS INOCULATED WITH FRESH FLUKE MATERIAL AND ADJUVANT BY THE INTRADERMAL AND INTRAMUSCULAR ROUTES

Monkey No	Antigen	Route of injection	Phagocytic reaction
25	Cercariæ	I D and I M	−ve
12	Adult flukes	I D	++
24	Adult flukes	I M	+++
13	Adults and eggs	I D	+++
22	Adults and eggs	I M	++++

The test has only been performed in man on 18 patients, 6 with *hæmatobium* and 12 with *mansoni* infections As no *S hæmatobium* flukes were available, media from five of the *hæmatobium* patients were set up with *S bovis*, only two patients gave weak positive reactions (1+ and 2+) All five were adult males with histories of chronic infection The sixth *hæmatobium* patient, who had a long history and active disease, was tested with *S hæmatobium* flukes, but there was no reaction The clinical condition of the twelve *mansoni* patients varied from symptomless infection to severe diarrhœa with hepatomegaly Ten of them were negative One youth, with diarrhœa and numerous eggs in the stools, gave a 3+ reaction during a course of treatment, three other patients with less-acute infections received the same treatment but their phagocytic reactions were negative Of two more patients in an acute phase, one was negative and the other only gave a weak but definite 1+ reaction It was impossible to see any connexion between clinical condition and the ability to produce a positive phagocytic reaction

It had been hoped that repeatedly infected small animals which were highly resistant hosts for *S mansoni* might give positive phagocytic reactions in less time than the 3–5 years apparently required for immunizing baboons Cavies and rabbits, however, remained negative, and the later results with rhesus monkeys, the infections of which had died out naturally, confirmed that infection of naturally resistant species was unlikely to stimulate the phagocytic reaction

Because of the observation that *S bovis* flukes were sometimes attacked by leucocytes in human *hæmatobium* blood, it seemed that the phagocytic reaction might not be species-specific The effects of serum with buffy coat and serum and Tyrode's solution with buffy coat from two baboons, immunized with *S mansoni* material, on adult *S mansoni*, *S hæmatobium* and *S japonicum* flukes, were compared No difference in the degree or speed of leucocytic sheathing between the three species could be seen It is likely that *S bovis* flukes, had they been available, would also have been rapidly killed The test was performed in serum with Tyrode's solution with buffy coat medium on eggs, miracidia, cercariæ and a preparation of 20-day-old schistosomulæ which contained all sizes of pigment-containing larvæ The cercarial envelope test was positive but leucocytes were not attracted to cercariæ or to eggs Miracidia vanished from the preparation within 24 hr and were thought to be attacked by leucocytes Schistosomulæ of all sizes were killed and ensheathed by 18 hr but in normal blood they lived for 5 days

The serology of the reaction has not yet been fully investigated, but there is some preliminary information When immune and normal baboon sera were crossed with thoroughly washed cells from immunized and normal baboons, a positive phagocytic reaction appeared only in preparations containing antiserum Normal serum and 'immune' cells were inactive, except in some early experiments when the 'immune' cells had only been briefly washed and the residual antiserum allowed a weak reaction Removal of protein from antiserum by graded heating prevented the phagocytic reaction Inactivation of antiserum by heating at 56° C for 30 min did not prevent the reaction but usually reduced it by 1+ The addition of complement (neat cavy serum) to inactivated baboon antiserum did not improve the phagocytic reaction but prevented it Dilution of the mixture of sera with Tyrode's solution restored the phagocytic reaction The results with media containing dilutions of the two sera and well-washed 'immune' cells are shown in Table 2 The phagocytic reaction did not occur in inactivated serum diluted with more than three parts of Tyrode's solution and it was far from completely dependent on complement Flukes could not be made attractive to leucocytes by incubating them for 48 hr in strongly positive serum and, after a brief rinse, introducing them into normal serum with buffy coat, there was no sign of any phagocytic reaction after 3 days

Table 2 PHAGOCYTIC REACTION IN IMMUNE BABOON SERUM WITH CAVY SERUM DILUTION WITH TYRODE'S SOLUTION

Time (hr)	Cavy serum diluted times	Inactivated pooled immune serum diluted times			
		2	4	8	16
	2	0	0	0	0
18	4	±	0	0	0
	8	+	+	0	0
	2	0	+	0	0
28	4	+ + +	+ +	0	0
	8	+	+	±	
	2	0	0	0	0
40	4	+ + +	+	0	0
	8	0	0	0	0

The histology of the ensheathed flukes was examined fresh and in paraffin sections stained with hæmatoxylin and eosin The sheaths consisted of leucocytes in approximately the same proportions as in the buffy coat, the majority of the cells were neutrophil polymorphs and there was no evidence of differential attraction of any one type of cell Some neutrophils and monocytes entered the fluke tissues and the fluke cuticle was ragged in places It seems that the flukes died before the phagocytes had been able to inflict much cellular damage The leucocytes were examined fresh at 37° C and the majority remained alive and moved normally up to 72 hr

The phagocytic response of white cells from immunized primates to schistosomes *in vitro* has, so far as we know at present, these characteristics It appears in baboons repeatedly infected at yearly intervals with *S mansoni*, but it is weak after two infections and absent in baboons and rhesus monkeys after one infection It is absent in infected resistant hosts, such as cavies, rabbits and rhesus monkeys, the infections of which have died out It appears in baboons and rhesus monkeys within 20 days after injection of fresh fluke material with complete adjuvant, the most effective antigen is made from adult flukes with eggs It is rare and weak in man (but this is based on only 18 patients) In vaccinated baboons the phagocytic reaction lasts for 6 months and probably much longer It is not species-specific; all three human schistosomes are sheathed by leucocytes and killed in media from baboons immunized with *S mansoni* material It does not occur with cercariæ or eggs, is improved with miracidia, but is positive with all stages from the equivalent of 8-day larva to adult

A strong positive phagocytic reaction greatly weakens the flukes within 2 hr, before leucocytes can be seen to adhere to the cuticle The earliest collections of cells are commonly at head and tail, and in weak reactions these are often the only sites affected (Figs 3 and 4) Very large leucocytic sheaths can appear within 24 hr and all flukes die in 20–40 hr Movement of blood cells, for example, when the preparations are rolled, reduces the number of leucocytes that can gain attachment and an excess of moving red cells, as in whole blood media, can prevent the phagocytic reaction The reaction is not affected by anæsthetics, antibiotics, traces of heparin, additional glucose, high potassium concentration and metabolites of blood cells present in the preparations, it occurs when these abnormal substances are removed by continuous dialysis against serum

The attraction of leucocytes to the flukes depends on a serum fraction which is stable at 56° C but is precipitated with serum proteins at 85° C The fraction probably has no need of complement for its activity and it does not react with the fluke to make the cuticle attractive to leucocytes It remains active to a dilution of 1 in 4 and will produce a positive phagocytic reaction when added to leucocytes from normal uninfected hosts The phagocytic reaction system greatly potentiates the *in vitro* action of drugs A concentration of 0 1 mgm per cent of trivalent antimony (as potassium antimony tartrate) in media from uninfected subjects takes 3 days to kill *S mansoni* flukes, but in media with a strong positive phagocytic reaction, flukes die in less than 24 hr

The experiments performed under the good conditions prevailing in media dialysed against serum and rolled showed that the phagocytic reaction will only appear in almost stationary blood, fast-moving red cells prevent leucocytes from attaching firmly to the flukes, even in blood with a 4+ reaction The less the movement and the fewer the red cells, the quicker was the leucocytic sheathing[9] This suggests that hosts with a strong positive phagocytic reaction are unlikely to be protected against a new schistosome infection, but are in a good state of readiness to kill any adult flukes which, from old age, bad judgment, drug action, malnutrition or other deleterious changes in the *milieu* provided by their host, let go their hold on peripheral veins and are swept into the liver or lungs Here, as in the livers of rodents treated with diphenoxyalkanes[1], the flukes can block vessels and produce ideal conditions for rapid leucocytic sheathing

It is possible that the variable results of standard courses of antischistosome treatment in man reflect different degrees of phagocytic reaction activity as well as different rates of drug detoxication and excretion If so, frequently re-infected adults would show more positive phagocytic reactions and be easier to treat than children It is a common clinical observation, usually ascribed to efficient drug excretion by young healthy kidneys, that children can resist treatment which cures adults As the phagocytic reaction can be produced in a week or so by vaccination with whole-worm material, purified antigen may one day be given to uncured patients, with the object of alerting the reticulo-endothelial system ready for a second course of treatment a week later Before thinking of any practical applications, however, much more needs to be known Fractionation of the antigens and of the antibody globulins may give clues to the source of the antigen and the type of globulin that contains the antibody Other adjuvants less toxic than Freund's complete preparation must be used The lethal effect has to be investigated, it may be due to inability to absorb foodstuffs through cuticle and pharynx or to increased permeability of the cuticle to toxic antibodies With this new information the phagocytic reaction can be compared with the phagocytic systems described in filariasis and in other diseases due to helminths and protozoa which have contact with the blood

All the information we have at the moment suggests that immunity in parasite diseases is seldom mediated by antibodies which directly kill the parasite It seems more likely that the parasite's normal defences against immediate phagocytic attack are weakened and finally overcome Recent experiments, however, have not shown any protective effect of the phagocytic reaction system against challenge infection in monkeys The possibility of potentiation of drug action by the phagocytic reaction antibodies is under investigation

I thank Dr Janet Niven, Dr J H Humphrey and Dr R Smithers, of the National Institute for Medical Research, Mill Hill for their co-operation in these investigations

KINETICS OF MITOCHONDRIAL SWELLING: EVIDENCE FOR SPECIFIC RECEPTOR SITES FOR INDUCER COMPOUNDS

By HANS H GOSCH*, PROF JOSEPH C ARCOS and MARY F ARGUS

Department of Medicine, Tulane University School of Medicine, New Orleans

A VARIETY of organic compounds and inorganic ions are known to induce the swelling reaction of isolated mitochondria, a phenomenon that has been related to variables such as the level of adenosine triphosphate (ATP)[1,2], the coupling of oxidation to phosphorylation[3], the oxido-reductive state of the respiratory carrier[4], and the presence of oxidizable substrates[5] Previously, investigations on the swelling of mitochondria from the livers of rats administered hepatic carcinogens indicated[6,7] the existence of receptor sites for the inducer compounds (cf ref 8) It has now been found that the kinetics of induced mitochondrial swelling follows the Michaelis–Menten equation providing direct evidence for the existence of these sites

Male Sprague–Dawley rats, fed *ad lib* a dextrose–casein base semi-synthetic diet[7], called hereafter the basal diet, were used The rats which were administered 3′-methyl-4-dimethylaminoazobenzene (3′-Me-DAB) received the hepatic carcinogen incorporated in the basal diet at the level of 0·06 per cent for 4 weeks. The initial weight-range of all the rats was 180–220 gm. Isolation of the liver mitochondria and the swelling tests (by the photometric method, at 23°–25° C) were carried out as previously described[6,7], and the values of percentage swelling at 40 min were used. Phosphate (as disodium hydrogen phosphate), calcium chloride and *p*-chloromercuribenzoate (PCMB) were assayed in 0·15 *M* potassium chloride, buffered with 0·02 *M* *tris*-hydroxy-aminomethane, at *p*H 7·4. Thyroxine and diphosphopyridine nucleotide (DPN), however, were tested in identically buffered 0·30 *M* sucrose since these inducers failed to give consistent results in the potassium chloride system. Extensive preliminary testing over a wide concentration-range was required with each inducer to establish the experimental concentration-range (8–11 points) showing typical Michaelis–Menten kinetics when plotted in the direct manner. The amount of mitochondria isolated from a single liver was sufficient for swelling tests covering the whole experimental range plus a control in the respective system without added inducer. The experiments with each inducer were carried out on ten non-pooled livers. The control values were subtracted from the experimentals and the net percentage swelling values averaged.

* Recipient of a Student Research Stipend from the Tulane Educational Fund

The swelling reaction velocities versus the inducer concentrations were plotted in the double reciprocal manner according to Lineweaver and Burk[9] for calculation of the Michaelis–Menten K_m values and the extrapolated maximum velocities V_{max} (Fig. 1 and Table 1). The best fit of each curve was determined by the method of least squares. The correlation coefficients calculated for all double reciprocal plots are given in Table 1. This latter statistical treatment indicated that for PCMB (on basal diet and on 3′-Me-DAB) and for DPN the experimental values fit two lines with different slopes much better than one line, the two lines intersecting at the transition concentration S_{trans}. Accordingly for these two inducers two K_m and two extrapolated V_{max} values have been calculated. Similar kinetics was observed with phosphate and mitochondria from 3′-Me-DAB-fed rats, showing on the double reciprocal plot zero increase of the swelling reaction velocity at concentrations below 2·4 × 10^{-5} *M*. This inducer with normal mitochondria gave a plot fitting one line throughout the whole experimental range. The data obtained with mercuric chloride, also assayed in this investigation, are not included in Table 1 as this inducer gave considerable scattering of values with both test systems (K_m = 3·1 × 10^{-6} *M* to 7·1 × 10^{-5} *M*). Experiments now being carried out indicate that the swelling reaction of isolated rat heart sarcosomes induced by DPN, PCMB and pentachlorophenol also follow the Michaelis–Menten equation.

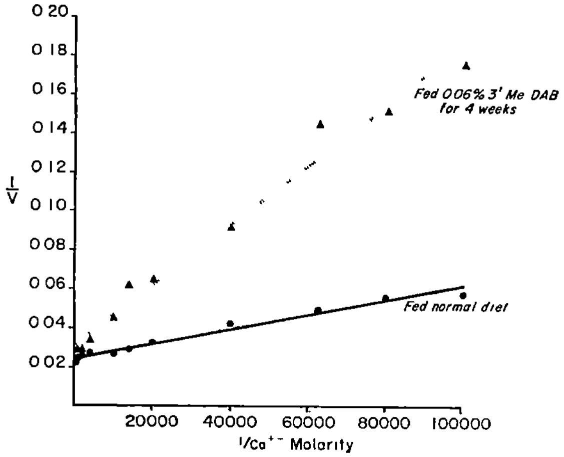

Fig. 1. Double reciprocal plots showing the effect of increasing inducer concentration (calcium chloride) on the velocity of the swelling reaction of isolated liver mitochondria

Table 1. Kinetic Values of the Swelling of Rat Liver Mitochondria Induced by Different Agents

	Inducer	K_m (*M*)	V^*_{max} (per cent)	S_{trans} (*M*)	Exp. range (*M*)	Correlation coefficient
Fed basal diet	$CaCl_2$	1·5 × 10^{-5}	40·0	—	1·0 × 10^{-5} to 5·0 × 10^{-3}	0·99
	PO_4^{3-}	6·5 × 10^{-5}	37·0	—	1·0 × 10^{-5} to 4·0 × 10^{-4}	0·92

	Thyroxine	3·3 × 10^{-6}	52·7	—	2·0 × 10^{-6} to 3·0 × 10^{-5}	0·98
	DPN	2·7 × 10^{-2} (6·4 × 10^{-3})†	54·1 (145·0)†	3·8 × 10^{-3}	3·4 × 10^{-3} to 5·0 × 10^{-3}	0·99 (0·99)†
Fed 3′-Me-DAB	$CaCl_2$	5·2 × 10^{-5}	32·3	—	1·0 × 10^{-5} to 1·0 × 10^{-3}	0·91
	PO_4^{3-}	4·1 × 10^{-5}	9·5	—	1·0 × 10^{-5} to 4·0 × 10^{-4}	0·76
	PCMB	7·8 × 10^{-5} (1·3 × 10^{-4})†	18·5 (143·0)†	2·0 × 10^{-5}	1·5 × 10^{-5} to 7·0 × 10^{-5}	0·97 (0·99)†

* Calculated V_{max} as percentage swelling. † Higher concentrations.

The present results provide strong support for the hypothesis[6–8] that the various agents that induce the ATP-reversible swelling[2] of mitochondria act in the particulate membrane[10,11] on specific loci which are receptor sites in the pharmacological or enzyme kinetic sense. That the relative affinities of the inducers to the receptor sites are estimated from the final extent of terminal effector action (that is, swelling) versus inducer concentration has the advantage that it excludes the obscuring of the kinetics by the rates of membrane penetration (possibly responsible for the initial lag period observed in the time-curve of certain types of swelling) and by non-specific adsorption, which may well be the case when determining the total fixation of inducers in the particles.

During the feeding of various hepatic carcinogens to rats the swelling ability of the liver mitochondria undergoes drastic alterations[6,7] which correlate with the time of appearance of gross tumours[6]. With 3′-Me-DAB the onset of irreversibility of these alterations is at about 4 weeks under similar dietary conditions as used in the present investigation[6]. The double reciprocal plots obtained with calcium chloride, phosphate and PCMB, following feeding of this dye for 4 weeks, show displacement of the curves akin to a non-competitive inhibition (for example, Fig. 1) resulting in decrease of the calculated V_{max} and no or relatively small change in the K_m values (Table 1). Since the initial amounts of mitochondria used in these tests were maintained strictly constant, the data are consistent with the decrease of the amount of receptor sites per particle due to feeding of the dye. Hence, further evidence is provided for the thesis[6,7] that one aspect of the azo carcinogen-induced cellular alterations may be the 'micro-denaturation' of control sites of the mitochondrial membrane. This is in agreement with other results from this laboratory that various water-soluble carcinogens are powerful agents of protein denaturation[12] A detailed report of the results here presented and of related investigations now in progress will be published at a later date together with further statistical analysis.

We thank Mrs Joyce B Mathison for her assistance in carrying out the determinations with DPN and mercuric chloride These investigations were supported by the U S Public Health Service research grant *CA* 05431

NEW SEROLOGICAL TEST FOR ALLERGY IN MAN

By Prof WALTER B. SHELLEY

Department of Dermatology, University of Pennsylvania, Philadelphia

PREVIOUSLY we have demonstrated that immediate allergic hypersensitivity can be detected in both patients and sensitized animals by means of the basophil leucocyte degranulation response[1,2] The test consists in exposing fresh heparinized blood to a given antigen for 15 min *in vitro*[3] Concentration of the basophils is achieved by liquid fixation and filtration, and is followed by specific toluidine blue staining for examination of the degree of degranulation During the past two years, practical experience with this test in many clinical conditions has revealed it to be an accurate and sensitive one Significantly, it was found that in acute allergic states the basophil undergoes degranulation not only *in vitro* but also *in vivo* Thus, the concept of the critical role of the basophil in immediate hypersensitivity reactions was confirmed, but the usefulness of the diagnostic test was dimmed at times for lack of basophils to observe

This article describes a new laboratory method which requires of the patient only serum Basophils as well as the antigen are supplied by the laboratory Such an indirect technique considerably expands the usefulness of the basophil degranulation response Simple enough for the smallest laboratory, it nevertheless lends itself to large central laboratory mass testing of diverse antigens on specimens of serum from patients at any distance No longer must the patient present himself to the laboratory for testing within minutes after the blood is drawn The serum may now be repeatedly tested any time or in any laboratory As many as 200 tests may be conducted on 1 ml of serum Furthermore, the test procedure is considerably shortened and simplified Finally, the donor basophil permits accurate readings on patients who have few or no circulating basophils

Venous blood is drawn from the patient into a sterile vacutainer, allowed to clot, and the serum separated for storage in deep freeze (–4° C) The serum may be used fresh or after repeated thawings, but plasma is not routinely satisfactory

Simple aqueous (0 9 per cent sodium chloride solution) dilutions of pure antigens, for example potassium salt of penicillin G or soluble extracts of complex antigens, for example, pollens, are used These may be prepared in the local laboratory or are available commercially as used in intradermal skin tests (Hollister-Stier Laboratories, Yeadon, Pennsylvania) The degree of reaction will vary with the concentration of the antigen used In the case of penicillin, screening tests have been made with an initial test antigen concentration of 1/100 (w/v). The sensitivity titre has then been ascertained by serial dilution of this antigen Positive reactions are rare at a concentration less than 1/10,000, but note that the effective final concentration is far less than this due to the dilution in performing the test The antigen concentration must not be so high as to induce basophil changes by itself as shown in the antigen control test The penicillin antigens are stored frozen, whereas most of the commercial antigens are simply kept in the refrigerator Precautions are taken to prevent bacterial contamination

Antigens not soluble in saline or buffer solutions may be dissolved in alcohol, ether or acetone, placed on the test slide, allowed to dry, and then used.

Although the donor basophils may be from a normal healthy human subject, we have found that for routine work the greatest number of test basophils are to be secured from rabbit blood. Using albino New Zealand rabbits, 1 ml heparinized blood is freshly drawn from the lateral ear vein Keeping it chilled in the refrigerator such blood maintains a physiologically and anatomically satisfactory basophil for about 2 h For each test, a drop of blood is introduced into a 7-cm length of transparent polyethylene tubing (Clay–Adams *P E* No 90, 0 86 mm internal diameter, end, heat sealed), through a long No 22 needle on the end of a tuberculin syringe If capillary blood is desired, an open polyethylene tube may be filled with a drop of blood from the finger-tip and the end then heat sealed by match flame and hæmostat The tubing is placed in a 2-mm glass tubing for support and spun in a micro-hæmatocrit centrifuge (for example, 30 sec, 11,500 rev/min) The resultant buffy coat is isolated by clamping and cutting with a razor blade The micro-drop of buffy coat is then ready for immediate addition to the serum on the specially prepared slides

Flame clean microscope slides, cool until only slightly warm, flood with freshly prepared stain rapidly, and avoid overlaying. Drain excess stain back into bottle and air-dry Stain should not be applied before an open window, or in hot, humid atmosphere, 5 ml of staining solution are adequate for 75-100 slides The slides may be stored indefin-

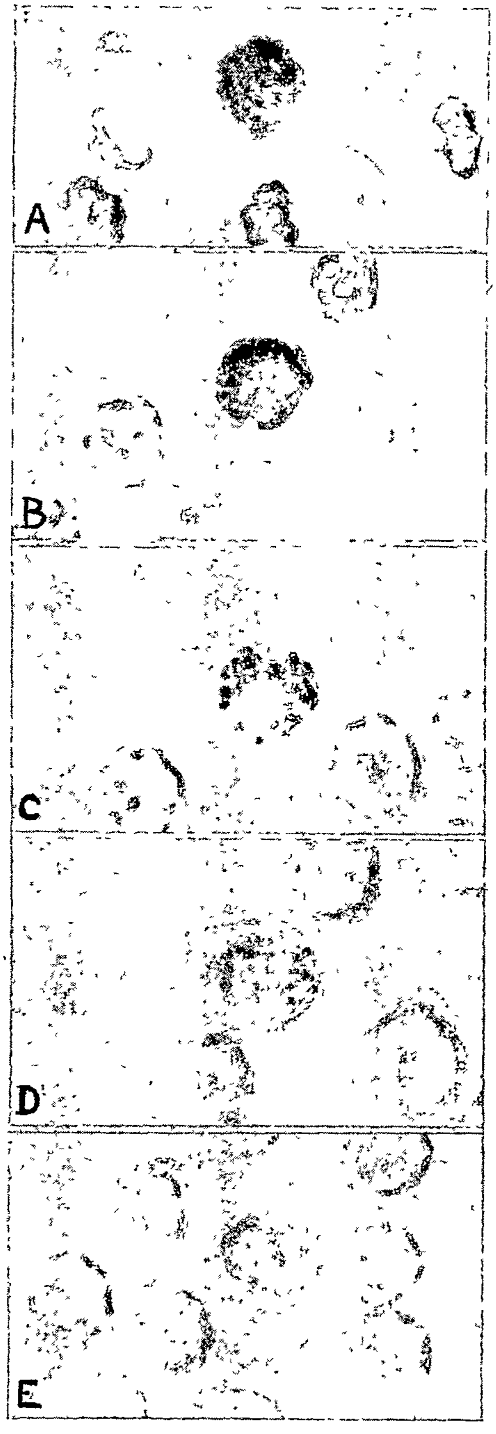

Fig 1 Views of progressive specific allergic degranulation of a single living donor basophil in presence of grass pollen extract (0 001 mgm N) and serum of hay fever patient Time *A*, 0, *B*, 5 min, *C*, 8 min, *D*, 10 min, *E*, 17 min Supra-vital stain Room temperature

itely in a dust-proof container Stain formula to 5 ml of absolute ethyl alcohol, add 0 6 ml of the neutral red stock solution (0 3 per cent in absolute ethyl alcohol)

Neutral red, as a *p*H indicator dye, rapidly points up the acidic nature of the basophil granules Toluidine blue staining of the heparin has also been used by us supra-vitally with success

Add 0 005 ml of patient's serum to stained slide using a micropipette or a micro-drop from 27 needle on tuberculin syringe Add entire buffy coat by blowing out of cut segment Add 0 005 ml of antigen solution Mix by gentle air agitation and cover with 'Vaseline'-edged cover-slip (No 1) Readings are made under oil by scanning the living field Within 5 min the basophil granules stain a distinctive brick red The cell can be sharply distinguished from all other leucocytes After 5 min read the first 20 basophils for changes in shape, stainability and degranulation Immediate readings can routinely be done within 10 min Slow reactions may be observed by later readings at 20–30 min Antigen controls consisting of test antigen and rabbit basophils as well as serum controls consisting of test serum and rabbit basophils must be done regularly

In the positive test the majority of the basophils show a loss of sphericity, cell distortion, swelling, granulolysis, granular swelling, less staining, rapid oscillation or dancing of granules, loss of granules. appearance of clear nucleus, cell wall bleb formation. and streaming of granules from the cells Explosive degranulation is seen in the more sensitive individuals We have found that the living cell permits more accurate assessment of its functional state than does the dead fixed cell, so that typing is not regularly necessary Observation of the behaviour of a single cell is not adequate since occasional cells in the control may undergo degranulation

Should the antigen control show degranulation, it is necessary to decrease the concentration In the event of the rare positive serum control, new serum should be secured Occasional patients may be sensitive to the traces of rabbit serum present in the buffy coat We have not seen anyone sensitive to the neutral red

This indirect technique has been successfully used in the study of many patients with immediate hypersensitivity states Among these were 22 men who had had penicillin reactions Fourteen of these gave a positive test Significantly, none of 10 control patients at present receiving penicillin treatment without incident gave any evidence of basophil degranulation The penicillin-sensitive patients regularly showed a positive test to aminopenicillanic acid as well as certain cross-sensitivity reactions to the new synthetic penicillins In six patients with atopic dermatitis, five showed specific degranulation reactions to chocolate, three to milk. three to tree pollens, and one each to grass pollens. wool and wheat In control tests with 30 different rabbits and 100 sera, but one positive reaction was seen and this in a patient with known serum hypersensitivity

By means of supra-vital staining, the allergic degranulation process has been observed and photographed for the first time in a single basophil Fig 1 shows such a progressive reaction It is apparent that without awareness of the sequence, few would identify Figs 1*D* and *E* as a basophil leucocyte This test is based on the rapid passive sensitization of donor basophils *in vitro* Hence, it may be successfully employed with other methods of observing degranulation such as the buffy coat smear technique[4]

Our experiences with this indirect basophil test in food, drug and insect bite reactors (both urticarial and anaphylactic) and atopic dermatitis patients, as well as those with serum sickness, asthma hay fever, contact dermatitis and ulcerative colitis have revealed an expanding vista of clinical usefulness for the basophil In our laboratory it has been a safe, reliable and sensitive indicator of serum antibodies not otherwise always evident It affords an assay of the allergic potential of new drugs, and other problems of cross-sensitization It aids in the diagnosis of obscure, as well as common, allergic states Furthermore, the therapist is given a method of objectively measuring changes in sensitivity during programmes of hyposensitization As noted above, potential anaphylactic reactors may be identified Nevertheless, the test remains an index only of the patient's status at the time the blood is drawn It cannot predict which patients will develop allergy, for example, to penicillin, or indeed which patients have temporarily depleted their antibody and thus are incapable of reacting at the time of blood sampling Finally, this technique has proved itself in work on sensitized animals as well as on man

CHEMICAL EFFECTS OF MECHANICAL DISPERSION OF ALKALINE CHLORIDE

By Dr HENRY M. PAPÉE and Dr GIANNA L PETRICONI

Centre for Aerosol Nucleation, National Research Council of Italy

ELECTRICAL effects due to deformation of sodium chloride crystals are well known[1,2], and it has been shown that mechanically induced stress can lead to defects in alkali halides[3] It has been shown, on the other hand, that while thermal evaporation of sodium chloride results in chemically uncontaminated particles, considerable amounts of nitrate and colloidal sodium impurities appear on the surface of the salt when a dry sodium chloride smoke is electrostatically precipitated by means of excessively large voltages[4] It has to be emphasized that while formation of NO_3^- impurities readily occurs through the action of NO_2 gas on moist sodium chloride particles[5], the same appears to happen in a dry air carrier medium and in electrical discharges[4]

Alkaline chloride samples of reagent grade were ground using a mechanical, heated, agate mortar, and sieved to − 270 mesh by means of mechanical vibrator The product was then separated into monodisperse fractions by use of a Bahco centrifuge (Éts Neu Co , Lille) The rotor of the instrument was heated during centrifuging to about 100° C by means of an electrical tape which was wound round the shield of the centrifuge, and hot air was blown over the orifice of the instrument during its operation This was done to prevent caking and agglomeration of particles on exposure to air moisture at room temperature According to the stage of the preparation, samples were stored either in a stove at 150° C, or in a desiccator in an atmosphere of pure, dry nitrogen Since the size of the particles obtained was too large to warrant nitrogen Brunauer–Emmett–Teller surface determination, the dimensions of the granules were estimated microscopically by an optical micrometer attachment Fig 1 shows photomicrographs of the monodisperse samples obtained

If it is assumed that electric or triboelectric[6] phenomena induced chlorine vacancies on the surface of alkaline chlorides during grinding, then it follows that the relative increment of sodium per unit surface will be approximately proportional to the increase of surface area during the process Thus

$$\frac{d\,\Delta OH^-}{S} = K\,dS \qquad (1)$$

where ΔOH^-, which is measured after solution of the halide sample, is the total excess over stoichiometry of sodium (situated in the outer strata of the solid) in the product Integration of equation (1) between zero and S surface values, yields

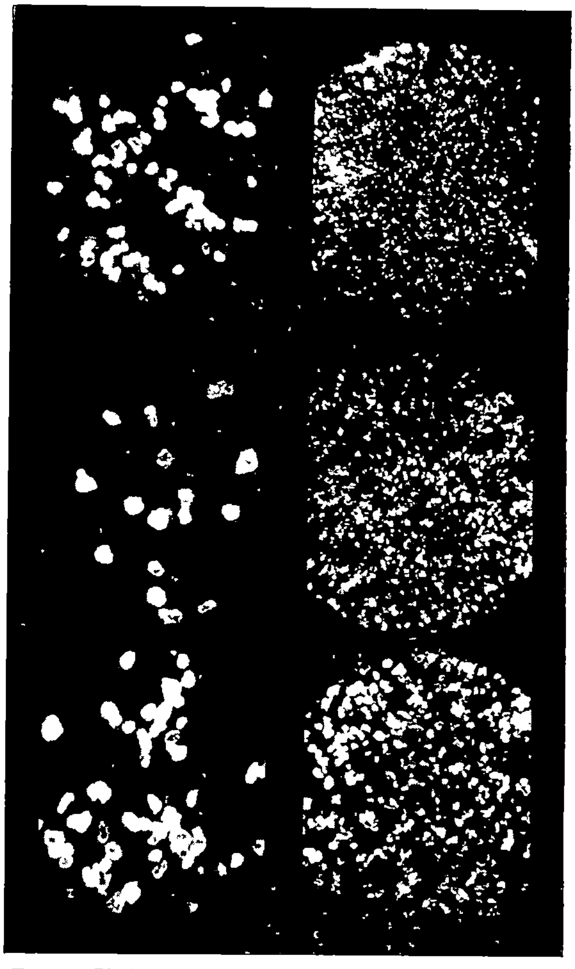

Fig 1 Photomicrographs of monodisperse sodium chloride particles used Visual field is 0 78 mm in diameter

$$\Delta OH^- = \tfrac{1}{2} K S^2 \qquad (1')$$

As expected, however, nitrate impurities were found in the samples after grinding, and although measurements of OH^- resulted in consistent trends according to equation (1), it was found that the behaviour of nitrates could not be fitted into a pattern such as given by equation (1). Surprisingly, however, vacuum outgassing of ground samples resulted in decreases of *p*H values of the product afterwards dissolved. This in turn led to the suspicion that triboelectrically generated nitrate, which is adsorbed on the surface, could be reduced to ammonia by the active centres on the surface in presence of very small amounts of moisture. Assuming this

$$\frac{dN}{dS} = K'S \qquad (2)$$

where N stands for the number of active centres created per unit surface.

Integrating

$$\int_0^N dN = K'\int_0^S S\,dS \qquad (2')$$

Therefore

$$N = \tfrac{1}{2}K' S^2 \qquad (2'')$$

and since it may be assumed that

$$NH_3 = K''\, N\, NO_3^- \qquad (3)$$

substitution of equation (2″) yields

$$NH_3 = K_3 S^2\, NO_3^- \qquad (4)$$

The alkalinity of the samples studied was determined using a sensitive *p*H meter, while nitrate and ammonia were measured colorimetrically by the brucin and Nessler reagent methods respectively. Triple-distilled water was used for the preparation of 100 ml. aliquots of solutions containing 300 mg reagent purity, ground, monodispersed salts, while 0.5-g aliquots were used for NH_4^+ determinations.

Fig. 2 gives plots of ΔOH^- against S^2, per unit weights of both sodium and potassium chlorides, while Fig. 3 gives corresponding plots according to equation (4).

The results indicate that mechanical fragmentation induces considerable changes in surfaces of alkali halide particles, and that therefore particles prepared in this way cannot be considered as pure halides from the point of view of their surface properties. It is possible that effects leading to a chemical change such as already described may be partly responsible for the power of ice nucleation shown by some freshly ground substances[7,8], it is furthermore possible that processes of repeated mechanical fragmentation, friction, and distortions induced by hydration and desiccation, which atmospheric aerosol undergoes, may to some extent contribute to the formation of atmospheric nitrate and ammonia largely contained by sodium chloride nuclei[9].

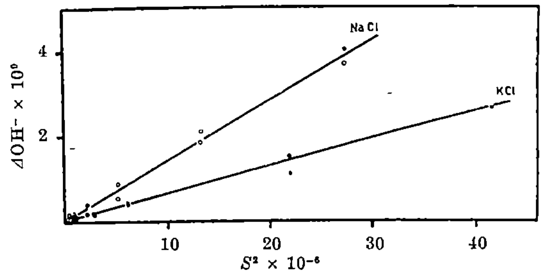

Fig. 2. Plot of the change of ΔOH^- (in g-equiv.) per gram of ground sodium and potassium chlorides, versus square of specific surface of monodispersed salt, separated by centrifuging (cm²)

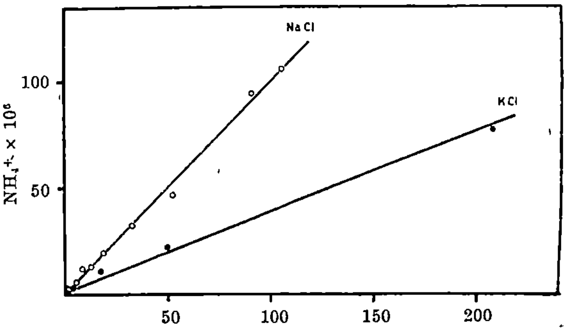

Fig. 3. Plot of the change of ammonium content (in g-equiv.) per unit weight of sodium and potassium chloride samples, against the square of specific surface (in square centimetres) of monodispersed salt obtained by grinding and centrifuging, multiplied by its content in nitrate (in g-equiv. per gram of salt)

We thank Prof. V. Caglioti for his interest and encouragement, and Mr. M. Armeni for the drawings and technical help.

THORIUM AND URANIUM CONTENTS OF AUSTRALITES

By R. D. CHERRY

Department of Physics, University of Cape Town, Rondebosch

THE thorium and uranium contents of six australites have been measured in this laboratory. The technique used was that of 'thick-source' alpha counting[1-3] combined with the thorium-*A* pairs method of Mayneord *et al.*[4] A scintillation counter was used as a detector, and the experimental apparatus was similar to that described by Turner *et al.*[5] A total alpha count-rate, C, and a 'pairs' rate, P, are measured. If one assumes radioactive equilibrium and a known uranium-238 to uranium-235 ratio, then C and P are related to the uranium and thorium concentrations U and Th by equations of the type

$$C = k_1\text{Th} + k_2\text{U} \tag{1}$$

and

$$P = k_3\text{Th} \tag{2}$$

The constants k_1, k_2 and k_3 depend on the decay constants and atomic weights of uranium-238, uranium-235 and thorium-232, the area of the sample and, finally, the ranges of the alpha-particles of the thorium, uranium and actinium series. The evaluation of these constants has been discussed in detail by me[6]; here it will suffice to point out that in practice C is about thirty times larger than P, and is accordingly subject to a much smaller percentage error in the counting statistics.

The australites used included two from Victoria (Nos. 1 and 4), two from South Australia (Nos. 355 and 475) and two from Western Australia (Nos. 379 and 1176). The samples were supplied by Dr. S. R. Taylor and Mrs. M. Kaye. They had all been ground to 120 mesh and had previously been analysed for alkali metals[7,8], trace elements[9,10] and major elements[10]. No chemistry was necessary, the samples were merely packed and sealed on 'Perspex' rings in the manner described by Turner *et al.*[5], allowed to stand for a month or more and then counted. The total counting time amounted to about seven days per sample.

The results are summarized in Table 1, which includes also the potassium determinations of Taylor and Sachs[7,8]. The percentage standard deviations in C and P due to counting statistics alone average 1·8 and 11 per cent respectively for each sample. If it is assumed that counting statistics are the only appreciable source of error, then it follows from the appropriate numerical insertions into equations (1) and (2) that the analytical precision of the determinations of thorium and uranium are about 11 and 13 per cent respectively. The following features are worthy of note.

(*a*) The absolute values of uranium and thorium for the 'mean' tektite from our group are 2·0 and 9·4 p.p.m. respectively. Because of uncertainties in the ranges of alpha-particles in solids[6] (and consequent difficulty in determining absolutely the constants k_1, k_2 and k_3) it is difficult to estimate the errors in these values. It is thought unlikely, however, that these errors exceed 10 per cent. The agreement with the single high-quality value of Tilton[11] for a South Australian australite (namely, uranium at 1·74 p.p.m. and thorium at 9·19 p.p.m.) is reasonably satisfactory. The thorium/uranium ratio for our samples averages out at 4·9, and is quite comparable with that obtained for common terrestrial material[15].

(*b*) A high positive correlation between the count-rate C and the potassium content (as determined by Taylor and Sachs[7,8]) is immediately apparent. Because of the relative inaccuracy of the individual pairs rate values, this same trend is not obvious in the values of P, thorium and uranium. It seems fairly certain that a positive correlation does in fact exist between the potassium content and the uranium and/or thorium values, since it would be very difficult to account for the sympathetic variation of C with the potassium content on any other basis. Such a positive correlation should be taken into account by any theory which postulates tektite origin on the basis of a mixing hypothesis such as the recently suggested hypotheses of quartz–shale[12] and chondrite–soil[13] mixtures. On the quartz–shale hypothesis, if one follows Taylor[10] and assumes that quartz has a negligible uranium and thorium content, then, of course, the positive correlation between potassium and uranium and/or thorium is explained since the potassium content is itself negatively correlated with the silica content[10,12,14]. Similarly, the chondrite–soil mixture will also explain the positive correlation, since the levels of potassium, uranium and thorium in chondrites[15] are very much lower than in tektites and soil.

(*c*) Perhaps the most striking feature of the results in Table 1 is the small spread in the uranium and thorium values over the six samples counted. The percentage standard deviation of the six uranium values is 17 per cent, while that of the six thorium values is 15 per cent. Since we have estimated the analytical precision at 13 per cent and 11 per cent for uranium and thorium respectively, it would appear that the inherent spread in the results for the six samples is about 11 per cent for the uranium content and about 10 per cent for the thorium content. These figures are probably upper limits, and it is interesting to note that the relative standard deviation of the six count-rates, C, is as low as 5 per cent.

Table 1

Tektite No.	P (pairs/h)	C (counts/h)	K content (per cent)	U content (p.p.m.)	Th content (p.p.m.)
1,176	0·70	17·4	2·12	1·4	11·6
379	0·50	16·7	2·03	2·4	8·4
4	0·58	16·8	1·88	2·1	9·7
1	0·63	15·7	1·73	1·8	10·6
355	0·49	15·7	1·73	2·2	8·3
475	0·48	15·2	1·73	2·1	8·1

Relative spreads for other elements in australites have been quoted by Taylor[10]. Many of those (notably silicon, potassium, iron, lithium and barium) are as low or lower than the above results for thorium and uranium. The implications of this low variance in tektite composition relative to terrestrial rocks have been discussed in detail by Lowman[16], who concludes that it is a weighty factor against theories which suggest that tektites are produced by a mechanism which results in the fusion of terrestrial materials. Anders[17] has pointed out that tektites might possibly have been derived from smaller areas than the six million square miles assumed in Lowman's study, and has suggested that rock analyses should be selected from a few small areas for legitimate comparison with tektite variances. A desirable experiment at the present junction would appear to be the following. The variance of selected elements (for example, potassium, lithium, thorium) in possible parent materials (for example, shale[12], soil[13]) should be studied as a function of the surface area from which the samples of 'parent material' are collected. If it is found impossible to produce variances as low as those found in tektites even by limiting sampling to small areas, Lowman's conclusion will have been substantiated. If, on the other hand, variances approximating to those occurring in tektites are found at a particular size of sampling area, then some information will have been obtained as to the likely areal magnitude of any event leading to the formation of tektites from terrestrial materials.

I thank Dr S R Taylor and Mrs Maureen Kaye for the provision of the australite samples and Prof L H Ahrens for discussion

STIMULATED ELECTRON SPIN-FLIP TRANSITION AS THE SOURCE OF 18-MEGACYCLE RADIATION ON JUPITER

By L LANDOVITZ
Yeshiva University

AND

LEONA MARSHALL
New York University

THE discovery of strong radio emission from the planet Jupiter was made in 1955 by Burke and Franklin[1] Since then a great deal has been learned about the characteristics of this radiation, but as yet no satisfactory explanation has been given[2–10,16] It is the purpose of this article to suggest a way in which the radiation may be produced which seems to account for most of the features peculiar to Jovian radio emission

First we summarize what is so far known about the radiations The average intensity of a burst of radiation is about 5×10^{-21} W m^{-2} $(cycle/sec)^{-1}$ The bursts are intermittent, and most of the energy is emitted in a narrow frequency-range extending from 10 to 35 Mc with a maximum intensity at 18 Mc and a half-width at half maximum of about 3 Mc In any given burst the energy is contained in an even narrower band width of about one-half Mc per sec This relatively monochromatic emission cannot be ascribed to black body radiation at any temperature

The rotational period of Jovian radio sources agrees with the accepted rotational period determined by observation of visible features on the surface of Jupiter The radio emission seems to come from a localized source having directional properties That is, the probability of emission of a burst is high during only about 1/6 of the Jovian day The probability of emission seems to show an inverse correlation with sunspot number It has been recognized that such a correlation would result from the existence of a Jovian ionosphere in that its increased ionization at sunspot maximum would make the escape of radiation from the lower levels of the ionosphere less probable

It is a peculiarity of the Jovian radio broadcasts that although they may be detected first at one frequency, they may be detected slightly later at either higher or lower frequencies The frequency of onset of these storms seems to drift to either higher or lower frequency with almost equal probability, and furthermore the drift in frequency toward the end of each of these broadcasts seems completely uncorrelated with the drift in frequency at the beginning The rate of frequency drift is a few Mc/sec The broadcasts last for about 3 sec on the average

The Jovian radio emission has been shown to be mainly right-hand circularly or elliptically polarized, an effect which suggests the existence of an intrinsic magnetic dipole field of Jupiter analogous to the Earth's magnetic field

Considerable evidence has accumulated which shows a correlation between solar coronal eruptions and Jovian radio emission 1–10 days later, indicating that the Jovian broadcasts are initiated by solar particles which travel from the Sun to Jupiter with travel times varying from 1 to 10 days Additional evidence for the correctness of this view is found in a correlation between solar flares and geomagnetic activity on one hand, and Jovian radio emission 8 days later, during a time when Jupiter and the Earth were aligned along the same radius from the Sun (in opposition) When Jupiter is no longer opposed to the Sun as seen from the Earth there is correlation between solar flares, geomagnetic storms, and Jovian noise storms delayed by 8 days plus the time required for the Sun to rotate through the heliocentric angle between the Earth and Jupiter, indicating that the same centre of activity on the Sun shoots out particles as it rotates, perturbing now the Earth, and now Jupiter

Various suggestions have been made about the origin of radio emission from Jupiter, none of them entirely satisfactory Lightning discharges in Jupiter's atmosphere would produce radiation at all wave-lengths, unpolarized, and unlikely to be strongly correlated to a fixed interval of longitude of the planet The mechanism of plasma oscillations should produce radiations over a broad band of frequencies, corresponding to a continuous decrease in ion density from high values deep in Jupiter's atmosphere to the low densities of interplanetary regions The mechanism of synchrotron radiation from solar particles spiralling in Jupiter's magnetic field would be expected to produce higher harmonics as well as the fundamental cyclotron frequency, because the solar particles must have velocities 0 01 c –0 1 c in order to reach Jupiter in 1–8 days All these mechanisms have the drawback that one expects from them radio emission over a much broader frequency range than 18 ± 3 Mc/sec

We suggest instead that this radio emission is a maser-like phenomenon, namely, is a decameter emission from electrons making spin-flip transitions in the perturbed magnetic field of Jupiter, and that furthermore the radio emission is stimulated as the perturbation travels through the ionosphere of Jupiter. We suggest that impinging clouds of solar particles stimulate perturbations which in turn cause very sudden changes (ΔH) in the local magnetic field of Jupiter, in the time of the Larmor precession, so that the local population of electrons initially having an equilibrium distribution of spin orientation with respect to the local field direction is suddenly stimulated to make spin-flip transitions. The incidence of a cloud of solar particles, therefore, subjects an electron population in a static magnetic field to an oscillating magnetic perturbation causing the electron population to emit radiation at the Larmor frequency characteristic of the static field[11].

It is reasonable to suppose that all atoms at low densities are ionized by sunlight. The atmosphere of Jupiter is thought to be largely hydrogen, consequently the exosphere contains mainly protons and electrons.

The characteristic frequency of the radio emission, 18 Mc, provides a determination of the local Jovian magnetic field of 6.4 gauss = H at the altitude where the emission occurs (according to $\nu_c = 2.8\ H$ Mc/gauss). The clouds of solar particles have average densities ~ 10^4 particles/cm^3, travel with velocities $v \sim 1 \times 10^8$ cm/sec, contain magnetic fields ~ 2×10^{-3} gauss, and have an average dimension $d \sim 2 \times 10^8$ cm (see, for example, ref. 12). The time of passage of such a cloud is given by $t \sim d/v = 2$ sec, in agreement with the duration time of radio emission.

Such high-velocity clouds of solar particles carrying magnetic fields are known to produce in the exosphere of the Earth sharp crested magnetic waves[13] of ~ ± 0.001 gauss amplitude, between 7 and 14 Earth radii. We assume that a similar coupling occurs when solar clouds impinge on the exosphere of Jupiter and that in fact magneto-acoustic waves[14] are produced in low-density plasma having high-frequency components (for example, ~ 10^7 c./sec) short wave-lengths, and magnetic amplitude ΔH ~ 2 milligauss. The local field in which the electrons find themselves is adiabatically changed from H to $H + \Delta H$ (where $\Delta H \sim 0.002$ gauss) in a time not large compared with the time of the Larmor precession, $t_L \sim 5 \times 10^{-8}$ sec. The rapid oscillations of magnetic field act as perturbations able to produce spin flip and radiation at the Larmor frequency.

The frequency at onset should drift to higher or lower frequencies depending on the path taken by the magneto-acoustic wave train in the exosphere. For example, if the wave-pocket travels toward the surface of Jupiter, the emitted Larmor frequency will drift to higher values corresponding to increased values of the local Jovian magnetic field.

An order of magnitude estimate of the spin-flip probability caused by a change of $\Delta H \sim 0.002$ gauss in $\Delta t \sim 2 \times 10^{-8}$ sec is given by[15]

$$|\alpha|^2 = \frac{\mu^2}{\hbar^2} [\Delta H]^2 [\Delta t]^2 = 16 \times 10^{-8}$$

where $\mu = eh/2\,m_e c$ is the electron magnetic moment. Suppose that an electron experiences q such changes per sec. Then the probability of spin flip per electron is $16q \times 10^{-8}$ per sec. Let N_e be the electron density, and assume that the radiation comes from a volume $V \sim R_J{}^3$ where R_J is the radius of Jupiter (which may be taken as an estimate of the thickness of a Van Allen belt on Jupiter). Then $V \simeq 3 \times 10^{29}$ cm^3. The number of electrons which contribute to the radio emission caused by the solar cloud is VN_e.

If the spin-flip radiation is produced isotropically, then the power P received on Earth is given, in units of energy per unit area per unit frequency interval, by

$$P = 16(h\nu_L)N_e V(q \times 10^{-8})/(D_J)^2(1/2 \times 10^6 \text{ c./sec})$$

where $D_J = 6 \times 10^{11}$ m is the distance between Earth and Jupiter, and where $1/2 \times 10^6$ c./sec represents the average band-width of a burst.

We find

$$P \simeq qN_e \times 10^{-33} \text{ W (m)}^{-2}(\text{c./sec})^{-1}$$

The average power is observed to be ~ 5×10^{-21} W (m)$^{-2}$ (c./sec)$^{-1}$. Then

$$qN_e \sim 1.5 \times 10^{12}$$

so that if $N_e \sim 10^7$ electrons/cm^3 (corresponding to the maximum density from which decametre radiation can escape), then q may be as small as 10^5 rapid changes in magnetic field per sec.

Actually one expects that the spin-flip radiation is not isotropic, but instead is emitted roughly parallel and anti-parallel to magnetic field lines on Jupiter. This feature is in agreement with the observed correlation of frequency of emission of 18 Mc/sec radiation with phase of the Jovian day, and may contribute an enhancement factor to the power of radiation received on Earth. (Note that the angular dependence of magnetic dipole radiation is $(1 + \cos^2\theta)d\Omega$ where θ is the angle between the propagation direction of the radiation and the magnetic field. Thus, the radiation tends to come out parallel and anti-parallel to the magnetic field lines of force. However, if there is a tipping of the magnetic axis with respect to the rotation axis, there will be a dependence of frequency of radio emission on phase of rotation, because of the displacement of geographic and magnetic poles, we are presented with portions of the field roughly parallel and perpendicular to the Earth's axis at different times of day.)

GEOPHYSICS

A Working Model illustrating Density of the Upper Air

In a previous communication[1] I proposed a preliminary model of the strong variability of the upper air density due to the extraterrestrial influence This model has now proved itself also for times of low solar activity at the beginning of the year 1962 At this time the solar radio noise at 10 7 cm had decreased to a value of 100 × 10^{-22} W /cm ^{2} cl Since the last sunspot maximum was extremely high, the solar activity was more strongly varied during 1958–62 than from a mean sunspot maximum to the minimum Four effects have been found predominant (1) the solar electromagnetic wave effect with its subdivision, (1*a*) solar short ultra-violet effect, (1*b*) day–night effect, (2) the corpuscle effect with, (2*a*) magnetic storm effect, and (2*b*) the plasma effect (solar wind) (annual and semi-annual effect)[2]

The plasma effect must cause an additional steady influx of heat from interplanetary matter besides the ultra-violet radiation as also other authors have recently concluded[3-5] The plasma effect was first found by me through its semi-annual and annual variation[6], which have now been independently confirmed[4]

With the expressions in ref 1, equations 1 and 2, the total completed formula for the air density $\rho(h)$ can be written now for low and mean latitudes as

$$\log \rho(h) = \log_{\text{stand}} \rho(h) - \Big[\iota(220, h)\Big(1 + \iota(\theta)\theta_t(h)\frac{220 - F}{F}\Big) + \theta_{\text{stand}}(h) f(\theta) + g(a, F)\, a(220, h) + K(200, h)\frac{A_P}{200}\Big] + \{\qquad\} \quad (1)$$

where F is intensity of the solar 10 7 cm. radio noise in units of 10^{-22} W /m ^{2} cl, θ is local time, a is month in the year, A_P is planetary magnetic index

The new functions $\iota(\theta)$ and $\theta_t(h)$ (Fig 1) give the dependence of the day–night effect on the solar activity The plasma-effect $g(a, F)\, a(220, h)$ markedly decreases with the solar activity according to equation (2), from which some conclusion can be gained about the dependence of the solar wind on the sunspot activity

$$g(a, F) = g(a) + (220-F)[0{\cdot}0060 - 0\ 0020 g(a)] \quad (2)$$

The dependence of the phase functions $g(a)$ and $f(\theta)$ on the month a in the year and local time θ has been already given in ref 1, Fig 1 The height functions $\iota(220, h)$ $a(220, h)$ and K (200, h) are given in Fig 2 up to an altitude of 1,500 km Table 1 represents the last values of the reference density profile $\rho_{\text{stand}}(h)$ In equation (1) terms of second order, which consider the dependence of the different terms on each other, have been neglected It has been found that these second-order terms are very small below an altitude of 1,000 km

Table 1 $\rho_{\text{stand}}(h)$

h (km)	gm /cm ^{3}	h (km)	gm /cm ^{3}
150	1 912 × 10^{-12}	600	1 623 × 10^{-15}
200	2 246 × 10^{-13}	700	7 418 × 10^{-16}
250	1 337	800	3 613
300	5 170 × 10^{-14}	900	1 782
350	2 445	1,000	8 765 × 10^{-17}
400	1 213	1,200	2 500
450	6 005 × 10^{-15}	1,400	8 600 × 10^{-18}
500	3 994	1,600	4 397

As a proof the theoretical accelerations were calculated from equations (1) and (2) The result is demonstrated for several satellites with different heights and day–night cycles for the perigee in Fig 3, where the value

$$\log\left[\frac{dP}{dt}_{\text{obs}} \Big/ \frac{dP}{dt}_{\text{calc}}\right]$$

is given for the monthly means

No systematic discrepancies can be seen The random scatter amounts to 10 per cent for *Explorer I* (1958 α), while the total amplitude of its acceleration goes up to the factor 10 For 1959 α the latter varies by the factor 50, while the single points in Fig 3 vary only by 20 per cent Since no more systematical residual variations exist in Fig 3, equation (1) must well represent all the major effects on the upper air density in low and mean latitude

Accepting this good agreement between calculation and observation, the density variations of the upper

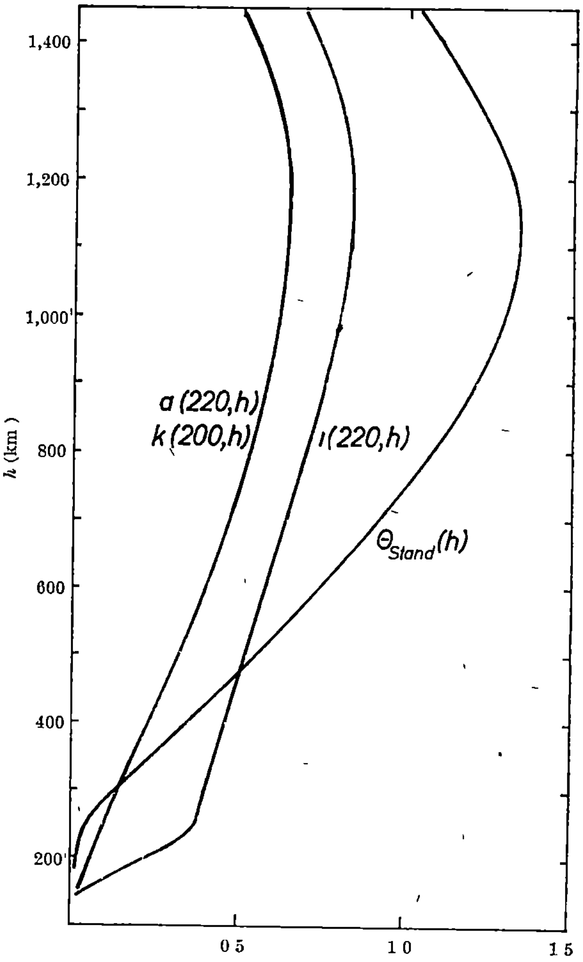

Fig 1 The functions $\iota(\theta)$ and $\theta_t(h)$

air can be described up to an altitude of about 1,000 km by a linear combination of several terms, which can be attributed to distinct physical processes The following conclusions can be drawn

(1) The upper air represents a much more reliable physical system than the lower Its physical state can be fairly predicted for the different parameters as solar and magnetic activity, the local time and the date in the year.

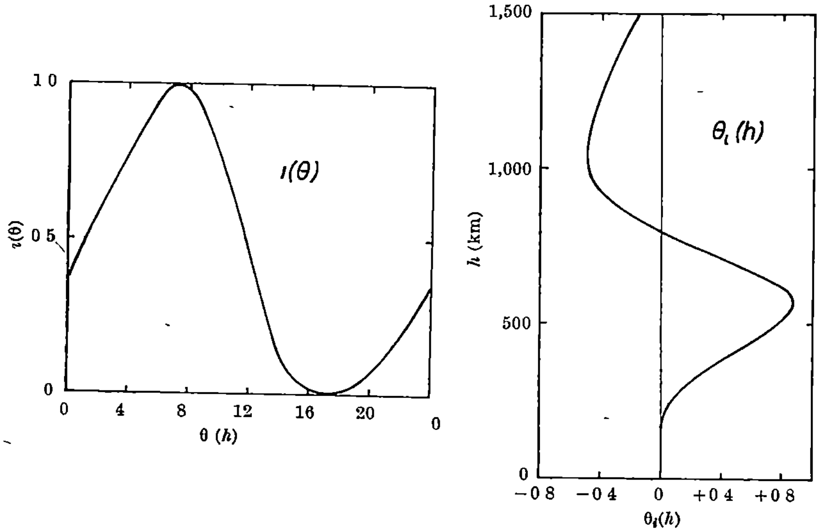

Fig 2 The height-functions $\iota(h)$, $a(h)$, $\theta_{\rm stand}(h)$ and $K(h)$

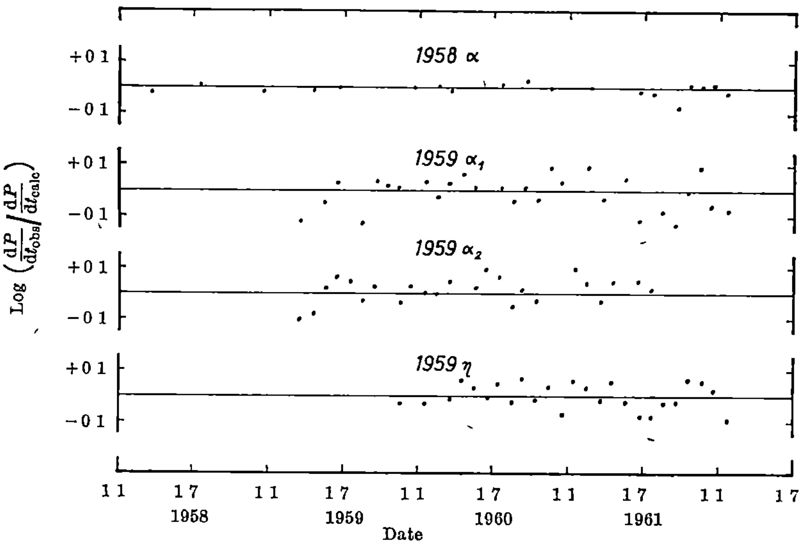

Fig 3 The comparison between calculated and observed satellite acceleration

(2) For geodetic satellites it seems possible to eliminate sufficiently second-order effects of atmospheric drag at least over longer periods

PHYSICS

Radioactivation Analysis of Niobium in Tantalum by Irradiation with Protons in a Cyclotron

Considerable work has been done in the past decade on the separation and determination of relatively small amounts of tantalum and niobium However, no adequate method for the determination of these elements seems to have been devised Although neutron activation analysis has provided a good tool for the determination of many elements, no satisfactory results have been obtained for niobium in tantalum The reasons are as follows (1) small cross-section for the ^{93}Nb(n, γ)-^{94m}Nb reaction (1 1 ± 0 1 barn), (2) ^{94m}Nb has a short half-life (6 6 min) and emits a weak γ-ray (0 0415 MeV), (3) chemical similarity of these elements

We have undertaken to determine a small amount of niobium in tantalum foil of a tantalum capacitor, using the ^{93}Nb(p,n)^{93m}Mo reaction As shown in Fig 1, the target consists of five tantalum foils (29 mm × 23 mm , 18 2 mgm /cm ^{2}) and two niobium foils (29 mm × 23 mm , 7 5 mgm /cm ^{2}) The two tantalum foils outside were used for target covers, and the tantalum foil of the centre used for the determination of niobium in tantalum The two niobium foils were used for radioactivation standard The target was set in a water-cooled holder, and irradiated with 14 5 MeV protons in the internal beam of a cyclotron (10 μamp , 10 min) Proton energy was chosen from the excitation function for the reaction ^{93}Nb(p,n)^{93m}Mo determined by R A James[1] Loss of proton energy in the foils was calculated with the use of the rate of energy loss of protons in silver (for niobium) and gold (for tantalum), and it was found that in this case loss of energy was negligible The surfaces of the irradiated foils did not show any change

The following chemical treatment was used for the separation of ^{93m}Mo from the irradiated foils Small portions (3 ml) of molybdenum solution (1 mgm /ml) were added to a platinum crucible as carrier, and carefully dried up on a water bath The irradiated foil was then fused in this crucible with potassium bisulphate (5 gm), and the melt kept at dull redness for 10 min The resulting cake was dissolved in boiling 15 per cent tartaric acid (100 ml) After a clear solution was obtained, it was rapidly cooled with ice water A fairly rapid stream of hydrogen sulphide was passed into this cold solution for 5 min ,

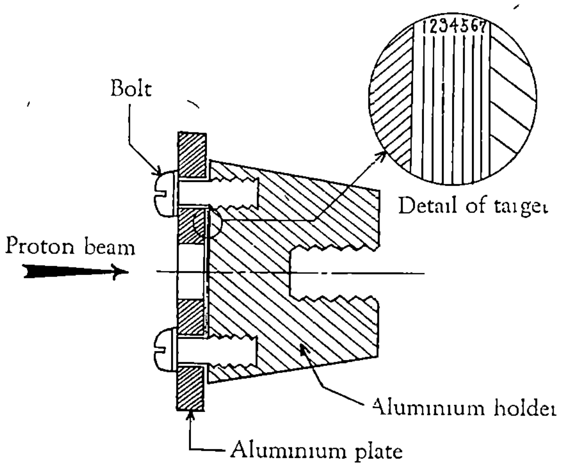

Fig. 1. Cross section of target and target holder. 1, 3, 4, 5, 7, tantalum foil; 2, 6, niobium foil

and then the solution was heated to boiling and kept near the boiling point for 5 min under continuous passage of hydrogen sulphide. After cooling the solution in ice water, the precipitation of molybdenum as sulphide was filtered off, washed, dried and radioactivity measured. This chemical process required less than 1.5 h, with a yield exceeding 80 per cent.

The total γ-ray activities of ^{93m}Mo were counted with a well-type sodium iodide (1.75 in. diam. × 2 in. high). Further, the ^{93m}Mo (0.263, 0.685 and 1.479 MeV) photopeaks were measured with an Argonne type 256 channel pulse height analyser with a large sodium iodide crystal (3 in. diam. × 3 in. high). The decay curve agreed with that of ^{93m}Mo. The niobium content in tantalum was estimated to be 0.2 per cent from the ^{93m}Mo activities of the two niobium foils. The contribution of the (Mo + p) reactions was negligible under our conditions.

This method appears to be a very sensitive one for the determination of niobium and is very effective for the analysis of niobium in tantalum. The determination of 10^{-1} p.p.m. niobium can be expected by this method.

We thank Mr. M. Furukawa for his valuable advice, and the crew of *Ins* (Tokyo) cyclotron for their assistance.

A Negative Ion Source using a Mercury Pool Cathode

Negative ion sources are now being used extensively in nuclear research. The demands from these sources are more rigorous than for their positive ion counterpart, and lives are around 100 h for hydrogen, much less for oxygen. Experiments in which the filament of the ion source has been replaced by a mercury cathode (Fig. 1) have given much larger currents (up to 700-amp pulse) and lives. With hydrogen beams, after 600 h operation the source showed only slight wear on the electrodes and indicated an indefinitely long life, while tests with oxygen and with sulphur beams, each for 300 h, indicated no difficulties. These tests were under conditions which gave magnetically analysed ion beams of H^-, 15 µamp, of O^-, 15 µamp, and of S^-, 8 µamp.

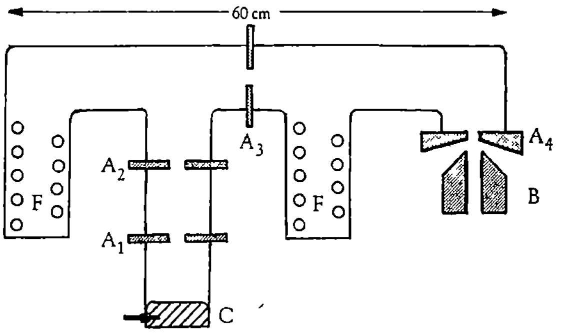

Fig. 1. A_1, A_2, A_3, auxiliary anodes; A_4, final anode; B, 40-kV ion extraction canal and electron donor target; C, mercury pool cathode; F, refrigerated coils

The mechanically refrigerated traps operate at − 50° C. A search was made for a mercury beam by running the ion source positive. None was found, which puts the upper limit in terms of the negative ion beam as less than 1 per cent.

GEOLOGY

The Highland Boundary Fault: Reverse or Wrench Fault?

Detailed work which I have done in the Loch Lomond area suggests a definite answer to the above problem which is of some importance since it concerns one of the major geological features of the British Isles. The direction in which the principal stress acted in the production of the fault can be approximately determined from the pattern of structures in the Lower Old Red Sandstone conglomerates, and this supports the contention put forward in stratigraphical accounts (summarized by J. G. C. Anderson[1]) that the Highland Boundary Fault is a reverse fault of Caledonian age and not a Proto-Armorican wrench fault as envisaged by E. M. Anderson[2].

Immediately south of the fault, the chief rock type is a conglomerate composed of rounded to ellipsoidal boulders of quartzite with subordinate vein quartz, porphyry, and andesite. The inequidimensional boulders have their major and intermediate axes parallel or slightly oblique to the planes of bedding, and in the upturned to vertical attitude of the bedding close to the fault had their maximum surface areas normal to the direction of principal stress during most of the deformation.

The compressive stresses in the vicinity of the fault during deformation were sufficient to rupture most of the pebbles in the conglomerate for some distance south of the fault as noted by du Toit[3]. The cracking is megascopically conspicuous and is independent of shape and size of the boulders. The fracture planes may be regularly spaced or form highly shattered narrow zones concentrated chiefly in the central area of the pebbles, and similarly orientated directions of cracking can be traced for many yards in adjacent boulders although the matrix is not visibly affected Where the pebbles are subordinate to a sandy matrix no cracking occurs

The patterns developed in individual pebbles may be conjugate fractures with an average angle of 20°–30°, one set of parallel cracks agreeing in orientation with the mean bisectrix of the conjugate set or a combination of both These patterns compare with the laboratory experiments on the compression of rock in the brittle régime[4] Under such compression rocks are brittle, and rupture is expressed in extension fractures parallel to the major stress direction associated with acute-angled wedge fractures

Numerous small shear zones with slickensided surfaces and wrench displacement are prominent in both conglomerate and sandstone horizons, and these have an orientation parallel or oblique to conspicuous trends of cracking The orientation of the shear zones falls into two sets the bisectrix of which approximates to the direction of single cracking in pebbles mentioned above The structures described are the product of the main stresses responsible for the fault and are not secondary structures resulting from the movements on the fault

The direction which corresponds to the maximum of single cracks and bisectrices of conjugate cracks and shear zones is therefore taken, by analogy with laboratory behaviour of similar brittle materials, to be the direction in which the principal stress acted This direction is north-west–south-east, almost at right angles to the trend of the Highland Boundary Fault

The investigation so far reveals a definite pattern to the tectonic structures in the Lower Old Red Sandstone commensurate with horizontal compression of the rocks in a north-west–south-east direction, as in a vice, thus confirming the reverse fault theory of origin

Post-Glacial Sea-Levels

FIG 1 compares eustatic data from New Zealand with a generalized eustatic curve calculated from raised strandlines in Sweden and Norway[1] The Fennoscandian region is undergoing isostatic rebound initiated by the retreat and melting of the Fennoscandian ice-cap, so that the Post-glacial raised strandlines owe their positions to the combination of two effects, changes in both land- and sea-level The basic assumption behind the calculated eustatic curve (Fig 1) is that the rates of isostatic rebound have been proportional from place to place—the raised strandlines used being from areas between Sauramo's Finniglacial and Gotiglacial hingelines[2,3]

Details of the calculations used by Dr H R Thompson, biometrician of the Applied Mathematics Laboratory, New Zealand Department of Scientific and Industrial Research, and of the data selected for the New Zealand curve, will be published shortly in the *N Z Journal of Geology and Geophysics* Note that some slight corrections have been made to that portion of the New Zealand curve younger than 4,000 years B P (compare with that given by Schofield[4,5])

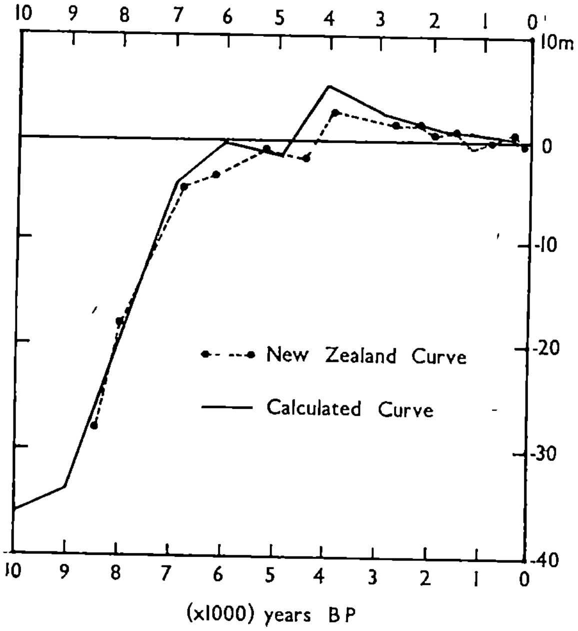

Fig 1

The calculated curve agrees with a Post-glacial high sea-level of about 4,000 years ago It is also similar to the curves of Godwin *et al* [6] and McFarlan[7] in that following the initial, rapid, Post-glacial rise, sea-level reached the present level 5–6,000 years ago Both the calculated and New Zealand curves parallel Fairbridge's[8] curve but differ in detail, the most important being the absence of his sea-level 'highs' of −15 m, 9,000 years ago and +3–4 m of 5–6,000 years B P

Isotopic Ages from Some Spitsbergen Rocks

ISOTOPIC ages by potassium – argon and rubidium – strontium methods have been measured on some Spitsbergen rocks, in the hope of contributing to the Mid-Palæozoic time-scale and to the understanding of local geological history[1] Rubidium strontium and argon measurements were made by stable isotope dilution analysis, except for York's figure, which was by total volume (argon) measurement The potassium measurements were made by flame photometer

The following specimens were analysed, and the results are given in Tables 1 and 2

Table 1 POTASSIUM – ARGON ANALYTICAL RESULTS

Sample	Volume of argon (mm^3 N T P) Wt of sample (gm)	K_2O (per cent)	Atmospheric contamination (per cent)	Apparent age (m y)

				378 ± 4

Analyst E Hamilton (Oxford)
(^{87}Rb $\lambda = 1.47 \times 10^{-11}\ yr^{-1}$)

Chydenius granite[2,3] *H* 686-9 This is a 'post-tectonic' porphyrite adamellite cutting and metamorphosing folded Hecla Hoek rocks The upper part of the succession contains Canadian (Ordovician) fossils This granite follows closely the main Caledonian (Ny Friesland) tectogenesis, but can only locally be shown to precede part of the Carboniferous where an apophysis of the batholith is truncated by rock, probably of Moscovian (Upper Carboniferous) age, and to the south-west probably of Tournaisian (Lower Carboniferous) age.

Hecla Hoek Schists[4,5] *H* 825-9, *E* 275-6, *E* 686 On the east shore of Raudfjorden, Red Bay conglomerates (L O R S) unconformably overlie Hecla Hoek schists 300 m above the base an Upper Downtonian (Upper Lower Gedinnian) fish fauna[6] is present The Red Bay conglomerates are unmetamorphosed and truncate mica schists, marbles and migmatites, which have been correlated with the Lower Hecla Hoek

The concordance of rubidium – strontium and potassium – argon ages would indicate an age of metamorphism of 383 ± 10 m y It was at this time that the Hecla Hoek mica schists were formed, and for the purpose of this communication it suffices to date this event Further work is being carried out using the isotope geochemistry of strontium to search for older ages So far, two older rubidium – strontium ages have been determined, and the possibility that older potassium – argon ages are preserved is being investigated

If 383 ± 10 m y is taken provisionally as the latest age of metamorphism of the schists, there would have to be considerable erosion and some deposition between this date and the base of the Upper Downtonian This suggests a date for the base of the Devonian (Downtonian) of 383 m y or less

The present status of the time-scale is summarized in Table 3 The generally accepted age for the base of the Devonian is 400 m y , but not all other ages dating this point in the time-scale are based on materials which are as well defined stratigraphically as the present ones Although it is not advisable to suggest a detailed revision of the time-scale based on one isolated area, the Spitsbergen ages would necessitate that the apparent length of the Devonian Period is reduced and that of the Silurian increased Leaving the other boundaries unchanged, this would give the Devonian and Silurian Periods durations of approximately 38 and 42 m y respectively, instead of 70 and 20 m y on Kulp's 1961 scale

Table 3 SUCCESSIVE MID-PALÆOZOIC TIME SCALES

To base of	Holmes (ref 7) 1960	Kulp (ref 8) 1960	Kulp (ref 9) 1961
Carboniferous	350 ± 10	350	345
Upper Devonian		365	(365)
Middle Devonian		380	390
Lower Devonian	400 ± 10	400	405
Silurian	425	430	425

The apparent ages given in this communication date a thermal event which may be regarded as marking the last phase of the 'Caledonian orogeny' in Spitsbergen The possibility that the absolute age may have been lowered by re-heating in Tertiary times is considered to be most unlikely The slightly older ages obtained for the Chydenius granite, and *E* 686 of the Hecla Hoek series, may indicate incomplete loss of argon or radiogenic strontium during the metamorphic event In addition, the rubidium – strontium ages have been calculated using an original ^{87}Sr/^{86}Sr of 0.712

In the time-scale compiled by Kulp[9], the Shap granite is given as Lower Devonian with an age of 395 ± 5 m y It would appear that this is an erroneous tabulation. The original data[10] from which this age was obtained gave

K-Ar — 391 ± 7 (weighted average of four determinations of 393 ± 12, 391 ± 20, 397 ± 12; 383 ± 12)

Rb–Sr — 381 ± 7 (weighted average of three determinations of 385 ± 11, 380 ± 19; 364 ± 24) The arithmetic mean of these two results indicates an apparent age of 386 m y which is in agreement with the Spitsbergen ages

We thank Prof L R Wager and Sir Edward Bullard for allowing us to investigate these rocks at Oxford and Cambridge, using the rubidium – strontium and potassium – argon methods, respectively

ENGINEERING

Ultrasonic Wave Velocities in Stressed Nickel Steel

EXISTING methods for detection of residual stresses in metals are limited to surface or near-surface examination, and will not reveal stresses within the material. A possible method of detection is the use of ultrasonic waves in a manner analogous to the use of light waves in photoelasticity. An ultrasonic shear (transverse) wave entering a stressed solid body splits up into two components travelling at different velocities depending on the relevant elastic 'constants' which are slightly different along the two principal stress axes normal to the wave propagation direction. This action is analogous to photoelasticity, where the two components of a polarized light wave are due to electrical anisotropy (variation of permittivity with direction) caused by the stress within a transparent body. Internal stress, including residual stress in metallic bodies, might therefore be detected by observation of the phase shift between the two ultrasonic waves occurring in what has been called 'sonoelasticity'.

Preliminary to work on the practical application of 'sonoelasticity' to the detection of residual stresses, measurements have been made of the variations in velocity with applied stress of three types of ultrasonic wave in nickel steel. These measurements have yielded values of the second-order or Murnaghan elastic constants[1], very few of which have been found by other workers. They are difficult to evaluate directly with any accuracy, since this involves measurements of a small non-linearity in the relation between stress and strain, and the strain itself is small in metallic materials. Ultrasonic velocity variations with stress are also very small, but can be measured accurately by electronic techniques. In the present work, measurements have been made of the changes in velocity of a 2·5 Mc/s longitudinal and two 4·5 Mc/s shear waves generated by quartz crystals and propagated across the centre of a nickel steel bar under compressive stress acting along the axis of the bar. The two shear waves were polarized, one parallel to and the other normal to the stress axis. Changes in velocity were made by measuring both the changes in transit time of the waves and the changes in path-length related to the longitudinal strain by Poisson's ratio. The changes in transit time were measured by the 'sing-around' method[2], whereby a selected echo from the pulse transmitted into the bar was used to trigger the transmitter again, the pulse of energy thereafter 'singing-around' the system at a repetition rate (pulse repetition frequency) determined by the total effective ultrasonic transit time. The pulse repetition frequency was measured by a counter-type frequency meter.

Table 1. LAMÉ AND MURNAGHAN CONSTANTS (in BARS × 10^5)

Material	λ	μ	l	m	n	Source
Polystyrene	0·2889	0·1381	−1·89	−1·33	−1·00	H. and K
Armco iron	11·00	8·20	−34·8	−103·0	+110	H. and K.
Pyrex	1·353	2·75	+1·4	+9·2	+42	H. and K.
Nickel steel	9·09	7·80	−4·6	−59·0	−73·0	D.I.C.

H. and K., Hughes and Kelly; D.I.C., present work.

The measurements made to date are shown in Fig. 1, where it may be seen that, within the limits of measuring precision, there is a linear relationship between stress and 'sing-around' pulse repetition frequency for each of the three wave types. The relations between the three velocities and stress are given by the following equations derived by Hughes and Kelly[3]:

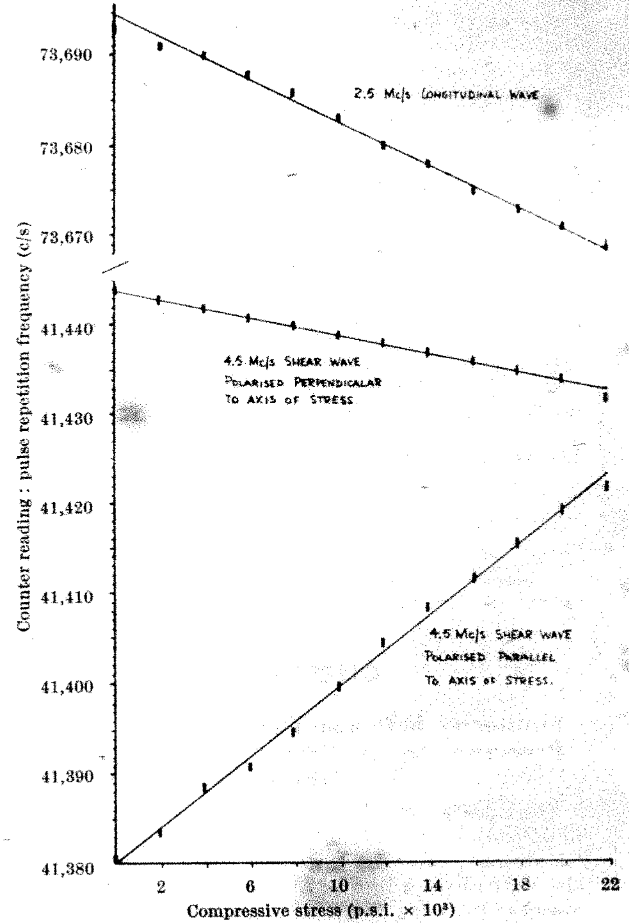

Fig. 1. Graphs of 'sing-around' pulse repetition frequency versus stress

$$\rho_0 c_{1_y}{}^2 = \lambda + 2\mu - \frac{T}{3K_0}\left[2l - \frac{2\lambda}{\mu}(m + \lambda + 2\mu)\right]$$

$$\rho_0 c_{2_y}{}^2 = \mu - \frac{T}{3K_0}\left[m + \frac{\lambda n}{4\mu} + \lambda + 2\mu\right] \qquad (1)$$

$$\rho_0 c_{2_z}{}^2 = \mu - \frac{T}{3K_0}\left[m - \frac{\lambda + \mu}{2\mu}\cdot n - 2\lambda\right]$$

where T is the compressive stress, acting along the y axis, c_{1_y} is the longitudinal wave velocity, c_{2_y} and c_{2_z} are the velocities of the shear waves, polarized parallel and normal respectively to the stress axis. The unstressed density is expressed as ρ_0, $K_0 = \lambda + 2/3\,\mu$ is the unstressed bulk modulus, λ and μ are the Lamé constants, and l, m, and n are the second-order or Murnaghan constants. Each velocity may be expressed in the form

$$c = c_0\left(l + \frac{\Delta c}{c_0}\right) \qquad (2)$$

where c_0 is the unstressed velocity and $\Delta c/c_0$ is the fractional change due to the stress. As this latter is very small, its square may be ignored, and thus for practical purposes:

$$c^2 = c_0{}^2\left(1 + 2\,\frac{\Delta c}{c_0}\right) \qquad (3)$$

If the last expression is substituted into equations (1), it may be seen that the linear relation between stress and velocity is to be expected on the basis of the second-order elastic theory.

The measured values of ρ_0 and c_0 were used to find λ and μ from the expressions:

$$c_{20}^2 = \frac{\mu}{\rho_0} \text{ and } c_{10}^2 = \frac{\lambda + 2\mu}{\rho_0} \qquad (4)$$

The above values and the measured values of T and fractional velocity changes were then used to find the values of l, m, and n from equations (1). The values are compared in Table 1 with those obtained by other workers[3].

The values for nickel steel will be checked in the near future by making measurements with further types of wave/stress combinations, and it is also intended to extend the work to other metallic materials.

CHEMISTRY

Similarity between Theories of Rhythmic Precipitations of Crystalloids and Specific Proteins

HEDGES[1] pointed out that critical condition and mobilization of material are factors common to the Liesegang phenomenon. Mobilization occurs when the critical condition is being approached, with the material diffusing from the zones which become clear spaces to those which become rings. Spiers and Augustin[2], in their theory of the one-dimensional immunodiffusional problem, assumed a zone of reaction in which antigen and antibody combine to form non-diffusing complexes, causing diffusion of the antibody into the zone. Here, experimental evidence is given that inward diffusion actually occurs during precipitation with specific proteins as well as with crystalloids, and results in the occurrence of the translucent zone.

The simple diffusion in two dimensions[3] with two sources of diffusion was used. Fig. 1 shows such an experiment. Normal human serum as antigen and rabbit's antiserum were used. The translucent zone without precipitate at the plane of separation between two precipitation patterns is visible.

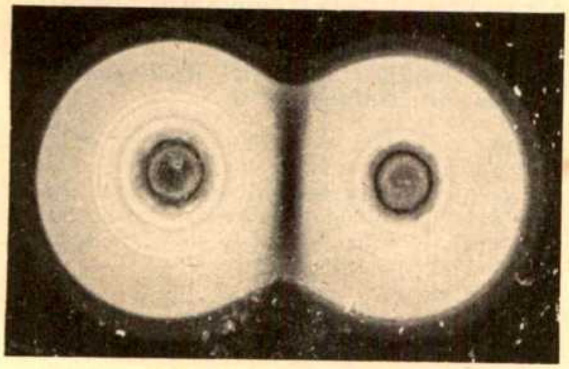

Fig. 1

There are two mechanisms which can possibly cause occurrence of the translucent zone: (1) dissolution of the precipitate or (2) decreased antibody concentration in this zone. Dissolution of the precipitate occurs in a case of excess of antigen[4]. In the system presented the diffusing reactants meet at the plane of separation, and in the absence of the concentration gradient across the plane the flow will be opposed. Therefore accumulation of the antigenic material will occur at this plane. Because the material always flows in the direction of a falling concentration gradient, the concentration of the antigenic material at the plane of separation cannot be higher than those at the points which are nearer to the sources of diffusion: and since intensity of the precipitate decreases in the direction of decreasing concentration, the mechanism of the dissolution of the precipitate cannot be responsible for the occurrence of the translucent zone. The remaining mechanism of decreased concentration of the antibody indicates inward diffusion.

Fig. 2 represents a diffusion experiment between equal concentrations of two sources of one salt. Gel of 0·5 per cent purified Difco-agar and 0·01 M solution of barium chloride was used as the indicator in the gel. A 1 M solution of ammonium sulphate was used. Here as in Fig. 1 the occurrence of the translucent zone also indicates inward diffusion.

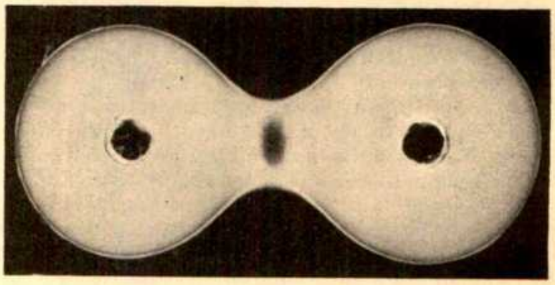

Fig. 2

Diffusion is defined as the mutual interdiffusion of at least two components. To explain the occurrence of the translucent zone this concept may be stated in the following way. In the system presented there is simultaneous movement, or inward diffusion, around two sources of diffusion. When at the given distance between sources of diffusion two zones of movement combine, the movement in this area is equal to the effects of both diffusing sources. Therefore, the concentration of the internal reactant is not distributed uniformly in the medium but is at the minimum concentration along a line of centres where combination first occurs, and gradually increases along other radii. This change in relative concentration of the internal reactant may also result in altered rate of diffusion of the reactants diffusing from adjacent wells[5].

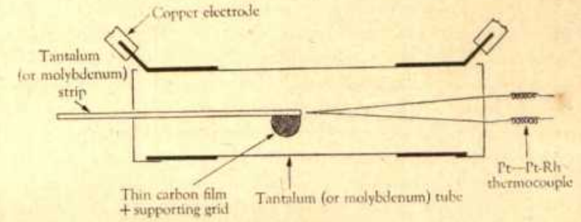
Face-centred Cubic Molybdenum Monocarbide

THREE forms of molybdenum monocarbide (MoC) having a hexagonal unit cell have been reported in the literature[1]. In a recent note, Clougherty, Lottrop and Kafalas[2] have described a high-pressure synthesis of a new face-centred cubic molybdenum carbide, which they designate α-MoC. This material was prepared by heating an equiatomic mixture of molybdenum and carbon or dimolybdenum carbide and carbon at temperatures between 1,800° C and 2,500° C under pressures ranging from 40–70 kb. The reported lattice constant was 4·27 Å.

In recent work in these laboratories, the effect of heat-treating amorphous films of carbon *in vacuo* has been examined by electron diffraction methods. The carbon films were prepared in the usual way by evaporation *in vacuo* and deposition on a glass substrate. The films (about 1,000 Å thick) were detached and supported on grids or foils made from three different materials, namely, molybdenum, tantalum and carbon, so that they could be examined in the electron diffraction camera. The supported carbon films were heated in simple tube furnaces made from molybdenum or tantalum (Fig. 1) to temperatures up to 1,400° C, for periods of 15 sec in a residual air pressure of about 10^{-4} mm mercury.

The diffraction patterns obtained from the unsupported regions of the carbon films heated to 1,400° C on a molybdenum, tantalum or carbon support in the tantalum furnace showed only diffuse rings due to a highly disordered carbon, the rings becoming sharper as the temperature of heating was raised. Fig. 2 shows the diffraction pattern from one such carbon film supported on carbon and heated to 1,400° C. On heating the films on the three supporting materials in a molybdenum tube furnace at 1,000° C, the diffraction patterns were similar to those obtained in the tantalum furnace. However, a marked change was observed when the films were heated to a temperature greater than 1,200° C in the molybdenum furnace irrespective of the nature of the film support. The carbon reflexions were no longer visible and the diffraction pattern (Fig. 3) could now be indexed on the basis of a face-centred cubic unit cell having a lattice constant of 4·26 Å.

These observations can be interpreted by assuming that this cubic phase originates in the reaction between the carbon film and a material evaporating from the walls of the molybdenum tube. There are three possibilities to be examined. (1) Metallic molybdenum might be evaporating from the walls of the furnace. Considering that the vapour pressure of molybdenum is only about 5×10^{-13} mm of mercury at 1,200° C, this appears to be unlikely. (2) The molybdenum is transported from the furnace wall to the carbon specimen as a volatile oxide which then reacts to form molybdenum carbide. (It should be noted that the observed cubic structure is not consistent with any of the known oxides of molybdenum.)



Copper electrode
Tantalum (or molybdenum) strip
Thin carbon film + supporting grid
Tantalum (or molybdenum) tube
Pt—Pt-Rh thermocouple

Fig. 1. Arrangement for heating thin films of amorphous carbon

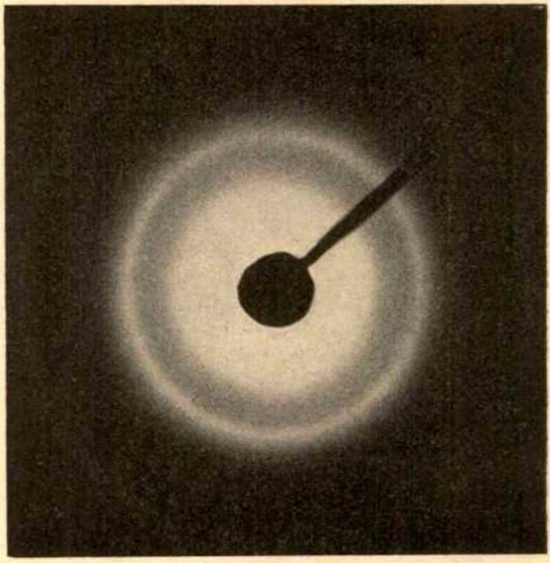


Fig. 2. The electron diffraction pattern from a thin film of carbon heated to 1,400° C for 15 sec in a tantalum tube furnace

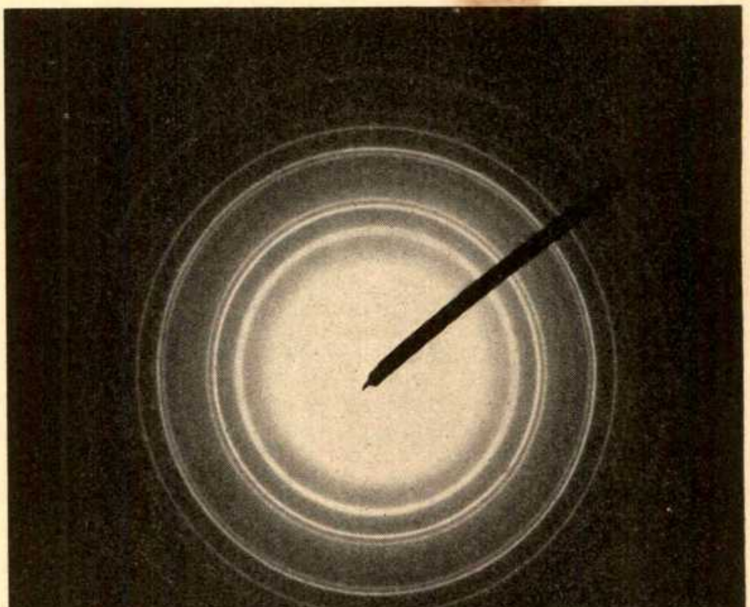

Fig. 3. The electron diffraction pattern from a thin film of carbon heated to 1,200° C for 15 sec in a molybdenum tube furnace

(3) There is a possibility that a volatile impurity in the molybdenum is responsible for the new diffraction pattern. The last suggestion seems to be excluded for the following reasons. The molybdenum sheet (from Murex Ltd.) contained 0·01 per cent iron as the only detectable impurity. Of the possible compounds which could be formed under the experimental conditions, the symmetry of the diffraction pattern is consistent only with cubic ferrous oxide. However, the lattice parameter of ferrous oxide is larger than that found for the phase. In any event the furnace was preheated at 1,500° C for 15 min to clean it up.

There is, therefore, reasonably good evidence that a face-centred cubic molybdenum carbide with a lattice constant of 4·26Å was formed at 1,200° C as a thin film phase in the experiments now reported. This is to be contrasted with the extreme condition of 40–70 kb and 2,000° C used by Clougherty, Lothrop and Kafalas[2] to produce the same structure in bulk.

I thank Mr. D. Clinton for carrying out some of the experimental work. I also thank Dr. G. L. Kington for useful discussions and my thanks are also due to Morganite Research and Development, Ltd., for permission to publish these results.

Raman Spectra of Adsorbed Molecules : Quenching of Fluorescence by Adsorption

It is well known that the infra-red spectra of molecules go through changes in position and intensity by their adsorption on solid surfaces[1–8]. In earlier communications we have shown[9] that the infra-red spectra of organic molecules spread in molecular layers over the surfaces of inorganic salts show differences in position and intensity of the bands compared with the spectra of the bulk substances. The observed differences are greater the more the atomic distances of the vibrating groups coincide with the lattice distances of the salt surfaces. The distortion of molecules with a centre of symmetry by the local fields of the lattice surface causes the appearances of Raman active vibrations in the infra-red.

In this communication we wish to describe some results obtained on the Raman spectra of organic molecules in the adsorbed state. As adsorbing material, aerosil (spec. surface 175 m^2/g), porous glass or potassium bromide powder of great specific surface was used. The Raman spectra were obtained by Brandmüller's method[10] for crystal powders, which has been modified by introduction of an interference filter with great transparency for the Raman lines and a maximum of reflexion for the exciting frequency (4356 Å.). The scattered light was allowed to traverse this filter so that the exciting light could by reflexion pass again through the scattering sample increasing the intensity of Raman lines. Registration was made either photographically or with the aid of a photomultiplier and electronic amplification (*Steinheil*).

The thickness of the scattering powder is critical for the observed intensity of the Raman lines. Changes in that thickness by only 0·05 mm causes the maximum intensity to be passed over. The optimum thickness lies around 0·32 mm, varying from sample to sample. With the aid of a cuvette of variable length in intervals of 0·01 mm it was possible to work at the maximum intensity for the Raman lines.

Table 1

Substance	New Raman lines shown by adsorption on SiO_2 (cm^{-1})	Infra-red frequencies (cm^{-1})
Naphthaline	1,310	1,302
	1,360	1,364
	1,410	1,391 or 1,431
	1,500	1,506
Biphenyl	1,308	1,307
	1,380	1,386
	1,480	1,481
Trans-stilbene	1,220	1,255
	1,609	1,502
Terphenyl	1,112	1,121
Anthracene	960	957
	1,100	1,149

The spectra of biphenyl, naphthaline, anthracene, phenanthrene, terphenyl, trans-stilbene, *p*-nitrophenol, and *p*-nitrotoluol were registered in the state of monomolecular ($n = 1$) and polymolecular (up to $n = 10$) layers. Figs. 1 and 2 illustrate a comparison between the Raman spectra of adsorbed molecules and their spectra in the crystal state. It can be stated generally that the intensities of the lines are very much equalized by the adsorption and that new lines appear (indicated by arrows in the figures) in the case of molecules possessing a centre of symmetry. Table 1 shows that the frequencies of the new Raman lines almost coincide with well-known infra-red bands of the molecules.

It is then possible to register Raman lines of adsorbed molecules only if the adsorbing material has

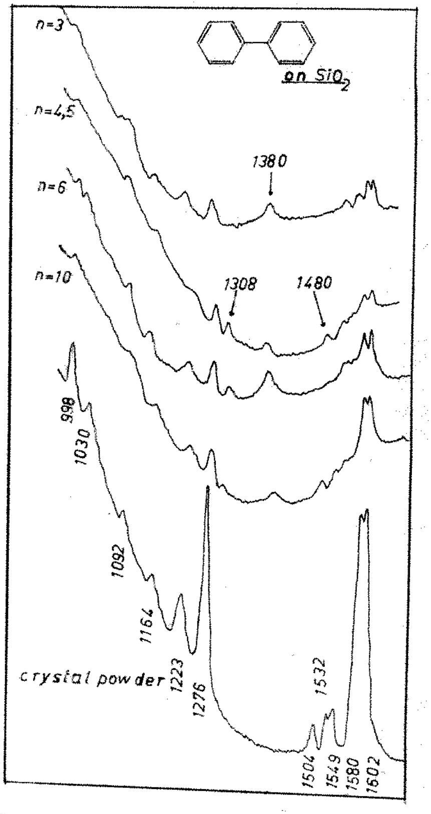

Fig. 1. Raman spectra of biphenyl as crystal powder and adsorbed on silica

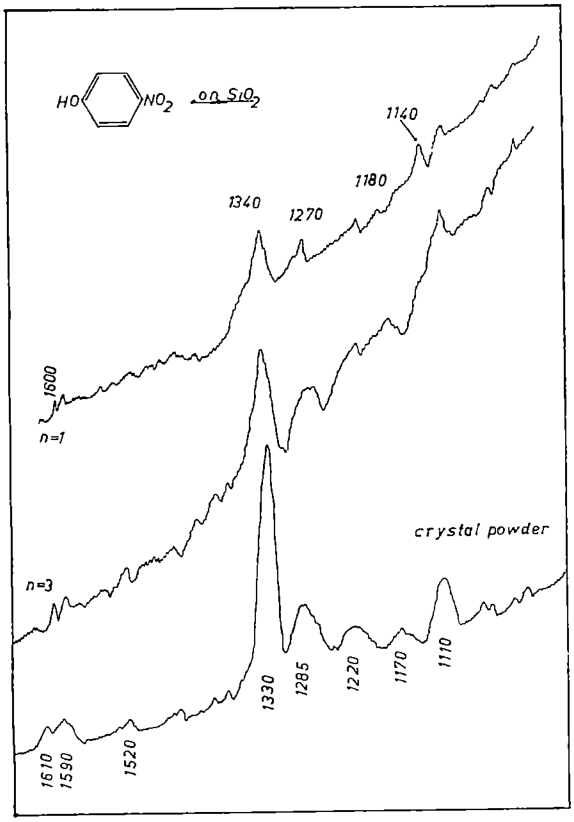

Fig 2 Raman spectra of *p*-nitrophenol as crystal powder and adsorbed on silica

a sufficiently great specific surface In the case of coloured substances detectable intensities of Raman lines are even observable below a monomolecular coverage of the surface, probably due to an increase of intensities by a resonance Raman effect

Another observation made on this occasion is that the fluorescence of molecules is completely quenched by adsorption at a monomolecular coverage The measurement of Raman spectra of fluorescent molecules is possible, using the substances in adsorbed state Fig 3 illustrates, for example, terphenyl, that the fluorescence disappears for $n = 1$, and the covered Raman lines appear

Water as a Chain-transferring Agent in Vinyl Polymerization

IN a previous communication[1] the chain-transfer constant (C_S) of a solvent in a mixed solvent system was determined This opens up the possibility of determining the chain-transfer constant of solvents which are immiscible with the monomer By a suitable choice of a common solvent the heterogeneous mixture of the monomer and the immiscible solvent can be kept in a homogeneous medium, and the C_S value of the latter can be determined An attempt is reported here to determine the chain-transferring capacity of water with the growing radical of poly-(methyl methacrylate) on the above principle

Tert-butyl alcohol was selected as the solvent to keep the mixture of water and methyl methacrylate in a homogeneous phase 1 1 ratio of *tert*-butyl alcohol and methyl methacrylate was taken and different weighed amount of water was added to the ampoule Polymerization was carried out at 60° ± 0 05° C in nitrogen-flushed vacuum-sealed ampoules[1,4] The polymer was precipitated by ethanol followed by reprecipitation from benzene solution The samples were dried *in vacuo* and the viscosity determined by Ostwald viscometer of flow-time 232 sec with benzene The results are shown in Table 1 and Fig 1. The arrow point in Fig 1 indicates the onset of precipitation.

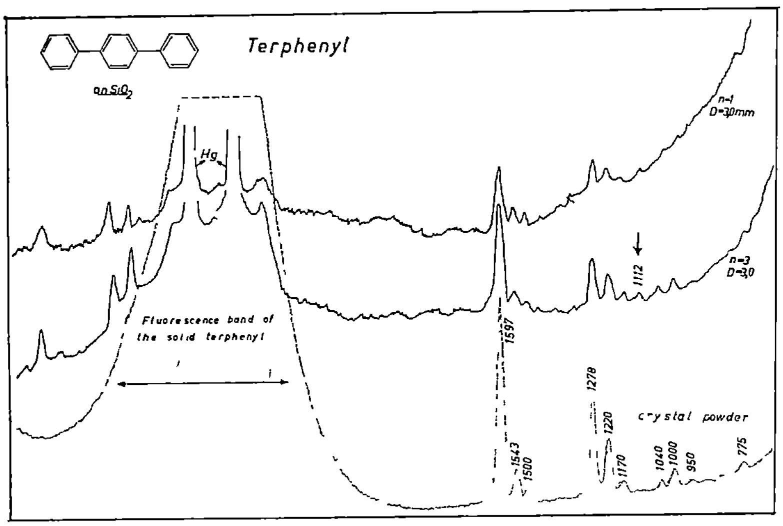

Fig 3 Quenching of fluorescence of terphenyl by adsorption

The most remarkable feature of the result is that addition of water even in small quantity brings about an almost monotonous increase in molecular weight instead of the expected decrease due to chain transfer and dilution A plot of the results, that is $1/\overline{P} - R_p\delta^2/M^2$ against $[H_2O]/[M]$, shows the peculiar nature of the curve Instead of the usual straight line with a positive slope, the curve takes a reverse course, finally becoming almost parallel with the H_2O/M axis This undoubtedly indicates that water has no chain-transferring capacity Jenkins and

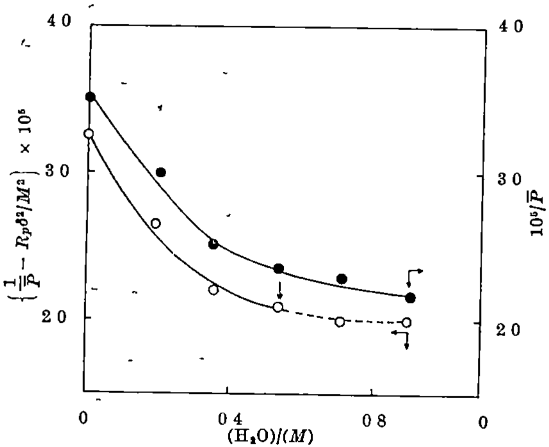

Fig 1 Effect of water on the polymerization of methyl methacrylate in *tert*-butyl alcohol at 60° C

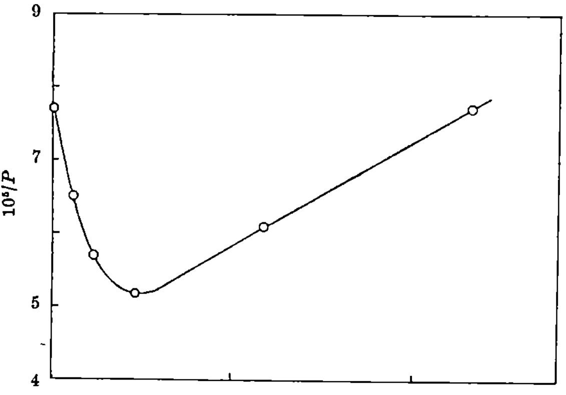

Fig 2 Effect of water on the polymerization of methyl methacrylate in acetic acid at 60° C

Johnston[5] also report that water reduces the reactivity of solvent as a transfer agent This is not surprising in view of the fact that alkyl radicals *X*—CH$_2$—CH*R*, do not react with water[2], and as shown by Merz and Waters[3] that even the highly reactive phenyl radical can persist in aqueous solution until it collides with a suitable solute radical or molecule The unexpected increase in degree of polymerization as also the negative slope of the plot of $1/\bar{P} - R_p\delta^2/M$ against [H$_2$O]/[*M*] can be attributed to a tighter coiling of the polymer chain leading to a reduced termination rate

Table 1 POLYMERIZATION OF METHYL METHACRYLATE IN *tert*-BUTYL ALCOHOL–WATER MIXTURE

Acetic acid/Monomer = 1 1 by volume in each experiment

[H$_2$O]/[*M*]	$10^5/\bar{P}$	Optical density at 515 mμ using rhodamine reagent (polymer solution 0 2%)	Average No of COOH per molecule
0 00	7 67	0 41	very low
0 29	6 56	0 46	0 922
0 58	5 72	0 50	1 75
1 16	5 19	0 50	1-93
2 90	6 11	0 50	1 65
5 80	7 67	0 55	1 79

A slightly different trend is noticeable in the polymerization of methyl methacrylate in acetic acid in the presence of water In this system the quantity of water was varied over a wider range (S/M = 0 29–5 8) The results are tabulated in Table 2 and represented in Fig 2 As in the previous case $1/\bar{P}$ decreases with addition of water and this might be presumed to be due to the same reasons as cited before

In this case also from the point marked with an arrow the system starts to show heterogeneity The new feature which appears here is that from about 1 1 (water/acetic acid) the curve takes an upward turn It is believed that this complication is caused by the increasing ionization of acetic acid introducing in the system a new species, the acetate ion CH$_3$COO$^-$, which probably is a much better chain-transferring agent for poly(methyl methacrylate) radical than acetic acid This also receives support from our results (Table 2, last col) of the number of carboxyl end-groups per polymer chain as determined by the dye interaction method[6] developed in this laboratory The number of carboxyl end groups increases with the addition of water and remains more or less steady on further addition of water

Revision of the End Carbon Chain Concept in the Gas-Liquid Chromatography of Methyl Esters of Unsaturated Fatty Acids

THE 'end carbon chain', shown to be the key factor in relating the retention time of unsaturated fatty acids of differing chain-length but the same number of double bonds, was originally defined as the number of carbon atoms beyond the double bond farthest removed from the carboxyl group[1]

It would be advantageous to redefine this unit as the number of carbon atoms reckoned from the centre of the double bond farthest removed from the carboxyl group to, and including, the terminal methyl group The end carbon chain is then simply the fatty acid chain-length less the familiar position number usually employed to identify this particular double bond position Moreover, the revised 'end carbon chain' concept is immediately useful in assessing the biological activities of certain fatty acids as related through the terminal numbering system[2]

Thermal Isomerization of Poly(triallyl cyanurate) using a Dynamic Mechanical Method

We wish to report a difference in thermo-mechanical behaviour between poly(triallyl cyanurate) and poly(triallyl isocyanurate). In this work a modified torsional pendulum was used in which the vertical specimen shaft consisted of a braid of glass fibres which was impregnated with the polymeric material under investigation. In principle any changes in the mechanical rigidity of this composite would be reflected by changes in frequency of the freely oscillating inertial mass of the pendulum. By expressing the calculated rigidity modulus, G, relative to some arbitrary value, G_0, in each experiment, a relative rigidity parameter, G/G_0, ensued. This parameter partially overcame the difficulties which were inherent in defining the geometry of the system. Experimentally, the relative rigidity reduces to P_0^2/P^2, where P_0 and P are the periods of oscillation at the reference and measured conditions, respectively. The applicability of the measurement of the dynamic mechanical properties of supported polymers to the study of chemical and physical transformations has been demonstrated previously[1-3].

Resins of poly(triallyl cyanurate) and poly(triallyl isocyanurate) were formed on braids of glass fibre from the monomer by polymerization with 1 per cent of benzoyl peroxide at 90° C in nitrogen. After 48 h the rigidity appeared to have levelled off; this was considered to represent the cured state. Fig. 1 represents the curing behaviour in terms of relative rigidity and time. The relative rigidity is based on the rigidity of the cured state, G_f.

The thermoset resins, cured as indicated in Fig. 1, were cooled to room temperature, after which the mechanical behaviour on heating was studied by heating to 500° C over an interval of 180 min. Fig. 2 summarizes these results. Here the relative rigidity is based relative to the rigidity of the composite at room temperature. The difference in thermal softening behaviour between the two resins is apparent. The drastic decrease in rigidity of poly(triallyl cyanurate) at 300° C which is succeeded by an increase at 340° C we believe to be associated with an internal rearrangement, possibly by an intra-molecular cyclic mechanism which is followed by subsequent reaction of allyl groups. The thermal isomerization of normal cyanurates to isocyanurates is well known. The isomerization reaction in poly(triallyl cyanurate) has been investigated by infra-red spectroscopy, differential thermal analysis and calorimetry[4-6]. Additional aspects of the relationship between dynamic mechanical changes and specific chemical reactions in this system will form the basis of a future communication.

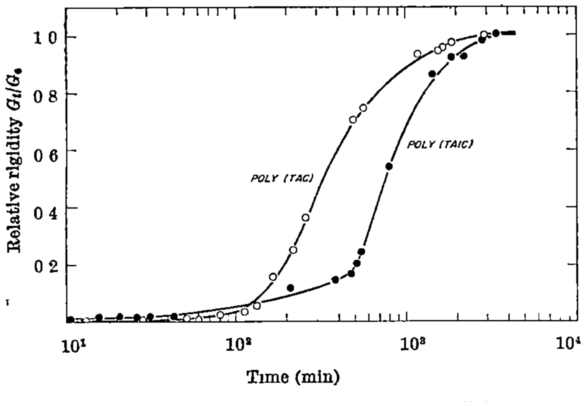

Fig. 1. Polymerization of triallyl cyanurate and triallyl isocyanurate

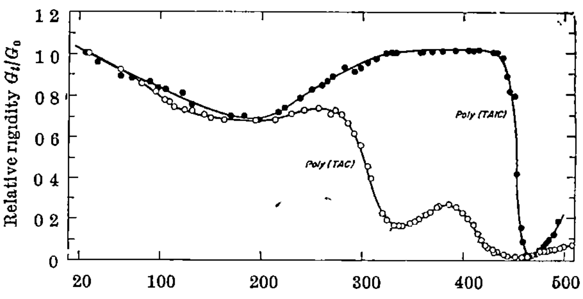

Fig. 2. Thermal softening behaviour of poly(triallyl cyanurate) and poly(triallyl isocyanurate)

It is evident that the torsional braid technique can be used in the examination of transformations which occur in polymeric systems. The method is particularly attractive because a relatively small amount of sample is required (less than 0·1 g) in each experiment and because the changes can be monitored non-destructively. The technique should prove valuable in the study of structural changes which occur in organic, inorganic, biochemical and physiological polymer chemistry.

Effect of Heat on the *p*H of Water and Aqueous Dye Solutions

It appears to be generally accepted that the spontaneous acidity of distilled water is due to dissolved carbon dioxide which can be expelled by boiling to restore the *p*H to about 7·0. Some of my recent work has involved a large number of experiments on the *p*H of water and staining solutions. This brought to light some interesting phenomena which may be of interest to research workers in the field of biology and medicine. In the first place it appears that freshly distilled water usually has a *p*H between 5·0 and 6·0, not 7·0. In the experiments referred to above, whatever the *p*H of the particular sample of distilled water at 20° C it rose gradually until at 100° C it had risen by *p*H 2·0. That is to say if at 20° C the *p*H of the water was 5·0, then at 100° C the *p*H became 7·0, and *p*H 5·5, for example, became 7·5 at 100° C. Graphs were perfectly linear in every case.

The instrument used was an *EIL* direct reading *p*H-meter model 23*A* (Electronic Instruments, Richmond, Surrey); the necessary adjustments were made to permit accurate readings over the temperature-ranges used It was observed that as the temperature of the samples of distilled water fell gradually from 100° C the same pH changes took place but in reverse, so that at 20° C the pH readings observed were exactly the same as those observed before the water was boiled The phenomena might be explained by the following equation

Instead of

$$n(\mathrm{H_2O}) \rightarrow n(\mathrm{H^+}) + n(^-\mathrm{OH})$$

the reaction might be

$$n(\mathrm{H_2O}) \underset{-\text{ heat}}{\overset{+\text{ heat}}{\rightleftarrows}} (n{-}m)\,(\mathrm{H^+}) + m(\mathrm{H}) + n)^-\mathrm{OH})$$

This equation implies that the effects of heat would be to increase the proportion of the hydroxyl ions by decreasing the proportion of hydrogen ions The changes in pH were checked by means of coloured organic indicators

Experiments were also carried out with London tap water, pH 8 2 at 20° C It was found as the temperature was increased up to 60° C so the water became less and less alkaline At 65° C the pH began to rise steadily so that at 100° C the pH of the samples tested was exactly the same as at 20° C

A number of aqueous solutions of acid dyes in distilled water were similarly tested over the temperature-range 0°–100° C As these solutions were heated gradually up to 60° C so their pH fell At 65° C the pH began to rise steadily so that at 100° C the pH observed were exactly the same as at 20° C On cooling the same changes in pH occurred but in reverse

Further investigations are being carried out on the effects of heat on the pH of a large number of acid and basic dyes and will be reported elsewhere Meanwhile it is felt the observations on heat-induced pH changes of distilled water reported here may help to explain, in part at least, the mechanism of some staining methods and also the alleged capriciousness of certain histological stains

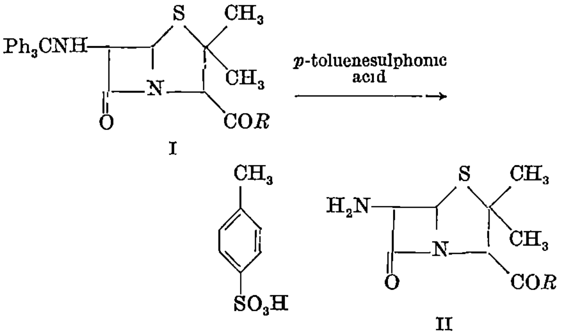
BIOCHEMISTRY

6-Aminopenicillanamide and Methyl 6-Aminopenicillanate

SIMPLE derivatives of penicillins, such as esters[1] and amides[2], have been prepared from the penicillins themselves by conventional methods The availability of 6-aminopenicillanic acid (6-APA) led me to synthesize from it selected carboxylic derivatives which can be used conveniently to prepare corresponding series of penicillin derivatives by acylation of the appropriate 6-APA intermediate

6-Aminopenicillanamide and methyl 6-aminopenicillanate were synthesized *via* 6-tritylaminopenicillanic acid (I, R = OH) The latter compound and its methyl ester have been described by Sheehan and Henery-Logan[3] 6-Tritylaminopenicillanic acid was converted to the amide (I, R = NH_2) and methyl ester (I, R = OCH_3), which were then detritylated to the desired products Removal of the trityl group was readily effected by one equivalent of p-toluenesulphonic acid, which afforded 6-aminopenicillanamide (II, R = NH_2) and methyl 6-aminopenicillanate (II, R = OCH_3), respectively, directly as crystalline p-toluenesulphonate salts



The amide and methyl ester of 6-APA can be differentiated from 6-APA in several paper-chromatographic systems, for example, in one system, methyl ethyl ketone/acetone/water/formic acid, 80 6 12 2[4], the following R_F values are obtained 6-aminopenicillanamide, 0 4, 6-APA, 0 5, methyl 6-aminopenicillanate, 0 8 Detection can be carried out with chemical sprays or by the usual bioautographic method after first subjecting the developed paper-gram to phenylacetylation[5], which enables one to locate the three 6-APA compounds as bioactive spots

6-Aminopenicillanamide p-Toluenesulphonate. Crystalline 6-tritylaminopenicillanic acid diethylamine salt[3], $[\alpha]_D^{24}$ + 102° (C 2 in dioxan), λ_{max} 5 68 (vs) μ in KBr (obtained in 45–48 per cent yield from 6-APA), was transformed quantitatively to the free acid, non-crystalline, $[\alpha]_D^{25}$ + 121° (C 2 in $CHCl_3$), λ_{max} 5 64 (vs) μ in $CHCl_3$ The acid was treated with isobutyl chloroformate and triethylamine in dry acetone to form the mixed anhydride, which was converted *in situ* with aqueous 10 per cent $(NH_4)_2HPO_4$ to 6-tritylaminopenicillanamide in 83–92 per cent yield, non-crystalline, $[\alpha]_D^{26}$ + 175° (C 2 in $CHCl_3$), λ_{max} 5 64 (vs) μ in KBr A solution of 6-tritylaminopenicillanamide (160 g, 0 35 mol) in acetone (200 ml) was stirred, while a solution of p-toluenesulphonic acid (63 36 g, 0 334 mol) in acetone (137 ml) was added rapidly. Precipitation occurred in a few minutes on continued agitation After a total of 13 min , crystalline 6-aminopenicillanamide p-toluenesulphonate was collected by filtration, washed with acetone and ether, and dried (107 g, 83 per cent yield) For analysis a sample was recrystallized twice from aqueous acetone, m p 158–160° (dec), $[\alpha]_D^{24}$ + 197° (C 1 in pH 7 buffer), $[\alpha]_D^{23}$ + 175° (C 1 in ethanol), λ_{max} 5 62 (vs) μ in KBr Anal $C_{15}H_{21}O_5N_3S_2$ requires C, 46 49, H, 5 46, N, 10 85, S, 16 55 Found C, 46 59, H, 5 49, N, 10 54, S, 16 23

Methyl 6-Aminopenicillanate p-Toluenesulphonate Methyl 6-tritylaminopenicillanate[3] (3 64 g, 7 7 mmol) suspended in acetone (7 5 ml) was dissolved by the addition of p-toluenesulphonic acid (1 425 g, 7 5 mmol) Methyl 6-aminopenicillanate p-toluenesulphonate crystallized from solution after stirring for 25 min The product was recovered by filtration, washed with acetone and ether, and dried (1 97 g) The mother liquor furnished an additional 0 32 g, total yield = 76 per cent For analysis a sample was recrystallized twice from warm acetone, m p 133–136° (dec), $[\alpha]_D^{24}$ + 157° (C 1 in pH 7 buffer), $[\alpha]_D^{23}$ + 143° (C 1 in ethanol), λ_{max} 5 57 (vs) μ in KBr Anal

$C_{16}H_{22}O_6N_2S_2$ requires C, 47 74, H, 5 51, N, 6 96, S, 15 93 Found C, 47 85, H, 5 78, N, 6 52, S, 15 85

Fermentation of Saccharose by Alpha-Glucosidase

I HAVE isolated two melibiose-fermenting yeasts, *Saccharomyces oleaginosus*[1] and *S hienipiensis*[2], which, by means of Wickerham's method[3], are capable of fermenting maltose, but which neither ferment nor assimilate saccharose With the Delft method (Kreger-van Rij, N J W , private communication), slow fermentation of the saccharose was obtained

Seven strains of *S oleaginosus* were inoculated in yeast nitrogen base Wickerham (YNB), with 0 5 per cent saccharose or 0 5 per cent galactose or 0 5 per cent galactose plus 0 5 per cent saccharose After 15 days, development was nil in the saccharose tubes but abundant in the rest, in all cases a higher degree of optical density was proved in the tubes containing the saccharose with galactose mixture By means of paper chromatography it was shown that in the tubes of galactose with saccharose only saccharose was present

Identical results were obtained by comparing saccharose, maltose, and saccharose with maltose

With 58 strains of *S oleaginosus*, fermentation of saccharose in 2 per cent concentration in yeast infusion (YI) was compared with fermentation in the same concentration in the medium used by the NRRL of Peoria After 24 days, only 2 strains in YI showed no gaseous fermentation· of the 56 which had fermented, the fastest began fermentation at 7 days, and the slowest at 29 days, in all the tubes, presence of saccharose only was proved by paper chromatography At 42 days, not one of the tubes in the Peoria medium had fermented

A yeast autolysate (YA) was compared with the YI, inoculating from 36 different slants of 2 strains of *S oleaginosus* after 21 days, one of the strains had fermented 2 tubes of the YI, and at 7 days, 24 tubes had fermented in the YA In the other strain, the figures were 5 and 18 respectively

Addition of bromthymol blue to the YI and to the YA had no influence on these results, neither was the result improved by omitting this stain from the Peoria medium

The same strains were inoculated from 10 different slants in the YNB with 0 5 per cent saccharose After 32 days there was no development in any tube, and at 44 days there was positive development in 6 tubes of one of the strains, and 3 in the other

One strain of *S oleaginosus* grown in tubes of YI with glucose, saccharose and maltose, and in YA with saccharose, all of which had fermented, were plated into YI containing agar, eosin, methylene blue[4] and glucose, or saccharose or maltose, also with these same sugars, substituting the YL for YA, in all the cases colonies appeared at 4 days inoculation of the plates, of a dark-red on the glucose and maltose plates, and rose-white on the saccharose plates, independently of the basal medium or whether the inoculation proceeded from tubes with saccharose, glucose or maltose

The former result seems to indicate that the maltose adaptation did not exert any influence on the capability to use saccharose This was confirmed by inoculating the YA and the YI with 2 per cent saccharose from cultures grown in glucose and maltose, because identical results were obtained Nevertheless, when the inoculation was carried out with a large quantity of yeast, there certainly was a more rapid fermentation of the cells which proceeded from maltose, that is to say, the adapted cell is capable of using saccharose directly, and when the number of such cells present in the medium is very high, they metabolize saccharose very fast, but if the inoculation is done with a small number of cells, which have to multiply before they begin fermentation, there is no difference between adapted or unadapted cells

Practically the same results are obtained with *S hienipiensis*

With *S italicus VB* 12–1 the results were as follows in YNB with 0 5 per cent saccharose, the development is positive from 8 to 10 days onwards in all the tubes, this result coincides with the fact that this species normally is considered capable of assimilating saccharose, by means of paper chromatography it was proved that there was no external hydrolysis of the saccharose, fermentation is as slow as or slower than with *S oleaginosus* in any of the media Agar with eosin, methylene blue and saccharose, either in YI or YA, yielded rose-white colonies

Therefore, it seems that it is possible to make the following deductions from these results

(*a*) *S italicus*, *S oleaginosus* and *S hienipiensis* contain no β-fructosidase However, they are capable of induced utilization of sucrose, which very likely involves the induced formation of a maltose transportase[5] that will transport saccharose across the yeast membrane, followed by intracellular hydrolysis of the saccharose by α-glucosidase

(*b*) The utilization (fermentation or assimilation) of saccharose by *S italicus*, *S oleaginosus* and *S hienipiensis* is a property which can be induced by saccharose

(*c*) In this synthesis, in the presence of saccharose, the composition of the medium has a decisive influence *S italicus* carries out synthesis quickly in comparatively simple media, while *S oleaginosus* and *S hienipiensis* demand a much more complex medium

(*d*) Though *S italicus* is quicker in its assimilation of saccharose than *S oleaginosus* and *S hienipiensis*, there is no notable difference among the three species as to their production of carbon dioxide from saccharose

(*e*) In small inoculations, the fact that the inoculations proceed from glucose, maltose or saccharose has no influence on the velocity of the utilization of the saccharose On the other hand, by using abundant cellular masses, the adaptation to maltose and saccharose determines a much more rapid fermentation

(*f*) In taxonomic studies of yeasts, it is impossible to omit specifying in detail all the media used, in order to avoid confusion (*g*) In doubtful cases, it would be convenient to determine whether the saccharose is utilized by the α-glucosidase or by β-fructosidase I consider the qualitative analysis of the culture medium by means of paper chromatography, when the phase of positive development has been reached, as sufficient proof

(*h*) It is necessary not to confuse the adaptive fermentation from saccharose by β-fructosidase (*S fragilis*) with the saccharose utilization by α-glucosidase (*S italicus*, *S oleagenosus* and *S hienipiensis*), though this reaction is also inducible

Adenosine Diphosphate Glucose and Glucoside Biosynthesis

URIDINE diphosphate glucose (UDPG) has been found to act as glucose donor in a number of enzymatic reactions, such as glucoside formation in plants[1] and in locust[2], sucrose and starch synthesis in plants[3,4] and glycogen formation in mammals[5]

Further work showed that adenosine diphosphate glucose (ADPG) is a better substrate for starch synthesis than UDPG, but half as effective as the latter for glycogen formation and nearly ineffective for sucrose synthesis[6]

Arbutin or very similar glucosides were reported to occur naturally in seeds and locusts[7,8] Since arbutin is formed with enzymes either from wheat germ or locust it was considered of interest to test ADPG with these systems, which are known to use UDPG as substrate

With the enzyme from locust[2] ADPG proved to be ineffective for glucoside synthesis On the other hand, using the enzyme from wheat germ[1], ADPG led to the formation of two glucosides which were indistinguishable from those formed when UDPG was used as substrate, that is, arbutin and the corresponding gentiobioside All experiments were carried out with enzyme extracts and methods described previously[1,2,6] For the characterization of the glucosides the reaction with bromine was also used[7,9]

The quantitative results obtained are shown in Tables 1 and 2 It may be observed that the synthesis of glucosides and gentiobiosides is faster when ADPG is substituted for UDPG, but the difference in rates of transfer is not so great as in starch synthesis[6]

Other nucleotides were also assayed as glucose donors in glucoside synthesis Deoxy-ADPG, UDP-maltose and an isomer of UDPG in which the glucose is joined to UDP through position 6 gave negative results Guanosine diphosphate glucose, and to a lesser extent cytidine diphosphate glucose, act slightly as glucose donors, as estimated by nucleoside diphosphate formation in the presence of hydroquinone

The reactions of ADPG and other nucleotides with different phenols and enzymes from several sources are now being examined

Table 1. FORMATION OF GLUCOSIDES AND GENTIOBIOSIDES

Substrates		µmoles formed	
Phenol	Nucleotide	Glucoside	Gentiobioside
Hydroquinone	UDPG	0 12	0 03
Hydroquinone	ADPG	0 15	0 05
Arbutin	UDPG	—	0 09
Arbutin	ADPG	—	0 15

The system contained 0 5 µmole, ADPG or UDPG, 0 8 µmole, hydroquinone or arbutin, 0 15 µmole, ethylenediamine tetraacetic acid, 0 15 µmole, cysteine, 30 µmoles *tris*(hydroxymethyl)aminomethane–maleate buffer (*p*H 6 8), 0 08 ml , wheat germ enzyme (fraction I), (ref 1) Total volume, 0 2 ml The reaction mixture was incubated 60 min at 37° and chromatographed The spots containing glucoside and gentiobioside were eluted and estimated as previously reported (ref 1)

Table 2 FORMATION OF UDP OR ADP

Substrates		µmoles of UDP or ADP formed		
Phenol	Nucleotide	10 min	25 min	40 min
Hydroquinone	UDPG	0 006	0 015	0 025
Hydroquinone	ADPG	0 011	0 023	0 045
Arbutin	UDPG	0 008	0 0125	0 020
Arbutin	ADPG	0 014	0 025	0 035

The system contained 0 4 µmole, hydroquinone or arbutin, 0 1 µmole, cysteine, 0 1 µmole, ethylenediamine tetraacetic acid, 20 µmoles *tris*(hydroxymethyl)aminomethane–malate buffer (*p*H 6 8), 0 04 ml , wheat germ enzyme (fraction I) Total volume, 0 1 ml The reaction mixture was incubated at 37° for the times indicated and the UDP or ADP formation was estimated (ref 6)

This investigation was supported in part by a research grant (No *G*–3442) from the National Institutes of Health, U S Public Health Service, by the Rockefeller Foundation and by the Consejo Nacional de Investigaciones Científicas y Técnicas

Phage Ghost-induced Spheroplasts of *E. coli* 'B' as a System for Phage Reproductions

THE investigations of various authors have shown that lysozyme protoplasts, as well as penicillin spheroplasts, preserve the biochemical activity of an intact bacterium Synthesis of proteins and nucleic acids is achieved in them[1,2]

The full metabolic value of protoplasts allowed them to be used as a system for the study of the reproduction of phages

In the work reported here, spheroplasts of *E coli B*, obtained by means of treatment with ghosts of phage

T4r, were examined The 'ghosts' were obtained by means of Herriott's method[3] somewhat modified. For the elimination of the residual infective phage, the preparations were subjected to an osmotic shock, and irradiated by ultra-violet light (3 lamps at 15 W) for 5–7 hr The spheroplasts were maintained in a hypertonic medium with sucrose and magnesium sulphate The number of 'ghosts' per bacterium was equal to 2,500–3,000 parts The spherical bacterial forms obtained were osmotically fragile but retained a modified cell wall and they had the capacity of absorbing partly the heterologous phages But in these ghost-induced spheroplasts, neither homologous nor heterologous phages were reproduced

During the preliminary infection of the cells by an intact phage and the subsequent transformation of them into spheroplasts, it was established that the suppression of phage reproduction results only from treatment of the infected cells by phage ghosts during first minutes after initial infection (Table 1)

Table 1. REPRODUCTION OF PHAGE *T4r*+ IN THE SPHEROPLASTS OF *E coli* INDUCED BY 'GHOSTS' OF THE PHAGE *T4r*+ FOLLOWING DIFFERENT INTERVALS OF TIME AFTER INFECTION

	Composition of the mixture	Time of treatment of bacteria after their infection by the phage (min) 1	2	4	5
		Coefficient of increase of the titre of phage during subsequent incubation of infected bacteria for 40 min at 37° C			
Exp	Bacteria infected by *T4r* and treated by the 'ghosts' of the same phage	2	1	1 4	18
Cont	Bacteria infected by phage *T4r*+ and treated by sucrose in medium *F*	22	29 4	15 6	16

It was concluded that the phage 'ghosts' suppress in the bacterial cells those reactions which are initiated immediately after the penetration of the phage DNA These reactions could be either the blockage of early protein synthesis[4] or of RNA[5]

In order to check this suggestion, biochemical experiments were carried out the aim of which was the examination of the influence of 'ghosts' on the synthesis of protein and nucleic acid of the non-infected cells

In the biochemical experiments a 4-hourly broth culture of *E coli B* was used, treated by the phage 'ghosts' in such a quantity that there were 100 phage particles per bacterium. A non-treated culture was used as control

The two bacterial preparations (experimental and control) were incubated at 37° C and during definite intervals of time samples were taken for the determination of the contents of protein, nucleic acids and acid-soluble compounds[6]

From Fig 1 it can be seen that in the bacterial culture treated with phage 'ghosts' a complete suppression of protein and DNA synthesis occurs and also a considerable diminution of RNA content Also, one can observe a corresponding reduction in the total quantity of nucleic acids and an increase of acid-soluble compounds absorbing ultra-violet light

The difference of our results relating to the velocity of accumulation of acid-soluble compounds from those obtained by Lehman and Herriott[7] possibly can be explained by the fact that in our experiments the number of 'ghosts' per bacterial cell was considerably greater

The mechanism of the diminution in RNA and acid-soluble compounds observed by us is not clear One may assume that the protein walls of the phage are activating RNase, but at the same time they can block the synthesis of RNA in the bacteria From these suppositions, one may assume that the accumulation of the acid-soluble compounds in the culture, subjected to the action of the phage 'ghosts', could occur at the expense of nucleotides produced by the action of RNase, or at the expense of the RNA precursors or at the expense of both The reduction of the synthesis of RNA can be produced by increase of the penetrability of the cell under the influence of 'ghosts', which is responsible for entry into the medium of the RNA precursors

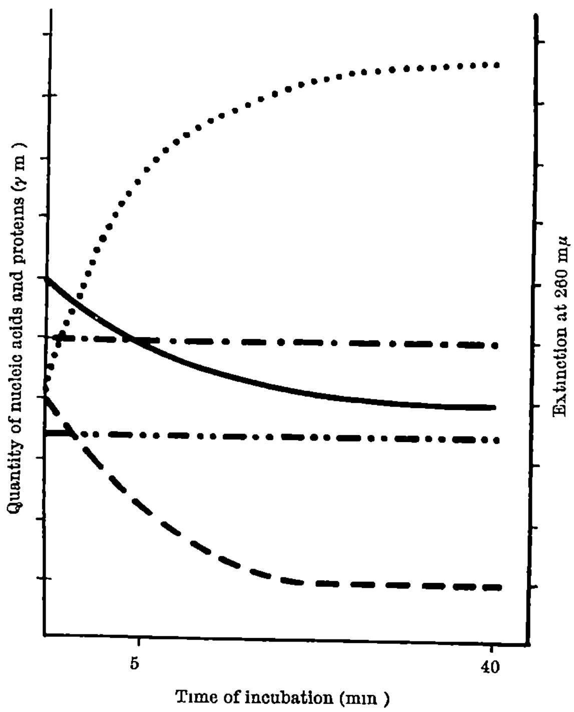

Fig 1 ——, Total quantity of nucleic acids, – – –, RNA, – –, DNA, , acid-soluble compounds, – –, protein

Comparison of the experimental results on phage reproduction with the results of the biochemical experiments suggests that the incomplete value of phage spheroplasts as a system for phage reproduction could be explained by the reduction of the synthesis and destruction of RNA, forming in the cell immediately after the infection of the phage, which as was shown in earlier work is necessary in the first stages of its reproduction[8–11]

Isolation of Progesterone from Human Pregnant Myometrium

ZANDER[1] has reported that "with the methods presently available it has never been found possible to demonstrate non-labelled progesterone or either of the Δ4-3-ketopregnene-ol-one isomers in the target tissues, uterine muscle and mucosa" With the aid of gas-liquid phase chromatography we have isolated non-labelled progesterone from the human pregnant myometrium and this report deals with the method used and the concentrations of the steroid found

The technique for qualitative and quantitative isolation of progesterone, using gas-liquid phase chromatography, was first perfected in placental tissue The details of this procedure have been described elsewhere[2] Essentially it consists of 5 per cent sodium hydroxide digestion, extraction of crude lipids with ether, partial purification of cholesterol on silicic acid column and final separation of progesterone on gas chromatogram using 2 per cent '*SE* 30' (General Electric) as liquid phase

The qualitative identification of progesterone was confirmed by the following procedure

(1) The retention times on the gas column chromatogram for the other closely related steroids were obtained and none of the steroids tested had the same retention time as progesterone

(2) The peak from the gas column which displayed the same retention time as crystalline progesterone was collected and subjected to ultra-violet absorption analysis Both the tissue extract and the standard exhibited maxima at 240 mμ were suggestive of unsaturated λ-β ketonic di-substitution

(3) The 'progesterone' peak from analysis of the tissue on the gas column was also subjected to bioassay by a modification of the McGinty procedure[3] and gave a 4+ response for progesterone in the endometrium of rabbits (We thank Dr Arthur L Haskins, of the University of Maryland, Baltimore, for the bioassays and ultra-violet absorption spectra)

After establishing with placental tissue the technique for the isolation of progesterone by gas column chromatography, human myometrium was analysed using the same procedure In order to obtain a peak suitable for accurate measurement, however, the myometrial tissue samples had to be in the range of 40–45 g each, therefore confining the studies to women having cæsarean hysterectomy

Table 1 MYOMETRIAL PROGESTERONE

No	History	μg progesterone/g wet weight myometrial tissue *P*	*AP*
1	Pooled myometrial biopsies	0 63	0 31
2	Mrs A R —12 weeks	0 15	0 08
3	Mrs R C —38 weeks	0 16	0 10
4	Mrs V T —39 weeks	0 11	0 12

P, myometrium overlying the placental site, *AP*, myometrium directly opposite to placental attachment

With this procedure, 0 08–0 63 μg of progesterone per gram of wet weight of tissue was found (Table 1) Bioassay and ultra-violet absorption spectra were carried out as before The bioassay gave a 1 to 3+ progestin response, and the ultra-violet absorption was in the vicinity of 240 mμ due to very low concentrations In addition, the final extract was run in three different liquid phases, 2 per cent 949, 1 per cent 149–244, 2 per cent '*XF*–1125' (General Electric), and the 'progesterone' peak from the unknown sample had in each of these instances the same retention time as the standard progesterone

Finally, to eliminate the possibility that these small amounts represent measurements of plasma progesterone retained in the tissues despite the careful blotting of the cut pieces in order to remove blood, hæmoglobin determinations were carried out and the maximum plasma content estimated as 8 5 ml/100 g wet weight (We thank Mr Daniel Kooyman for the analysis of tissue plasma content) Even assuming 15 μg of progesterone per 100 ml of plasma, the determined tissue-levels exceed any reasonable plasma concentration by several-fold (0 012 μg calculated from plasma sources versus the 0 08–0 6 μg found)

Development of H Activity by Human Blood-Group B Substance treated with Coffee Bean α-Galactosidase

THE appearance of H specificity in the non-diffusible products remaining after the enzymatic destruction of A and B blood-group specificities has been observed with enzyme preparations from several different micro-organisms Iseki and Masaki[1] first reported that an A-decomposing enzyme from the bacterium *Clostridium tertium* destroyed the A serological activity of human saliva and hog A preparations and gave products which had H serological activity not shown by the A preparations before enzyme treatment Enzyme preparations from the protozoan *Trichomonas foetus* similarly decompose A substance of human ovarian cyst and saliva origin with the disappearance of A specificity and the appearance of H specificity[2] Extracts from *T foetus* also contain a different enzyme which acts on human B substance with the destruction of B serological properties and the appearance of H specificity[2,3], and bacterial enzymes from *Bacillus cereus*[4] and *Clostridium maebashi*[5] induce the same specificity changes in B substance

The B-decomposing enzymes from these micro-organisms have not been obtained in a sufficiently pure state for their specificity to be determined unequivocally by their action on substrates of known structure On the basis of enzymatic hydrolysis and inhibition experiments, however, a D-galactosidase specificity was inferred Loss of B activity of human ovarian cyst B substance by the action of the partially purified enzyme from *T foetus* was accompanied by the release of reducing sugars (equivalent to 5 per cent of glucose) which consisted of a major galactose component with only traces of fucose and *N*-acetylhexosamine[3], and the enzyme from *Cl maebashi*, when allowed to act on B substance from human stomach linings, liberated about 8 per cent of the original galactose and no other sugar[6] The action of the *T foetus* enzyme on B substance was inhibited by D-galactose and not by any of the other sugars in the blood-group substances[7], and when this inhibition occurred there was no development of H specific activity[2,3] These results therefore suggested that the

* Conditions for hæmagglutination inhibition tests: 0.1 ml. serum, diluted to contain 2–3 completely hæmagglutinating doses, was added to 0.1 ml. of serial dilutions of blood-group substances. The mixtures were left 15 min. at room temperature and 0.1 ml. of a 1 per cent suspension of erythrocytes of the appropriate group were then added. The degree of agglutination was determined by examination under the microscope after 2 hr. at room temperature.

enzymes destroying B specificity were removing terminal D-galactosyl residues and thereby exposing structures closely related to, or identical with, those present in H substance.

The anomeric form of the galactosyl residues in B substance hydrolysed by the enzymes, and consequently the α- or β-specificity of the galactosidases which destroy B serological activity, could not be deduced from the enzymic degradation or inhibition experiments. Insight into the serologically active grouping in B substance had been obtained independently, however, from immunochemical inhibition experiments. Kabat and Leskowitz[8] found that galactose inhibited precipitation in the B-anti-B system and that α-methyl-D-galactoside and other α-D-galactosyl compounds were better inhibitors than galactose, whereas β-methyl-D-galactoside was a poorer inhibitor. These results indicated that a terminal non-reducing galactosyl unit in the α-configuration is involved in B specificity, and the recent isolation by Painter, Watkins and Morgan[9] of a B serologically active disaccharide, *O*-α-D-galactosyl-(1 → 3)-D-galactose, from human B substance confirms this deduction. The enzymes which destroy B specificity are, therefore, by inference, α-galactosidases. Nevertheless, enzymes which split α-D-galactosyl linkages do not invariably act on B substance with a loss of B serological activity. Enzyme preparations from brewers' yeast[10], almond emulsion[11] and *Patella vulgata*[12], which actively hydrolysed melibiose and *p*-nitrophenyl-α-D-galactoside, were without action on B substance[13]. Zarnitz and Kabat[14], however, found that a purified α-galactosidase from coffee beans[15] splits galactose from B substance with a reduction in the power of the substance to precipitate a human anti-B serum and a complete destruction of the capacity of the substance to inhibit hæmagglutination of B red-cells by an anti-B serum. About 5 per cent of reducing sugar was liberated from the B substance and, on fractionation on a charcoal: celite column, this sugar was shown to consist almost entirely of galactose with only a trace of methyl pentose and no detectable hexosamine or acetylhexosamine. The enzyme preparation was without action on lactose, showing the absence of a β-galactosidase, and it was therefore concluded that loss of B activity resulted from the action of the α-galactosidase in the coffee bean preparation. In this communication we wish to report that a development of H activity accompanies the loss of B activity when B substance is treated with the coffee bean α-galactosidase.

H activity was measured in hæmagglutination inhibition tests with a rabbit anti-H serum[16]. The materials tested have been described previously[14] and were (1) the untreated B substance (Beach), (2) the whole lyophilized residue obtained after enzyme treatment (Beach E.T.), (3) the insoluble material obtained on extraction of the whole lyophilized residue with 90 per cent phenol (Beach E.T., phenol insoluble), (4) the material recovered from phenol by the addition of 20 per cent (v/v) ethanol (Beach E.T., 20 per cent p.p.t.). The low H activity of the untreated B preparation is considerably increased as the result of the action of the coffee bean α-galactosidase (Table 1), and this H activity is associated with both the fractions obtained after extraction of the enzyme-treated non-dialysable residue with phenol.

The H activity developed by B substance after treatment with the B-decomposing enzyme from *T. foetus* was first reported to be equivalent to about 10 per cent of the activity of a purified H substance[3]. In later experiments, when a more highly purified enzyme was used, H inhibition titres equivalent to 25–50 per cent of the activity of H substance were obtained[2]. Crude extracts from *T. foetus* contain an enzyme which destroys H serological activity, however, and it is difficult to free the enzyme acting on B substance from all traces of this contaminant. The materials which remain after treatment with the coffee bean α-galactosidase have H activities equal to 50–100 per cent of the activity of a purified human H substance (Table 1), in the absence of an enzyme which destroys the newly exposed H reactive structures, therefore, the removal of galactose from B substance gives rise to a material which has virtually the same activity in hæmagglutination inhibition tests as an untreated H substance. In double diffusion tests in agar gel, the α-galactosidase-treated B substance gave a precipitin line with rabbit anti-H serum which fused with that given by human H substance, this line was not given by the untreated B substance.

Mild acid hydrolysis of group B substance liberates fucose and various oligosaccharides and exposes other terminal non-reducing α-galactosyl units which confer a new, BP1, specificity on the molecule[17]. Galactose is also split from BP1 substance by the coffee bean α-galactosidase with a resultant loss of both the residual B specificity and the newly formed BP1 specificity[14]. The enzyme-treated BP1 substance (Beach P1 *E.T.*) was divided into two fractions, Beach P1 *E.T.* 10 per cent, and Beach P1 *E.T.* 20 per cent, by precipitation from phenol solution with ethanol[14], and when the BP1 materials were tested for development of H specificity only a small increase in activity was observed (Table 1), it can be assumed that this increase results from removal of galactose from the remaining B specific groupings in the molecules and not from the BP1 structures.

Stepwise enzymic degradation of group B substance, first with a purified B decomposing enzyme from *T foetus*, and, secondly, with an H decomposing enzyme from the same organism, results in a material which has blood-group Le^a activity considerably in excess of that detectable in the original preparation or in the H-active material formed as the result of the first enzyme treatment[2,18] Since treatment with the coffee bean preparation corresponded to the first step in this degradation procedure, an increase in Le^a activity was not to be expected When the B and BP1 fractions were tested for hæmagglutination inhibition in the Le^a system, no significant change in the Le^a titres was observed between the control and the enzyme-treated substance (Table 1)

The demonstration that H activity is developed by B-substance on treatment with the purified α-galactosidase from coffee beans provides confirmatory evidence that the H active groupings are exposed as the result of the removal of terminal α-linked galactosyl units from the B specific structures

Activation of Endogenous Plasma Proteolytic Enzymes with the Consequent Production of Pharmacologically Active Polypeptides

The transfusion of human antihæmophilic globulin concentrate (EHF) routinely prepared in this laboratory by the method of Kekwick and Wolf[1] was found to give clinical reactions[2] resembling the effects of a plasma kinin[3]. As EHF contains plasminogen and fibrinogen as well as other clotting factors, and as human plasmin is known to produce a kinin from pseudoglobulins[4], the possibility that the reactions were due to a kinin produced as a result of plasminogen activation in EHF was explored

Kinin was assayed on the isolated guinea pig ileum against an alcoholic extract of a tryptic digest of human α-globulin, the potency of which had been determined in terms of synthetic bradykinin (Sandoz '*BRS* 640') Results are expressed as ng synthetic bradykinin/ml The activation of plasminogen was determined by estimating the amount of fibrinogen in the EHF hydrolysed after incubation at 37° as indicated by the increase in the optical density at 280 mμ of a trichloroacetic acid filtrate, expressed as μg tyrosine/ml When EHF was incubated with streptokinase (Lederle) plasminogen activation was followed by kinin production In 10 batches of EHF the increase in kinin, which was maximal after about 60 min, although fibrinogenolysis continued, varied from 19–83 ng bradykinin/ml The kinin was isolated by distillation at reduced pressure from the alcoholic filtrate obtained after precipitating the protein of activated EHF with 3 volumes of boiling ethanol , or by chromatography on 'Sephadex *G* 75', when 92 per cent of the active material was found in association with a small molecular fraction equivalent to 1 2 per cent of the initial protein A kininogenetic system was thus demonstrated in EHF, and the clinical reactions observed could be due to the activation of EHF plasminogen by a plasma or tissue activator.

The initiation of blood clotting by the activation of Hageman factor by glass[5] is followed by the production of a plasma kinin[6], and, it has been claimed[7,8], by the activation of plasminogen It seemed possible, therefore, that an intrinsic plasminogen activator which could be isolated from plasma by adsorption on a silica surface could cause the *in vivo* production of kinin from EHF As Hageman factor[9] and kininogen activator[10] have been eluted from silica by alkaline saline, the effects of such a fraction were tested on the plasminogen and kininogen in EHF, and in systems where the proenzyme was purified human plasminogen, and the substrate plasminogen-poor fibrinogen or casein

Plasma, derived from blood taken into ACD anticoagulant in plastic bags, centrifuged at 0°, and held at −20° in siliconed bottles until used, was allowed to flow through a column of 'Celite Hyflo' (100 mg/ml), which was then washed with 0 15 M sodium chloride until the effluent was protein free The column was then eluted with 0 15 M sodium chloride brought to *p*H 11 0 by adding sodium hydroxide, until the effluent was again free from protein In 10 different preparations 'Celite' eluate (CE) containing 0 24–0 44 mg N/ml and 0 7–1 4 per cent of the initial plasma protein was obtained Plasminogen was prepared by the method of Sgouris *et al* [11] and plasminogen-poor fibrinogen (SF) by that of Kekwick *et al* [12] A comparison of the effects of incubating EHF and SF with saline, CE or streptokinase for 60 min at 37° showed that from EHF, CE produced 13 μg acid-soluble tyrosine, and 42 ng bradykinin, while streptokinase produced 115 μg acid-soluble tyrosine and 53 ng bradykinin Because of the almost complete lack of plasminogen only traces of both substances were produced from SF When EHF and SF were incubated with glycerol-activated plasmin, EHF produced 98 μg tyrosine and 72 ng bradykinin, and SF 69 μg tyrosine, but no bradykinin. This shows that the kinin is not produced by the hydrolysis of fibrinogen

Streptokinase 200 units	298 S_3	,,	135	162
None	298 S_3	,,	0	8

CE was also incubated with purified plasminogen for 30 min at 37° before adding the mixture to substrate In each experiment activation by CE was compared with that by streptokinase, with the effect of plasminogen alone and with the effect of activators without added plasminogen Table 1 shows that plasminogen was activated by CE, in excess of the autoactivation taking place, and CE itself contains no plasmin, since the small amount of plasminogen in SF was equally activated by CE and streptokinase

A preparation of CE, concentrated by pressure dialysis against pH 8 6 veronal buffer I 0 1, was examined by electrophoresis on acetyl cellulose in the same buffer[13], the protein being stained with naphthalein black By comparison with normal plasma examined at the same time, CE was a mixture of α_1-, α_2- and β_2-globulins The relative proportions were calculated by estimating, in a Hilger spectrophotometer[14], the optical density at 630 mμ of dyed protein on a strip cleared with Whitemor oil 120, and found to be 12 per cent α_1-, 78 per cent α_2- and 10 per cent β_2-globulin

The observations described confirm those of previous workers[7-10] In addition we have found that CE activates plasminogen as well as kininogen, and in EHF could produce conditions which might give rise to a clinical reaction on transfusion The kininogen substrate is not known, but differences between EHF and SF as substrate for plasmin digestion indicate that it is not fibrinogen

Gastric-stimulating Factor in Meat Extract

It was first shown by Pavlov[1] that meat extract was a powerful stimulant of gastric secretion when given by mouth Later workers confirmed this but failed to identify the compounds responsible for the effect (for a review, see ref 2) Following a full investigation of the constituents of meat extract[3,4], a sustained effort was made to identify the gastric stimulating factor, with the results presented here

Gastric secretion was measured with Davies's technique[5] by following the uptake of carbon dioxide of a bag of isolated toad mucosa contained in a double side-armed Warburg flask A plot of manometer readings against time gave a line of constant slope changing abruptly to a line of greater slope (increased secretion) when a stimulating agent was added from the side-arm At the end of each experiment in which no stimulation of gastric secretion was observed, histamine (to a concentration of 5 6 μg/ml) was added as a control to determine whether the failure to stimulate was due to the use of the occasional non-secreting mucosa A measure of the activity of a given sample was obtained by dilution with saline to a point where a response was no longer obtained Using this technique, commercial meat extract and an extract of fresh muscle were active, while a mixture of the compounds identified in meat extract[6] was inactive, both before and after heating Riboflavin, 5-hydroxytryptamine, synthetic carnosine and synthetic carnitine were all inactive

The histamine in the sample was concentrated by saturating a solution of meat extract at pH 10 with sodium sulphate and extracting with n-butanol The amount of histamine was estimated, by comparison with known amounts of standard, on paper chromatograms and found to lie between 0 004 and 0 008 per cent of the extract This is equivalent to 0 012–0 024 μg/ml in the 300 μg/ml of extract, which is the minimum amount that gives a response in the assay

Since the minimum amount of pure histamine giving a response was in the region of 0 05 μg/ml and the extract still stimulated after the free histamine had been extracted, it was concluded, at this stage of the investigation, that histamine was not the active principle

A ten-fold purification of the activity of meat extract was achieved as follows Meat extract was blended with 5 vol of ethanol in a Waring blender, the alcohol extract concentrated to half-volume and an equal volume of acetone added The amorphous cream-coloured precipitate was centrifuged off and redissolved in water Paper chromatography showed the presence of creatine, creatinine, hypoxanthine, carnosine, carnitine, and traces of amino-acids. Physical and chemical tests combined with bioassay revealed that the active factor was dialysable, soluble in polar organic solvents, basic and probably contained an amino-group since the activity was destroyed by acetylation, deamination and oxidation with hydrogen peroxide, and was unaffected by hydrolysis in 6 N acid or alkali

Active material was chromatographed on paper in a number of solvents and the activity located by cutting up the chromatograms and assaying the zones After chromatography of meat extract in butanol–acetic acid the active principle was found to coincide with a narrow band of yellow material having a blue fluorescence in ultra-violet light of wave-length 247 mμ, but in isopropanol–ammonia it was separated from the fluorescent material which remained near the origin. As evident from Table 1, the active factor had quite different R_F values from histamine in two of the solvents tested.

Table 1

	R_F factor Active factor	 Histamine
n-Butanol–acetic acid–water (ref. 7)	0·45	0·22
Isopropanol–concentration ammonium–water (ref. 7)	0·52	0·52
n-Butanol–pyridine–water (ref. 7)	0·37	0·47

When the concentrated material was run in butanol-acetic acid, activity was found at two positions on the chromatogram corresponding to $R_F = 0·22$ and 0·45. However, after acid- or alkaline-hydrolysis only one active spot $R_F = 0·22$ was found. Examination of the action of the two materials R_F's 0·22 and 0·45 on the isolated guinea pig intestine indicated that both these compounds had a histamine-like effect which was inhibited by promethazine.

The concentrated material was treated to chromatography in ethanol solution on a column of cellulose powder. The effluent was fractionated arbitrarily and each fraction tested for activity. The active fractions were combined to give a further purification of approximately five-fold. Paper chromatography of this material showed the presence of a faint diazo-reacting spot at R_F 0·45 in butanol–acetic acid. When histamine hydrochloride was added and the mixture chromatographed, two strong diazo reactors now appeared at R_F 0·22 and 0·45. After hydrolysis only the material at 0·22 was found.

It is suggested that the added histamine reacted with one of the substances present in the partially purified sample from meat extract to form a complex at R_F 0·45 and that a similar material is the active principle naturally present in the extract. West and Riley[8] have observed a similar change in the chromatographic behaviour of histamine present in tissue extracts, and Beckett, Beaven and Robinson[9] have shown that double spot formation may take place with a number of naturally occurring amines, and is repressed by basic solvents.

The activity of meat extract in stimulating acid gastric secretion when administered by mouth has not been explained, but it seems likely that the postulated histamine complex is active by this route at low concentrations whereas free histamine causes secretion only in very large doses.

PHYSIOLOGY

Tolerance to Severe Heat and the Behaviour of Respiratory Minute Volume in Cattle

In an attempt to find whether various degrees of tolerance to severe heat in cattle are associated with significant changes in respiratory minute volume, the following experiment was conducted. Each of 8 Ayrshire bull calves, aged 7–11 months, was exposed 3 times in a climatic room[1] to an atmosphere of 40° C dry bulb and 38° C wet bulb temperature, until its rectal temperature reached 42·0° C. Every 10 min., throughout exposure, the volume and frequency of respiration were determined with a pneumotachometer[2] and the rectal temperatures measured with thermocouples[3]. Heat tolerance was expressed in terms of rate of rise of rectal temperature (°C/hr.).

The most heat-tolerant animal (No. 3) could tolerate the hot atmosphere for 175 min., corresponding to a rate of rise of rectal temperature of 1·03° C/hr. The corresponding figures for the least heat-tolerant animal (No. 7) were 97 min. and 1·85° C/hr.

The relation between rectal temperature response and respiratory response of the 8 animals is shown in Fig. 1. The regression coefficient given in the equation is statistically significant. Under the conditions of this experiment, where rectal temperature rose virtually linearly with time of exposure, a mean increase in the rate of rise of rectal temperature of 1° C/hr. corresponded to a mean increase in respiratory minute volume of 90 litres.

The animals tested from July until September (Nos. 1, 2, 3 and 4 in Fig. 1) were more heat tolerant than those tested from November until January (Nos. 5, 6, 7 and 8). The averages of these two groups for rate of rise of rectal temperature were 1·14 ± 0·053° C/hr. and 1·64 ± 0·075° C/hr., the difference of 0·50° C/hr. being statistically significant. This might suggest seasonal acclimatization of the animals tested in the summer.

The finding of a positive correlation between rectal temperature and respiratory minute volume is in agreement with the results of McDowell, Lee, Fohr-

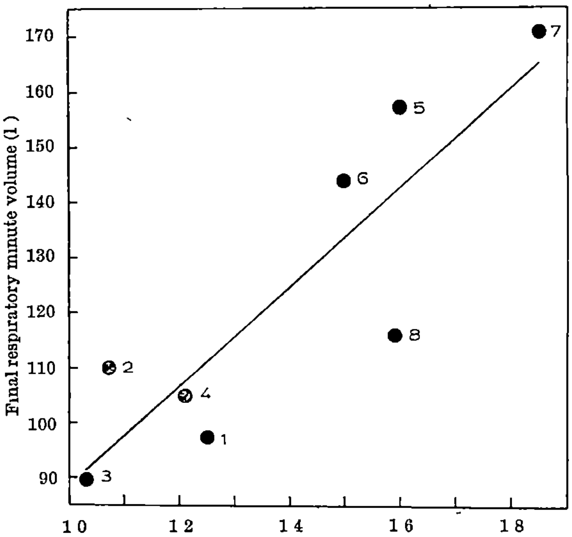

Fig. 1. Regression of respiratory minute volume in litres on rate of rise of rectal temperature. Regression equation $y = 90x - 1·4$. The figures in the diagram refer to the serial numbers of the calves.

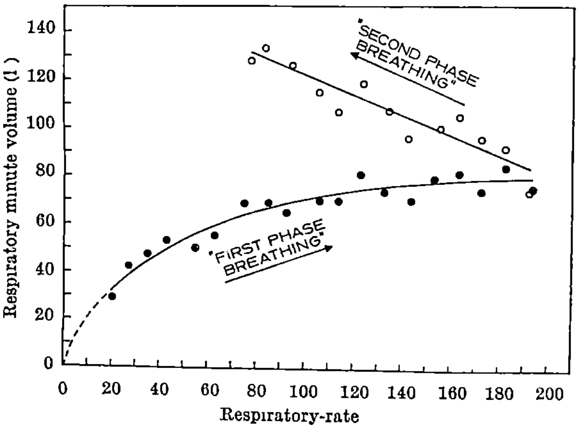

Fig 2 Relation between respiratory-rate and respiratory minute volume of calves exposed to an atmosphere of 40° C dry-bulb and 38° C wet-bulb temperature (Mean results for 8 animals)

man and Andersen[4] obtained under less stressful environmental conditions in cows, and it confirms their contention that a high respiratory activity is an attempted compensation for a poor heat balance brought about by some other cause

The inverse relationship between heat tolerance and respiratory minute volume gave rise to the question whether it would be possible to use respiratory-rate (which is easily determined) as an indicator of respiratory minute volume (which is less easily determined) The relationship of these two variables in severely heat-stressed calves is shown in Fig 2 Owing to the bi-phasic behaviour of respiratory-rate[5,6], in the higher range, a given respiratory-rate is associated with two different values of minute volume a lower minute volume during the rising phase ('first phase breathing'), and a higher one during the declining phase ('second phase breathing') Respiratory-rate cannot, therefore, be used to predict respiratory minute volume unless the 'phase' of respiration is known

Failure of Amino-nucleoside to produce Abnormalities in the Fœtus of the Rat

IN an experimental study of urinary tract malformations, an attempt is being made in our laboratory to influence with chemical agents the embryonic development of the kidney One substance that has been used is the amino-nucleoside derivative of 'Puromycin(R)', which is known to produce increased albuminuria and the nephrotic syndrome in rats Hallman *et al*[1] have used this substance in attempts to induce a congenital nephrotic syndrome in experimental animals, and they have described renal tubular dilatation in some offspring of rats treated during the last days of pregnancy

The test animals used were pregnant albino rats of the Sprague–Dawley strain, weighing 150–200 g Fifty-one animals were given amino-nucleoside for periods of 7 days, beginning on the fifth to fourteenth day of gestation Each course of treatment consisted of daily subcutaneous injections of 0 3 ml per 100 g of body-weight of one of the following solutions of amino-nucleoside in sterile distilled water 0 375 mg per 100 ml , 0 50 mg per 100 ml , 0 675 mg per 100 ml , and 0 750 mg per 100 ml (Table 1) Control animals were injected with sterile distilled water Offspring were killed at intervals up to 2 months after birth and their kidneys were examined histologically Available sera from offspring were pooled according to litters to make 17 batches, which were examined electrophoretically by the method of Smithies[2] Parent animals were also killed and examined in a similar fashion

* No of mothers
† No of offspring examined
‡ No of abortion sites

The highest dosage of amino-nucleoside caused abortion, as determined by the examination of the uterine implantation sites, in most animals Examination of the 170 living offspring in the experiment disclosed no gross malformations or microscopic abnormalities of the kidneys, and the electrophoretic patterns of serum proteins were normal No other anomalies were observed Eight parent animals which were treated with amino-nucleoside solution in a concentration of 0 5 mg per 100 ml did, however, develop microscopic renal abnormalities consisting of variable tubular dilatation, with proteinaceous precipitates and cast formation Five of these eight also had electrophoretic patterns of serum protein consistent with the nephrotic syndrome

These investigations have not produced congenital or developmental abnormalities in the kidneys of rats, and we have not been able to reproduce the findings of Hallman *et al* That the amino-nucleoside either produced abortion or left the fœtus unaffected, according to the dosage used, suggests that its toxic effect may have been mediated through interference with placental function

This work was supported by funds from the Michigan Kidney Disease Foundation and by research grant *A*-4418 from the National Institute of Arthritis and Metabolic Diseases, U S Public Health Service We also thank the Lederle Laboratories, American Cyanamid Co , Pearl River, New York, for providing samples of amino-nucleoside

Luteotrophic Activity of Human Growth Hormone (Raben)

I HAVE developed an assay for the measurement of luteotrophin in hypophysectomized adult mice which depends on the increase in the weight of a damaged horn of the uterus (formation of deciduomata) Mice were hypophysectomized on the first day of diœstrus and 48 h later the endometrium of the right horn of the uterus was injured The animals were injected daily for 5 days with a preparation of luteotrophin commencing immediately after hypophysectomy and killed on the sixth day The response was recorded as positive if the weight of the damaged horn was at least 11 mg greater than the weight of the control horn The results were expressed as the percentage of animals with a positive response and a probit transformation was used for parallel line assays Details of this method will be published shortly

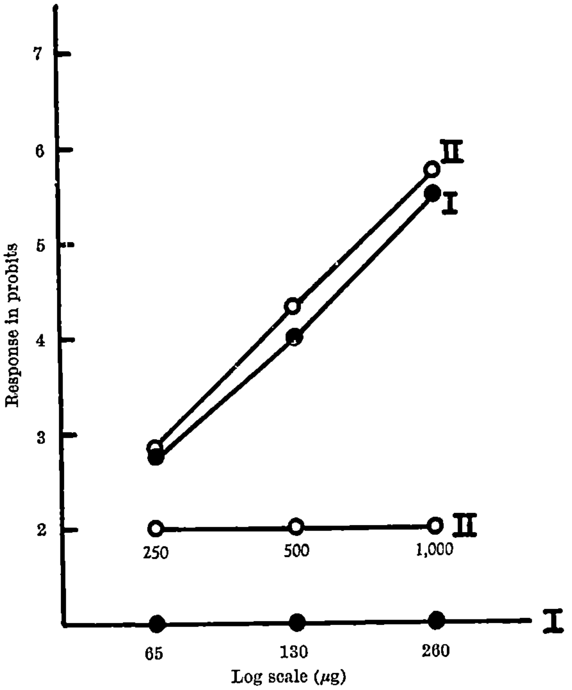

Fig 1 Dose-response curves of human pituitary growth hormone and of bovine prolactin I, bovine prolactin, Armour Laboratories, Lot No *D* 14083-2*B*, II, human pituitary growth hormone (Raben)

Human growth hormone prepared by the Raben method gave the same effect in hypophysectomized mice as the bovine prolactin, Armour Laboratories, Lot No *D* 14083-2*B* (assumed potency, 20 I U /mg) In positive responses the difference in weight between the two horns varied from 14 5 mg to 37 4 mg with human growth hormone and from 14 7 mg to 70 mg with bovine prolactin The doses for human growth hormone were 250, 500 and 1,000 μg per animal and for the bovine prolactin 65, 130 and 260 μg The potency of human growth hormone was 29 per cent (95 per cent fiducial limits 17–51) of the reference substance The results are given in Table 1 and Fig 1 These figures are in keeping with those previously obtained by the diœstrus method[1] and are of the same order as the results published by Ferguson and Wallace[2]

Table 1. RESULTS OF AN ASSAY OF HUMAN PITUITARY GROWTH HORMONE USING THE ARMOUR PROLACTIN LOT NO *D* 14083–2*B* (BOVINE) AS A STANDARD

A Physiological Basis for the 'Optimum' Level of Energy Expenditure

THE level of oxygen consumption, compared with the maximum intake, at which an individual can work safely for 6–8 h, from month to month, has been variously defined The Max Planck Arbeitsphysiologie Institute group in Dortmund support the idea that the rate of oxygen intake equivalent to the "Pulsdauerleistungsgrenze" (a heart-rate of about 120 beats/min) is the safe limit The sole basis of this criterion is that, in their experience, the heart-rate continues to rise and does not remain in a steady state when the level of oxygen consumption has caused the heart-rate to exceed 120 beats/min The "Pulsdauerleistungsgrenze" is said to occur at about 30 per cent of the individual's maximum level of oxygen intake[1] Christensen *et al* [2] have a sounder, even if empirical, basis for their safe limit They found that men engaged on hard manual work, such as lumberjacking, on high financial incentives, do not, in general, work at a level which exceeds 50 per cent of the maximum level of oxygen intake

Neither of these criteria has a real physiological basis An objective and sound physiological basis for the optimum level of work would be the level of oxygen consumption, compared with the maximum oxygen intake, at which the rate of supply of oxygen by cardio-respiratory mechanisms to working muscles no longer balances the rate of expenditure of energy, and anaerobic metabolism commences in working muscles Increase in blood lactate, alone, is not a reliable index of anaerobic metabolism, Huckabee has demonstrated that 'excess' lactate, derived from the ratio of total-body lactate to pyruvate, is the only reliable measure of anaerobic metabolism[3] This communication deals with the level of oxygen intake, compared with the maximum, at which 'excess' lactate appears in 6 young Bantu males highly trained on a bicycle ergometer

These subjects were tested at work-levels from 2,000 ft lb /min to 11,000 ft lb /min on a bicycle

Table 1

Mean							1 83	3 33	55 3

ergometer, working for 7 min at lower levels of work and for 5 min above 9,000 ft lb /min Measurements of oxygen intake and blood pyruvate and lactate were repeated on 4 separate occasions at each work-level Blood samples were analysed for lactate by the method of Barker and Summerson[4] as modified by Hullin and Noble[5] and for pyruvate by the method of Friedemann and Haugen[6] Huckabee's equation was used for calculating 'excess' lactate Maximum oxygen intakes were determined by working the men up to their individual maximal efforts, which in all cases were above 11,000 ft lb /min

Representative values of oxygen intake (means of 4 measurements) are plotted against work-rates (WR) for one subject in Fig 1, and those for 'excess' lactate plotted against work-rate in Fig 2 Appropriate straight lines are fitted by least squares A derived curve of excess lactate against oxygen intake is given in Fig 3 and illustrates the point at which excess lactate increases sharply A similar procedure was used for the other 5 subjects to determine for each individual the level of oxygen intake at which 'excess' lactate increases Confidence limits have not been determined for the present estimated curves because the scatter of values about the mean is relatively wide, and insufficient values have been obtained at the turning point to justify the procedure of fitting confidence limits A further experiment is planned for this purpose The parameters of the equation for the various curves is given in Table 1 for the 6 subjects together with the level of oxygen intake at which excess lactate began to increase, the maximum oxygen intake of the subjects and the percentage of the maximum at which 'excess' lactate occurs The average of this last item for the six subjects is 55 3 per cent

It appears then that men who are highly trained, at both aerobic (or endurance work) and anaerobic oxygen intakes, can work to a level of about 55 per cent of their maximum oxygen intakes without anaerobic metabolism occurring in the body This percentage is in excess of the levels based on the previous criteria, which have no sound physiological basis, and may be due to the fact that these men were so highly trained Also it may well be that even under high financial incentives, men do not 'will' themselves in ordinary industrial situations to work at the optimum level of which they are capable The application of Huckabee's 'excess' lactate concept to the level of oxygen intake at which anaerobic metabolism occurs, compared with the maximum level of oxygen intake, opens the way to study objectively these two problems and many others which bear both

PHARMACOLOGY

Antagonism of Bretylium by Sympathomimetic Amines

BRETYLIUM, an antihypertensive agent, inhibits the function of the adrenergic nerves without antagonizing the actions of epinephrine and *nor*epinephrine[1] It appears that bretylium blocks the terminal portion of the post-ganglionic sympathetic fibre by preventing the release of the neurohumoral agent Bretylium should then block the effects of certain agents which cause the release of the transmitter substance from the terminals of the sympathetic post-ganglionic fibres According to Burn and Rand[2], such sympathomimetic amines as amphetamine, ephedrine, tyramine and phenylethylamine elicit their action by releasing the neuro-humoral agent from the terminals of the nerve fibres However, Hukovic[3] and Azarnoff and Burn[4] have reported that the actions of tyramine are potentiated in isolated atrial preparations after pretreatment with bretylium

Cocaine is known to antagonize the actions of *TM*10 (ref 5) and bretylium[1] According to Wilson and Lang[6], the hypotensive effects of bretylium are not seen in hypertensive patients receiving amphetamine Although cocaine and amphetamine are dissimilar chemically, they do possess certain pharmacological properties in common One property exhibited by both compounds is the ability to potentiate the actions of the catecholamines, presumably by preventing their uptake by tissue[7] In this communication we record preliminary experiments on the interactions of bretylium and some agents that are known to possess this property

Cats of either sex, weighing 2–3 kg, were used in this work Pentobarbital, 30 mg/kg intraperitoneally, was used for anæsthesia and supplemental amounts were given intravenously as required The blood pressure was measured from the femoral artery using a Statham pressure transducer and a Gilson macropolygraph Contractions of the nictitating membrane were measured with a Grass strain gauge (Model *FT* 0 03) and a Gilson macropolygraph A tension of 5 gm was placed on the membrane All drugs were prepared in saline and injected into the femoral vein

The following drugs were used *dl*-amphetamine sulphate (350 μg/kg), tyramine hydrochloride (350 μg/kg), phenylethylamine (350 μg/kg), ephedrine (350 μg/kg), deoxyephedrine (300 μg/kg), bretylium (15 mg/kg in three divided doses) and imipramine (20 mg/kg intraperitoneal)

The general pattern of the experiments was as follows Control responses to nerve stimulation were obtained The stimulus used was a square wave of 7 V, 2 msec duration, 25/sec for 5 sec This was followed by the administration of the respective drug under study After an appropriate period of time following the drug, usually 5 min, bretylium was given

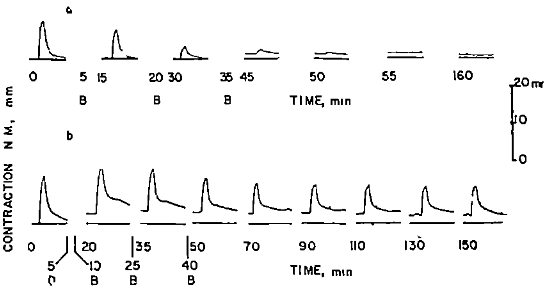

Fig 1 *a*, Response of nictitating membrane to nerve stimulation At times indicated by *B*, bretylium (5 mg/kg) was given Black dot indicates initial point of stimulus *b*, Responses of nictitating membrane to nerve stimulation At *D*, deoxyephedrine (350 μg/kg) was given, at *B*, bretylium (5 mg/kg) was given

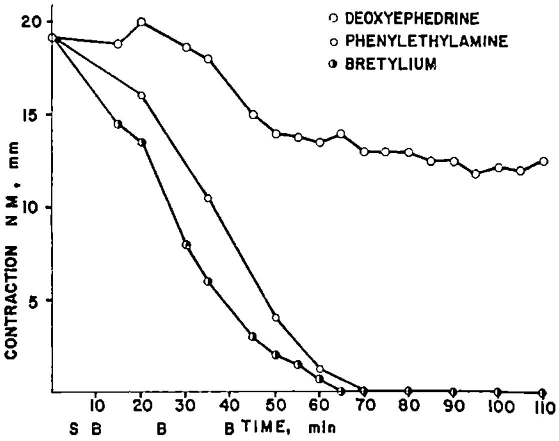

Fig 2 Response of nictitating membrane to nerve stimulation At *S*, sympathomimetic amine (350 μg/kg either deoxyephedrine or phenylethylamine) was given, at *B*, bretylium (5 mg/kg) was given Three animals were used with each drug

After bretylium, the nictitating membrane failed to respond to the stimulation of the sympathetic cervical nerve (Fig 1*a*) The effects of bretylium were apparent after the first administration, however, complete blockade did not occur until approximately 20 min after the last administration of bretylium This block was long lasting, in one experiment the block continued for 4 h, at which time the experiment was terminated In cases where bretylium was preceded by deoxyephedrine, the nictitating membrane did not show failure to nerve stimulation (Fig 1*b*) Although the response was diminished slightly after bretylium, it never demonstrated complete failure of response during the period of experimentation (up to 4 h) The other long-lasting sympathomimetic amines, amphetamine and ephedrine, also prevented the action of bretylium on the cervical nerve Imipramine, an antidepressant drug, also antagonized the actions of bretylium in a manner qualitatively similar to deoxyephedrine The short acting sympathomimetic drug, phenylethylamine, did not antagonize the action of bretylium on the cervical nerve (Fig 2) The response to nerve stimulation showed failure approximately 20 min after the last administration of bretylium This was similar to those experiments which received only bretylium Although it is not shown here, tyramine possessed properties that were qualitatively similar to phenylethylamine.

The antagonism of bretylium displayed by the long-acting sympathomimetic amines and imipramine may be explained by their common property, that is, the potentiation of catecholamines by the inhibition of their uptake by tissues. It is possible that during blockade of cervical nerve stimulation, bretylium allows only sub-threshold amounts of norepinephrine to be released. The agents that do antagonize bretylium may do so by preventing the tissue uptake of the subliminal amounts of norepinephrine released during stimulation. This would allow the concentration of norepinephrine to reach threshold levels, resulting in the contraction of the effector organ.

Hertting *et al.*[7] have shown that tyramine will also inhibit the tissue uptake of norepinephrine. The inability of tyramine to antagonize bretylium in our experiments may be explained on the basis of the differences in dosage. It is possible that, with higher doses, tyramine will also antagonize bretylium.

An alternative explanation for the antagonism of bretylium may be the competition for receptor sites on the terminal of the nerve. It is possible that the sympathomimetic amines and bretylium may occupy identical receptors or those in close juxtaposition. The long lasting amine may have a greater affinity for the receptor than bretylium. On the other hand, the short lasting amines occupy the receptor for a short time, allowing bretylium to act upon the terminals and resulting in blockade. However, the actions of imipramine cannot be explained on this basis. Since it potentiates the actions of catecholamines, the first explanation appears more tenable.

Further experiments are being carried out in this laboratory on the role of the inhibition of tissue uptake of norepinephrine as the possible mode of action of the antagonism of bretylium.

This work was supported in part by the U.S. Public Health Service pharmacology training grant (2*G*-109 (*C*2)). We thank Dr. S. T. Bloomfield of Burroughs Wellcome and Co., Inc., Tuckahoe, New York, for supplying the bretylium tosylate.

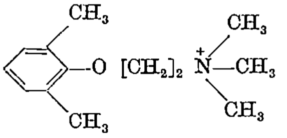
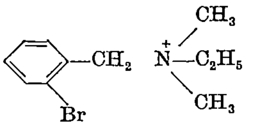
Amidines as Adrenergic Neurone Blocking Agents

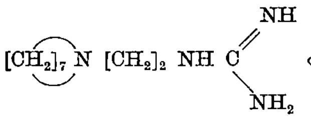
2,6-Xylylether bromide (I), bretylium (II) and guanethidine (III) cause several similar adrenergic neurone blocking effects. The finding of similar properties in the benzyl- and phenoxy-ethylguanidines (IV), (V) and (VI) supported the view that quaternary ammonium and guanidine groups might have similar influences on pharmacological action[1]. These compounds are strongly basic and almost completely ionized at physiological *p*H values. It was therefore of interest to examine the compounds (VII) wherein high basicity was conferred by an amidine group. Several of these compounds showed powerful adrenergic neurone blocking properties, one of the most potent being *N*-[2-(hexahydro-1-azepinyl)ethyl]acetamidine (VII: $n=6$, $m=2$, $R=CH_3$) (*BW* 1113*C*60), which was prepared and tested as a stable non-deliquescent dihydrochloride[2].



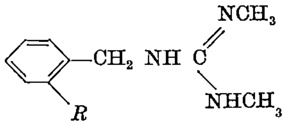
I



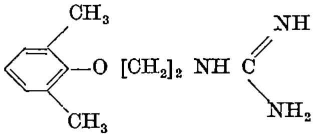
II



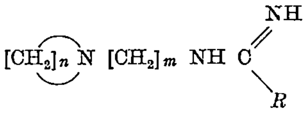
III



IV $R = H$
V $R = Cl$



VI



VII

In unanæsthetized cats, the dose of *BW* 1113*C*60 dihydrochloride required to relax the nictitating membranes was similar to that of guanethidine (3–10 mg/kg subcutaneously), but threshold doses of the compound administered daily for a week showed less cumulative action. In anæsthetized cats, intravenous doses of 1–3 mg/kg blocked responses of the nictitating membrane to postganglionic sympathetic nerve stimulation and showed a variety of other adrenergic neurone blocking effects. Experiments with nerves stimulated at different frequencies showed that the responses to low rates of stimulation were preferentially suppressed and that the curve relating the log frequency of stimulation and the nictitating membrane contraction was shifted to the right without depression of slope. This change is similar to that seen after guanethidine[3] and is distinct from that with bretylium, which depresses the slope of the response curve without first suppressing the effects of low stimulation frequencies[4]. Guanethidine, in contrast to bretylium, lowers the concentration of catechol amines in tissues with a rich adrenergic nerve supply, this depletion occurring after the blockade of the adrenergic nerves[5]. That the effect of *BW* 1113*C*60 on catechol amine stores may resemble that of guanethidine is suggested by the finding that the pressor amine content of the iris of cats was found to be reduced 24 h after subcutaneous injection of 10 mg/kg of either of these compounds. *BW* 1113*C*60 also showed prominent sympathomimetic effects resembling those of guanethidine and, similarly, large intravenous doses caused brief blockade of transmission in autonomic ganglia and neuromuscular junctions of voluntary muscle.

Comparison with related compounds in unanæsthetized cats showed that, as in the guanethidine series[6], the presence of a large heterocyclic ring was essential to high adrenergic neurone blocking activity, but in the present series of compounds the seven-membered ring produced the highest potency. Among compounds containing this ring, *BW* 1113*C*60 was more active than its homologue *N*-[3-(hexahydro-1-azepinyl) propyl]acetamidine (VII, $n=6$, $m=3$, $R=CH_3$), which in turn was more active than the propionamidine (VII, $n=6$, $m=2$, $R=C_2H_5$), and the formamidine (VII, $n=6$, $m=2$, $R=H$) (Repeated preparations of the formamidine gave poor elementary analyses, but its structure was supported by electrometric titration data provided by Dr A J Everett) The acyclic compound, *N*-(2-dipropylaminoethyl) acetamidine, was also relatively inactive

HÆMATOLOGY

Effects of Corticosteroids on Coagulation of the Blood

Hypercoagulability of the blood in individuals who were receiving large doses of corticosteroids or adrenocorticotrophic hormone (ACTH) has been observed[1–3] This effect has also been observed in patients receiving ACTH for cirrhosis of the liver[4], a condition that usually depresses certain clotting factors For investigation of this problem heparin and antithrombic activity were evaluated, fibrinogen level and platelet counts were determined[1,4] Shortening of the clotting time was the most consistent coagulation finding in persons who were on corticosteroid or ACTH[1,4] The effect has been observed, particularly in siliconized tubes, in as little as 2–4 h after administration of 10 mg of prednisone[5,6] This effect was somewhat less marked after administration of 25–50 units of ACTH[5,6]

In the present investigations the following coagulation tests have been used Quick time[7], partial thromboplastin time[8], assays of prothrombin[9], factor V[9], and factor VII–X[9], thromboplastin generation test[10], assay of antihæmophilic factor[11], and fibrinogen[12]

We had the opportunity to perform coagulation investigations in a patient with Cushing's syndrome due to bilateral adrenal hyperplasia The Quick time of 9 2 sec (normal range 12–15 sec), partial thromboplastin time of 65 sec (normal range 60–100 sec), and minimum substrate clotting time in thromboplastin generation test of 9 0 sec (normal 9–11 sec) were unusually short The antihæmophilic factor-level of 420 per cent was quite high (normal range 50–200 per cent) The other coagulation tests were in the normal range Coagulation studies repeated 14 days after bilateral adrenalectomy, while the patient was maintained on 'Decadron' 2 mg and fluorohydrocortisone 0 1 mg daily, revealed a reversion to normal values (Quick time 13 2 sec, partial thromboplastin time 71 sec, minimum substrate clotting time in thromboplastin generation test 10 sec, antihæmophilic factor 110 per cent)

In vitro studies were carried out by adding prednisone in various concentrations to the patient's preoperative plasma and normal plasma and performing the Quick time and partial thromboplastin time on these mixtures No differences, compared to the normal saline controls, were observed

Coagulation studies were performed on four patients who had been on prednisone 60 mg a day for at least 10 days Three of these patients had rheumatic fever with carditis and one patient had idiopathic thrombocytopænic purpura Their ages ranged from 9 to 13 years Shortened Quick times ranging from 10 4 to 12 2 sec, short partial thromboplastin times ranging from 57 to 65 sec and short minimum substrate clotting times in the thromboplastin generation test ranging from 8 to 9 sec were noted Antihæmophilic factor-levels measured in the three patients with rheumatic heart disease ranged from 200 to 260 per cent In one of these, factors V, and VII–X were also slightly elevated (170 and 190 per cent respectively with normal range of 60–120 per cent) and in the other two, fibrinogen-levels were 460 and 504 mg per cent respectively (normal 200–400 mg per cent)

A 13-year-old patient with idiopathic thrombocytopænic purpura and a 7-year-old patient with rheumatic heart disease were examined before as well as 3 days after institution of oral prednisone, 60 mg daily Shortening of Quick time and partial thromboplastin time, as well as a rise of antihæmophilic factor (from 125 to 250 per cent and from 160 to 200 per cent respectively), were noted

The effect of corticosteroids on three patients with classic hæmophilia was then examined (Table 1) They were placed on prednisone 60 mg a day in 4 divided doses for 7 days Coagulation data were obtained before the medication was started, after 7 days of administration, and one week after the drug was discontinued

Table 1 Prednisone Effect on Classic Hæmophilia (severe, moderately severe and mild)

		Severe hæmophiliac aged 13 years			Moderate hæmophiliac aged 10 years			Mild hæmophiliac aged 12 years		
	Normal	Pre-steroid	1 week steroid treatment	1 week off steroid	Pre-steroid	1 week steroid treatment	1 week off steroid	Pre-steroid	1 week steroid treatment	1 week off steroid
Quick time	12–15 sec	13 6	13 0	13 2	13 5	12 5	13 5	13 0	11 2	11 2
Partial thromboplastin time	60–100 sec	237	89	300	174	106	218	94	95	95
Prothrombin	60–120%	48	100	180	76	110	82	74	72	80
Factor V	60–120%	63	83	60	68	76	90	58	40	38
Factor VII–X	60–120%	55	100	78	68	95	64	97	94	94
Antihæmophilic factor	50–200%	<1	<1	<1	2 5	5 2	1 6	7	13	7
Fibrinogen	200–400 mg %	254	257	270	284	282	294	—	230	200

In the severely affected patient, although the antihæmophilic factor level did not rise above 1 per cent of normal, the partial thromboplastin time decreased to normal range after one week of treatment There was a moderate rise of prothrombin, factor V, and factors VII–X One week after cessation of treatment, the partial thromboplastin time was back to the original value

In the moderately severe classic hæmophiliac under the same treatment, the antihæmophilic factor-level gradually increased over a week's period from 2 5 to 5 per cent with a disproportionate shortening of the partial thromboplastin time and some shortening of Quick time A week after cessation of treatment, these findings returned to original values

In the mild case of classic hæmophilia under corticosteroid treatment the antihæmophilic factor-level almost doubled from 7 to 13 per cent

These preliminary results seem to indicate that the antihæmophilic factor-level increases considerably in individuals under treatment with high doses of corticosteroids This rise occurs both in non-hæmophiliacs and in moderately or mildly affected classic hæmophiliacs Shortening of the Quick time in some of the steroid-treated individuals without concomitant rises in the coagulation factors of the second stage and in particular the disproportionate shortening of the partial thromboplastin time in the treated hæmophiliacs suggests that corticosteroids have some clot-promoting effect apart from raising the level of antihæmophilic factor The nature of this other clot-promoting principle is not elucidated

Absence of Hæmoglobin A_2 in an Adult

HÆMOGLOBIN A_2, the minor component of normal adult hæmoglobin, amounts to about 2 5 per cent of the total hæmoglobin, it can be distinguished from the major adult component, hæmoglobin A_1, by its electrophoretic and chromatographic properties

Recent investigations have shown that hæmoglobin A_2 consists of two types of polypeptide chains the α-chain, identical with the α-chain of hæmoglobins A_1 and F, and the δ-chain, which differs in constitution from the corresponding chains of hæmoglobin A_1 (the β-chain) and F (the γ-chain)[1,2] A two-fold increase of the normal percentage of hæmoglobin A_2 occurs in the usual type of β-chain thalassæmia trait, prevalent in Greece[3], while a decrease is observed in hæmoglobin-H disease A decrease of the A_2 fraction down to 1 per cent has been observed as a reversible phenomenon in iron-deficiency anæmia[4] Traces of hæmoglobin A_2 can be detected in cord blood hæmoglobin by the application of special techniques

Qualitative alterations of hæmoglobin A_2 have been reported in a few cases[5,6], these, similarly to the variants of the hæmoglobins A_1 and F, are considered variants of hæmoglobin A_2

We wish to report the complete absence of hæmoglobin A_2 in a 60-year-old man, he belongs to a family several members of which carry a β-chain thalassæmia trait unassociated with an elevated hæmoglobin A_2 He had been subjected to gastrectomy three months previously, but there was no history of loss of blood The laboratory findings (hæmoglobin 11 2 gm /100 ml, red cells 6,500,000/mm ^{3}, volume of packed red cells 37 5 per cent, pronounced microcytosis and poikilocytosis, moderate hypochromia, serum iron 90 μgm /100 ml) were typical of thalassæmia trait Hæmoglobin electrophoresis disclosed the presence of hæmoglobin A_1 only, hæmoglobin F amounted to 2 5 per cent

The complete absence of hæmoglobin A_2 was repeatedly demonstrated in this case on samples taken at intervals prior to, and also after, intravenous treatment with iron Starch-gel electrophoresis and agar electrophoresis at *p*H 8 4, in conjunction with intense benzidine staining, were used to demonstrate the absence of A_2 (Fig 1) Hæmoglobin solutions from a normal adult containing a low percentage of hæmoglobin A_2 (1 5 per cent) were diluted serially and run simultaneously as controls The hæmoglobin A_2 fraction was well demonstrated in the 100-fold dilution of the control sample, which corresponds to a percentage of 0 015 A_2 in an undiluted sample Absence of a band corresponding either to normal or abnormal A_2 fraction was also noted by chromatography on 'Amberlite *IRC*–50' and by starch block electrophoresis

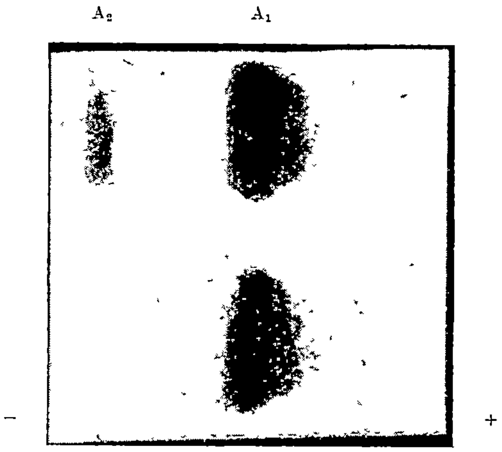

Fig 1 Starch-gel electrophoresis, discontinuous buffer system at *p*H 8 4, benzidine stain Above, normal adult control, below, sample lacking hæmoglobin A_2

Among this individual's offspring from an entirely normal wife, there were both normal persons and persons with thalassæmia trait, all having a percentage of hæmoglobin A_2 within normal limits, none displayed complete absence of hæmoglobin A_2

Present-day evidence indicates that the synthesis of the δ-chain is under separate genetic control[2], the genes for β-chains and δ-chains being probably linked[5] Absence of normal hæmoglobin A_2 is expected to occur in individuals homozygous for an electrophoretically detectable α-chain or δ-chain variant, in these cases, the variant hæmoglobin replaces normal A_2[6,7] Complete absence of A_2 has been further observed in a case of homozygosity for hæmoglobin 'Pylos'[8] In the case under discussion, no evidence was obtained that another component had replaced hæmoglobin A_2

So far as we are aware, this is the first observation of an adult having almost exclusively hæmoglobin A_1 and entirely lacking hæmoglobin A_2 In the light of the known disturbances in hæmoglobin synthesis, we assume that the complete inability of this individual to synthesize δ-chains is genetically determined On one hand, this person carries a type of thalassæmia affecting apparently the synthesis of both β- and δ-chains, such a type of abnormality, transmitted as a single gene defect, has been assumed to exist in certain cases of thalassæmia trait presenting normal percentage of A_2, observed elsewhere[9] as well as here[3,11] On the other hand, the complete absence of the A_2 fraction, while the offspring with thalassæmia trait presents normal percentage of A_2, make it necessary to assume that, in this particular case, an additional defect concerning the other δ-chain allele is also present

The possibility of the existence of a gene suppressing the synthesis of δ-chains has already been considered[8], the action of such a gene may be visualized as similar to the action of the known thalassæmia genes on either α- or β-genes[10] It is known that β-chain thalassæmia genes at least may lead to complete absence of β-chains[11,12] In the case described here, we assume that the genetic lesion causing suppression of both β- and δ-chains and leading to the hæmatological picture of thalassæmia trait is associated to a gene affecting solely δ-chain production, this results in failure to synthesize hæmoglobin A_2 Both healthy and thalassæmic offspring are expected to present hæmoglobin A_2, having of necessity inherited a normal δ-chain allele from the mother

In view of the fairly wide range of the normal A_2 values, persons heterozygous for such an isolated δ-chain anomaly (a δ-chain thalassæmia) may not easily be detected by quantitation of hæmoglobin A_2 Furthermore, the reduction or the complete absence of the small quota of the A_2 fraction may not be expected to give rise, *per se*, to alterations of the red cell morphology However, the simultaneous occurrence of such a gene and of the gene for typical (high A_2) β-chain thalassæmia in one person may prevent hæmoglobin A_2 from rising over normal values Should these two genes be in the coupling phase, their association is likely to manifest itself as a thalassæmia trait, without increased hæmoglobin A_2, transmitted as a single gene defect The possibility has to be considered that such may be the situation in some of the thalassæmia traits which are known to be β-chain thalassæmias but which do not present an elevated A_2 fraction

The complete absence of hæmoglobin A_2 in an individual carrying exclusively hæmoglobin A_1 provides further proof that hæmoglobin A_2 is not a by-product of the synthesis or catabolism of A_1

This investigation was supported by Research grant No *H*–4541 of the National Institutes of Health, U S Public Health Service

RADIOBIOLOGY

A Correlation between Radiation Tolerance and Nuclear Surface Area

FROM results of morphological investigations it was concluded[1] that the Feulgen-stained material in somatic cell nuclei is distributed peripherally and it was suggested that this peripheral zone consists of two concentric zones in close proximity Sparrow and Miksche's data[2] on a correlation of nuclear volume and DNA content with higher plant tolerance to chronic radiation seem to offer evidence that such distribution of nuclear DNA is also found in the living somatic plant cell

These investigators determined the dose (r /day) required to produce severe growth inhibition in 23 species of plants and found a linear relationship between the logarithm of the nuclear volume, the volume being taken as a measure of the DNA-content and determined by micrometry in 10μ thick sections, and the logarithm of the dose

They give data in their Table 1 for six species from which the following equations can be calculated

$$\log(\text{nuclear volume}) = 4\ 42 - 0\ 82 \log \text{dose} \qquad (1)$$

and

$$\log(\text{nuclear volume}) = 1\ 66 + 0\ 66 \log \text{DNA} \qquad (2)$$

where log DNA denotes the average nuclear DNA-content, determined by chemical extraction The photometrically determined DNA-content values given in Table 1 have been disregarded, as it has been demonstrated[3] that the product of absorbance and nuclear area is not a direct measure of mass

If all the nuclear DNA is distributed in two peripheral zones of such close proximity that the difference in surface area between the two zones is negligible and therefore each zonal surface area $\simeq$ nuclear surface area, we have from (2)

$$2(\log \text{nuclear surface area}) = 1\ 33(\log \text{nuclear volume}) = 2\ 21 + 0\ 88 \log \text{DNA} \qquad (3)$$

The numerical value of the slope is thus only 12 per cent lower than the expected value of 1·0. From eqv. (1)

$$2\,(\text{log nuclear surface area}) = 1{\cdot}33\,(\text{log nuclear volume}) = 5{\cdot}88 - 1{\cdot}09 \text{ log dose} \quad (4)$$

The value of the slope in (4) is also lower—by 9 per cent—than the expected value of 1·0. When considering the very small numbers of experimental observations and considering that the deviations are both in the same direction and of the same magnitude, the agreement is remarkably good.

For the 23 species, Sparrow and Miksche found

$$\text{log nuclear volume} = 4{\cdot}07 - 0{\cdot}73 \text{ log dose} \quad (5)$$

from which we obtain

$$2\,(\text{log nuclear surface area}) = 5{\cdot}41 - 0{\cdot}97 \text{ log dose} \quad (6)$$

where the value of the slope is as near the theoretical value of 1·0 as can be expected. This demonstrates that the product of log surface area and log dose is constant, and indicates that each zone is equally sensitive towards radiation and implies that each (diploid) interphase nucleus for the greater part of this period carries a DNA-charge of $2 \times 2n$.

Effect of Radiation on the Electrophoretic Mobility of Ehrlich Ascites Tumour Cells

STEIN *et al.*[1] have shown that low doses of radiation cause a small increase in the negative electrophoretic mobility of Ehrlich ascites tumour cells.

In the course of our investigations of the effect of X-irradiation on Ehrlich ascites tumour cells we have measured the electrophoretic mobility of tumour cells withdrawn from *C3H* mice (for source, see ref. 2). Nine days after implantation of the tumour the animals were given a whole-body dose of 1,400 rads at a rate of 350 rads/min and killed 24 h later. After withdrawal from the mouse, the tumour cells were washed three times in 0·145 N sodium chloride, prior to a determination of the electrophoretic mobility (for method, see ref. 3).

An experiment involved determining the mobility of tumour cells removed from one irradiated mouse and one control mouse (that is, not irradiated). The electrophoretic mobility of cells withdrawn from the same mouse was reproducible but considerable variation of mobility was shown with cells from different mice. Bangham *et al.*[4] have commented upon the range of mobility values observed for tumour cells from non-irradiated mice.

The negative electrophoretic mobility of tumour cells from irradiated mice and control mice is 1·39 ± 0·03 (*S.E.*) μ/sec/V/cm and 1·41 ± 0·04 (*S.E.*) μ/sec/V/cm respectively, the quoted mobilities are mean values obtained from the results of 19 experiments. Applying Student's *t* test to the distribution of results indicates that there is no significant difference between the two mean values. Hence, we must conclude that the radiation has no measurable effect on the electrophoretic mobility of the tumour cells.

A different source of tumour material giving rise to a different electrophoretic pattern may be the cause of the disparity between the results of our experiments and the observations previously reported[1].

We thank Dr. G. M. Bell and Dr. L. R. Shenton for discussion, Mr. D. Porteous for preparation of the irradiated mice, and the British Empire Cancer Campaign for a supporting grant to one of us (S. H.).

Dependence of Radiation Diarrhœa on the Presence of Bile in the Intestine

SYMPTOMS after exposure of the abdominal region of rats to X-radiation doses of 1,000 r., or greater, almost invariably include diarrhœa beginning at 3 days after X-ray irrespective of the dose. If death does not occur within the next 3 or 4 days there is a rapid improvement and the diarrhœa stops. Both the early onset and rapid improvement are usually attributed to the short turnover-time of the epithelial cells of the intestine. However, when the biliary flow was interrupted by ligation or cannulation of the common bile duct the incidental observation was made that diarrhœa did not occur[1,2].

Albino male rats weighing about 300 g were prepared by placing polythene cannulæ in the proximal duodenum and when necessary in the common bile duct. Then 2 days later the abdomina of these rats were exposed to 1,000 r. of 250 kV X-rays. When the bile was diverted from the lumen of the intestine by cannulation of the bile duct, diarrhœa did not develop even when a volume of isotonic saline equal to the volume of bile (15 ml./day) was administered intraduodenally (Table 1). However, in irradiated cannulated rats diarrhœa occurred as in unoperated controls, when bile was injected daily into the duodenum in quantities comparable to the normal daily output of bile. This occurred whether the bile had been collected from irradiated or non-irradiated rats. Diarrhœa also followed daily intraduodenal injections of bile salts (50 mg taurocholate or tauroglycocholate or 6 mg deoxycholate, each in 15 ml. of 0·9 per cent sodium chloride).

Table 1. INFLUENCE OF BILE ON DIARRHŒA INDUCED BY EXPOSURE OF THE ABDOMEN TO 1,000 R. OF X-RADIATION

Bile duct cannula	Injection into duodenum	Initial	No. of rats Diarrhœa at 3 and 4 days	Deaths at 7 days
No	Saline	10	10	8
Yes	Saline	19	1	16
Yes	Rat bile	8	8	7
Yes	Saline + bile salts	14	14	12

It is apparent from these results that the bile and, more specifically, the bile salts, are intimately involved in the development of radiation-induced diarrhœa, and that the diarrhœa cannot be due merely to a radiation-induced defect in the cellular turnover of the intestinal epithelium. Full details of these and other experiments to elucidate the mechanism by which bile salts act on the irradiated intestine will be reported later

Comparative X-ray Sensitivity of *Tribolium confusum* and *T. castaneum* (Coleoptera : Tenebrionidae) at Different Developmental Stages during their Life-cycle

THE X-ray sensitivities of two ecologically similar species of flour beetles, *Tribolium confusum* (Chicago 'Standard' strain) and *Tribolium castaneum* (Brazil *C*I strain), were compared at eight different ages which span the life-cycle

The X-ray was delivered at 1 kr /min by a General Electric Maxitron generator operated at 30 m amp, 250 kV, 0 25 mm copper + 1 0 mm aluminium filtration and a 2 5 in anode-subject distance Below 10 kr , doses were given in 0 5 kr increments, while higher doses were given in 10 kr increments Groups of 50–100 individuals per life-cycle stage were exposed at each dose Culture conditions were 29 ± 2 C and 70 ± 10 per cent relative humidity

A dose was assumed to induce sterility if no progeny developed, and lethality if exposed individuals failed to mature into adults or if they died within 3–4 weeks after eclosion

The radiosensitivities for both species are compared in Fig 1 The egg (1–3 h after oviposition) was the most radiosensitive stage At this highly mitotic period, 1–2 kr was lethal In subsequent life-cycle stages, lethal doses were higher than sterilizing doses *T confusum* was consistently more X-ray sensitive than *T castaneum* Radiation sensitivity remained more or less constant during the larval stages except the tolerance of *T castaneum* decreased at the 15-day old larval stage The marked radioresistance in terms of lethality of *T castaneum* pupæ persisted through adulthood Young pupæ of *T confusum* were less radioresistant than old pupæ or adults

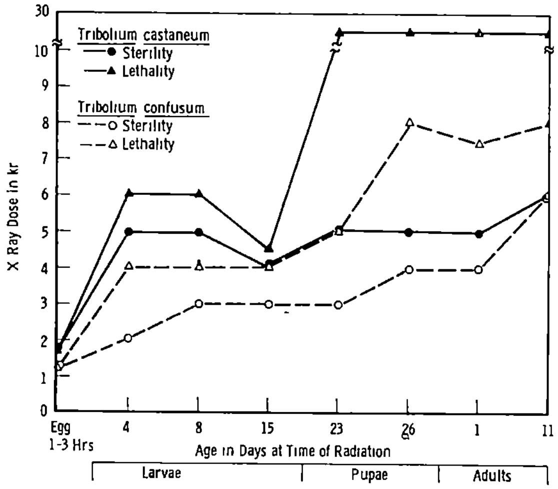

Fig 1 Comparative sterilizing and lethal X-ray doses at various development stages in the life-cycles of *Tribolium confusum* and *T castaneum*

The differential radiosensitivity of gametes in adults (more sensitive in 1 than in 11-day old adults) corroborates Dick's histological observation[1] that *T confusum* females were not sexually mature until the fourth or fifth day of adult life A differential radiation response of reproductive tissues was also observed in *Habrobracon*[2–4] and *Drosophila*[5]

Experiments are planned to explain the species differences in response to radiation Perhaps the one more pair of autosomal chromosomes in *T castaneum*[6], nuclear volumes, DNA contents, oxygen consumptions, or specific chromosomal (genic) sensitivities, contribute to the differential radiotolerances between these species of flour beetles

Relations between Day-length and Annual Patterns of Plant Development

THE relatively unchanging annual sequence of anthesis of plant species which occurs naturally each year could be explained in terms of a primary effect of light duration with which secondary factors such as temperature and rainfall interact, provided all species were sensitive to the effects of light duration with respect to anthesis, that is, if there were no completely day-neutral plants

The tomato (*Lycopersicum esculentum*) has long been regarded as a typical day-neutral plant with respect to flowering Results from work at this Institute suggest that there is a hyperbolic relation between day-length and the age of the tomato at first anthesis of the form shown in Fig 1 by the continuous line, the longer the day-length the younger the plant at anthesis This would suggest that the tomato is basically a weak long-day plant, and that it is not day-neutral The interaction of a hyperbolic response curve of this type with the parabolic curve of annual variation in day-length at the latitude of the Institute would mathematically produce an annual pattern of age at anthesis of the skew form shown in Fig 2 by the continuous line The mathematically derived curve was found to correspond with the experimentally determined annual pattern of anthesis I thank my colleague, Mr D Cooke, for the calculation of the curves in Fig 1 and 2

By recalculation of the data on the anthesis of kenaf (*Hibiscus cannabinus*) collected by Walker, Sierra, Bedia and Hopp[1] it can be shown that there is a hyperbolic relation between day-length and the age of kenaf at anthesis of the form shown in Fig 1 by the broken line, the shorter the day-length the

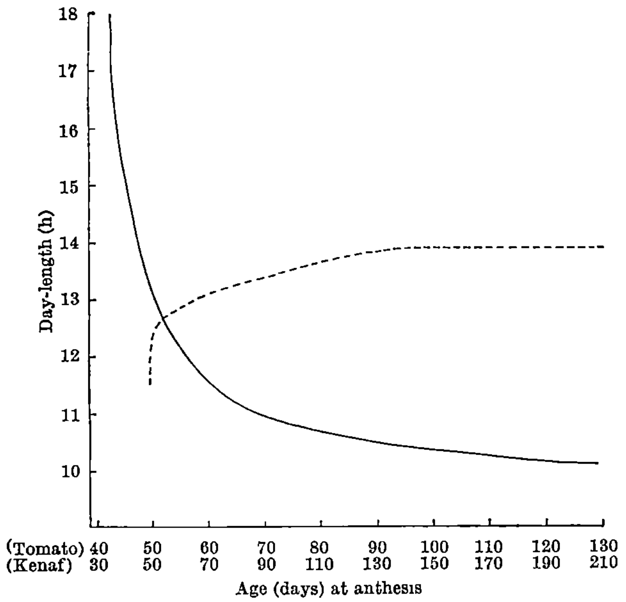

Fig 1 Relation between age at anthesis and day-length

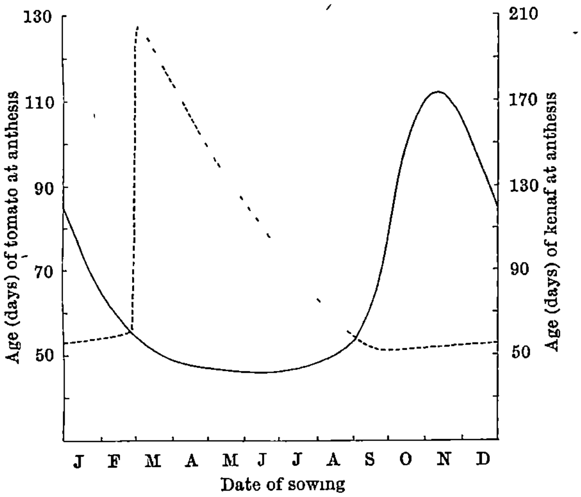

Fig 2 Seasonal patterns of the age at anthesis for tomato and kenaf

younger the plant at anthesis This would suggest that kenaf is basically a short-day plant with respect to anthesis The interaction of a hyperbolic response curve of this type with the parabolic curve of annual variation in day-length at the latitude of Santiago de las Vegas, Cuba, produces an annual pattern of age at anthesis of the skew form shown in Fig 2 by the broken line Each of the curves in Figs 1 and 2 are defined by 52 points and relate to weekly sowings in natural daylight at the two places concerned

These data suggest that there may be no completely day-neutral plants, but that apparently day-neutral plants may be included in two main groups of (*a*) long-day plants with hyperbolic response curves of the form shown by the continuous line in Fig 1; (*b*) short-day plants with hyperbolic response curves of the form shown by the broken line in Fig 1 The degree of sensitivity to day-length would be determined by the equation of the response curve For the long-day group the higher the value of the day-length asymptote the more sharply defined would be the long-day response, the lower the value the less sharply defined the long-day response For the short-day group the lower the value of the day-length asymptote the more sharply defined would be the short-day response, the higher the value the less sharply defined the short-day response Thus apparently day-neutral plants would be basically either long-day plants with low day-length asymptotes or short-day plants with high day-length asymptotes, and there would be two continuous series of species ranging from strongly short-day (or long-day) to weakly short-day (or long-day)

The interaction of these two continuous series of hyperbolic day-length responses with the parabolic annual variation in day-length at a given latitude would primarily determine the unchanging annual sequence of anthesis of plant species at that latitude, although other factors such as temperature and rainfall would interact with the hyperbolic response curves

Effects of Coconut Milk and Kinetin on the Development of the Protonema and Bud Formation in *Pohlia nutans*

In previous experiments[1] on the effects of kinetin on the development of the protonema and the formation of shoot-buds in *Pohlia nutans* (Hedw) Lindb , it was found that buds were formed earlier in cultures containing kinetin and it seemed that in this respect its action was similar to red light[2] Buds were not produced on the protonema growing on a basal medium under blue light Since certain responses of higher plants to coconut milk are analogous to those induced by kinetin, for example, the induction of cell-division in mature tissue and the differentiation of a complete plant from a mass of such dividing cells, it seemed that it might be of interest to study the effects of coconut milk alone and in combination with kinetin on the development of the protonema and the initiation of shoot-buds in *Pohlia nutans*

Aseptic cultures were prepared from small protonema inocula on modified Voth's medium supplemented with various concentrations of coconut milk, coconut milk plus 2,4-dichlorophenoxy-acetic acid, kinetin, kinetin plus coconut milk, kinetin plus indoleacetic acid and indoleacetic acid alone The cultures were grown under fluorescent light ('Natural') giving 3,500 lux at the level of the cultures for 17 hr in 24-hr cycle The temperature was regulated at 24–26° C Some cultures with or without kinetin (0 1 mgm /l) were kept at the same temperature under low intensity of fluorescent light (700 lux) and blue light (400–570μ wave-length) giving 292 4 ergs/cm ^{2}/sec and 620 ergs/cm ^{2}/sec respectively at the level of the cultures for the same light hours Some of the results obtained are summarized in Table 1

It will be seen from Table 1 that coconut milk when supplied at 15 per cent concentration to the basal medium resulted in complete inhibition of bud formation in *Pohlia nutans* and in the decrease of radial growth of the protonema, but when supplied at

* Mean measurements of three similar agar cultures grown for 27 days

† Mean of three similar agar cultures of 27 days old

‡ Mean measurements of 20 cells from 20 different prostrate protonemal filaments taken at random from 47 days old agar cultures, figures in the following sequence minimum—mean—maximum

1 per cent concentration produced lesser number of buds than the control The inhibitory effect of coconut milk was overcome by the inclusion of 1 or 2 mgm /l kinetin into the basal medium containing 15 per cent coconut milk Table 1 also shows that almost similar effects were observed in cultures containing 10 mgm /l indoleacetic acid with or without kinetin Measurements of cell-size of protonemal filaments growing in different cultures containing the growth substances revealed that cells of maximum size were produced in a basal medium supplemented with 15 per cent coconut milk and of minimum size in a basal medium supplied with 10 mgm /l indoleacetic acid Addition of kinetin at 1 mgm /l concentration to the medium containing 15 per cent coconut milk resulted in the decrease of cell-width but produced a synergistic effect on cell-length of protonemal filaments, whereas the addition of the same to the medium containing 10 mgm /l indoleacetic acid could not affect cell-width but could increase cell-length

Experiments on the effects of low intensity of fluorescent light and blue light showed that buds were formed in cultures containing kinetin but not in the control

The findings with coconut milk are of interest in that not only the cell-size and cell-division are affected but also the organized development of the protonema remains least disturbed Coconut milk even in combination with 6 mgm /l 2,4-dichlorophenoxyacetic acid failed to produce abnormal protonemal growth, and in cultures containing 6 mgm /l 2,4-dichlorophenoxyacetic acid alone *Pohlia nutans* not only grew but also was characterized by bud formation Lal[3] observed the formation of callus-like protonema in *Physcomitrium coorgense* growing in a basal medium supplemented with 10 per cent coconut milk That 15 per cent coconut milk induces cell-enlargement but limits rate of cell-division to a certain extent will be seen when we correlate the extent of radial growth of the protonema with the cell-size of protonemal filaments of each treatment Otherwise we can expect the greatest radial growth in cultures containing 15 per cent coconut milk Furthermore, in the presence of kinetin, coconut milk and indoleacetic acid affected cell-width and cell-length of protonemal filaments in different manners

It may be inferred from the results reported here that the formative effect of kinetin on bud formation in *Pohlia nutans* has been further emphasized in the presence of low intensity of white light, of blue light and of coconut milk, which are found to interfere with bud formation The effects of 'active' and 'neutral'[4] fractions isolated from coconut milk and their effects in combination with kinetin may further illustrate the action of coconut milk on the development of the protonema and the initiation of shoot-buds in *Pohlia nutans*

Biosynthetic Pathways in Nutritionally Deficient Mutants of *Marchantia polymorpha* L.

Nutritionally deficient mutants of micro-organisms have provided valuable tools for investigating biosynthetic pathways Relatively few examples of such mutants are known in 'higher' plants[1,2] Methods have been devised to obtain nutritionally deficient mutants of a liverwort species, *Marchantia polymorpha*

Gemmæ are irradiated with X-rays and grown on a solid (agar) defined medium[3] at 17°–22° C A thallus arises presumably from a single apical cell at each of the two notches, at opposite ends of a gemma Thalli are observed at the end of the second week and scored either as normal (35 units long, measured by means of an ocular micrometer and a dissecting microscope) or as impaired (15 units or less) The latter thalli are excised and transferred to solid medium supplemented with 0 3 per cent yeast extract After three weeks on this medium, each thallus is diced, and fragments are added to defined yeast extract-medium to determine differences in growth This process is repeated twice Presumptive, nutritionally deficient mutants are then tested for growth on defined medium supplemented with vitamins, growth factors, purine, pyrimidines, or amino-acids, using techniques used for micro-organisms[4]

A population of 1,588 gemmæ was given 15,000 r X-rays A sample of 279 impaired thalli were screened to find nutritionally deficient mutants Of the 12 mutants which were found, 4 required either arginine or methionine or both Two mutants required arginine and one, methionine, a fourth mutant required either arginine or methionine Two arginine-deficient mutants were also able to use citrulline or ornithine and the third mutant, only citrulline Of the two methionine-requiring mutants, one was able and the other unable to use cysteine The poor growth of the latter mutant was noted visually The fresh and dry weights of the 4 mutants on defined medium and on defined medium containing specific supplements are summarized in Table 1 These results suggest that the ornithine cycle as well as the biosynthetic pathway

Table 1 GROWTH OF FRAGMENTS OF NUTRITIONALLY DEFICIENT MUTANTS OF *Marchantia polymorpha* REQUIRING EITHER ARGININE OR METHIONINE OR BOTH ON DEFINED MEDIUM WITH OR WITHOUT PRECURSORS OF THESE AMINO-ACIDS

Mutant No	Supplement	Fresh weight (mgm)			Dry weight (mgm)		
		Defined medium	+Supplement	Difference	Defined medium	+Supplement	Difference
44	arginine	71 05	167 69	96 64	1 84	4 95	3 11

Reduction of Plant Transpiration by Cetyl Alcohol

SURFACE monomolecular films of cetyl alcohol ($CH_3(CH_2)_{14}CH_2OH$) have been shown to reduce losses by evaporation from open water surfaces[1], and this application has had some successful use in Australia[2] There recently appeared a report[3] that the mixing of cetyl alcohol with the soil in which corn (*Zea mays*) plants were growing reduced their loss of water by transpiration by 40 per cent without reducing yield If it was confirmed that some substance could be taken up by plants which reduced their water needs without impairing growth, such a finding would have great potential agricultural importance. It was therefore decided to repeat Roberts's experiment on a pot scale, measuring the effects of cetyl alcohol on growth, transpiration rate and photosynthetic capacity

Wheat seedlings (var Sherpa) were raised under growth room conditions in pots containing 75 g of 'Vermiculite' Cetyl alcohol (obtained from British Drug Houses) was supplied at two levels, namely, 1 and 5 per cent of the dry weight for 'Vermiculite' in each pot There were twelve plants for each treatment plus eight controls Over the 20-day growing period pots were watered on two occasions with 100 ml of half-strength Hoagland solution, and daily with tap water The growth room was illuminated from a combination of warm white fluorescent tubes and incandescent strip lamps, and gave a light intensity of 1,200 ft candles at the base of the plants The carbon dioxide concentration was 400 p p m , air temperature 21° C Transpiration was measured gravimetrically in an air stream of a velocity of 7 ft /sec in the growth room The relative humidity was 80 per cent Net photosynthesis was determined at a carbon dioxide concentration of 300 p p m by measuring, with an infra-red gas analyser, the carbon dioxide consumed by the plant from a recirculating gas stream Light intensity was saturating (13 6 × 10^4 ergs/sec/cm^2 from high-pressure mercury-vapour lamps), leaf temperature was 25° C. After determination of leaf area, all plant material was dried for three days at 80° C in an oven with forced draught

The addition of 1 and 5 per cent cetyl alcohol induced foliar chlorosis and significantly reduced (P = 0 05 and P = 0 01) the growth of the wheat plants (Fig 1) However, the transpiration-rate on a leaf area basis was also reduced, there being a significant reduction (P = 0 01) with an application of 5 per cent cetyl alcohol, but the depression with 1 per cent was not significant (P = 0 05) (This effect has been reproduced in a second experiment) The rate of carbon dioxide fixation, on a leaf-area basis, was significantly reduced (P = 0 01) by both rates of

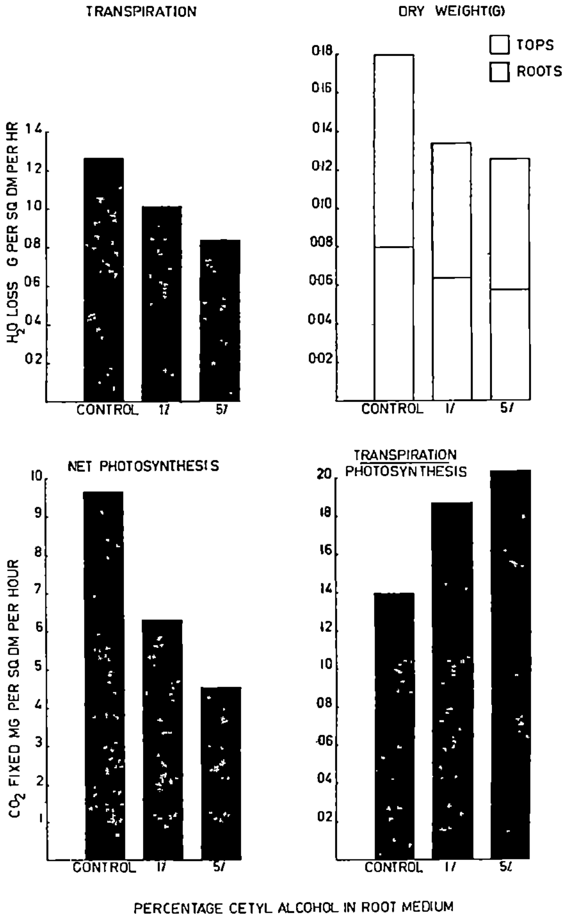

Fig 1

application of cetyl alcohol The resultant of these two effects on rates of transpiration and photosynthesis can be seen in the ratio of grams of water lost per milligrams of carbon dioxide This ratio increases with the application of cetyl alcohol

Thus, contrary to Roberts's[3] report, we find that cetyl alcohol when placed in the root medium of wheat significantly reduces growth, probably via reduction in photosynthetic rate However, it is also apparent that the rate of transpiration, on a leaf-area basis, is reduced The mechanism of this reduction in rate of foliar water vapour exchange is uncertain, however, it is possible that it is due to the translocation of cetyl alcohol into the vicinity of the spongy mesophyll of the leaf This is suggested, but not proved, by Roberts's observation of the movement of radioactivity into the leaves of plants to the roots of which cetyl alcohol labelled with carbon-14 has been applied

We thank Prof J S Turner, at whose suggestion this project was started, and also the Wheat Industry Research Council of Australia for support

Lack of Effect of Plasma Erythropoietin on Formate Incorporation into Nucleic Acids *in vitro*

RECENTLY, Perretta and Thomson[1] published a report on the marked stimulatory action exerted by a preparation of erythropoietin on the incorporation of formate labelled with carbon-14 into the bases of spleen and liver-slice nucleic acids This same preparation, they reported, had no such action on marrow suspensions incubated under the same conditions Since this finding appeared to offer a useful approach to the biochemical examination of the mechanism of action of erythropoietin and might also furnish a rapid sensitive *in vitro* assay for the hormone we undertook a confirmatory investigation Instead of the extract of alcohol-precipitated urine from anæmic rabbits we used a partially purified sheep plasma fraction, with the results summarized here These results do not confirm the findings of Perretta and Thomson

Experimental details were essentially as reported by Perretta and Thomson with the following exceptions as a source of erythropoietin, we used what we have termed the step III fraction[2], which had an activity of about 3 units per mg, the concentration used being 15 units/ml , and the incubation time 130 min The isolation and determination of specific activities of the purines and thymine were as described by Smellie *et al*[3] with some slight modifications All samples were run in duplicate and the averages are reported

It is clear from the results in Table 1 that we observed no marked stimulation of formate incorporation by any of the tissues In the case of spleen and marrow RNA and DNA, in fact, there was some depression of incorporation as a result of incubation with the erythropoietin-containing material

Among the differences between the experiments reported previously and those here, the most important may be differences in the amounts of erythropoietin used and in the non-erythropoietic contaminants in the two preparations Although we do not know how much erythropoietin activity was used by Perretta and Thomson, our own experience in another experiment in which 5 and 10 units per ml were used, rather than 15 units per ml as in the experiment reported in Table 1 suggests no consistent dose effect

0 15 ml packed marrow cells, 270 mg of slices of liver or spleen per sample , formate concentration, 9 6 μmoles/ml (4 85 μc/ml), incubation time 130 min

A, no added erythropoietin *B*, 15 units/ml erythropoietin

We feel that the clue to the discrepancies we have seen may lie in the nature of the contaminants present in the preparations The results reported by Perretta and Thomson show an appreciable depression of bone marrow formate incorporation caused by the control preparation from normal urine This same extract caused no stimulation when incubated with spleen or liver slices When the 'anæmic urine extract' was used the incorporation of formate of the marrow suspension was at about the normal level while there were large increases in the specific activities of the purines and thymine of spleen and liver These results suggest that the 'anæmic urine extract' contained a substance which stimulated formate incorporation in all three tissues, that the marrow was sensitive to an inhibitory material present in both urine extracts, and that the 'anæmic urine extract' was able to overcome the inhibitor action If these inferences are correct, then the difference Perretta and Thomson observed between spleen and liver on one hand and marrow on the other was quantitative, and the stimulation observed was not the result of erythropoietin action

ENTOMOLOGY

Neural Transplants and Insect Diapause

THE induction and maintenance of larval and pupal diapause are at present thought to be under the direct control of the neuro-endocrine complex associated with the insect brain Williams[1] found that diapausing pupæ of the cecropia moth, *Hyalophora cecropia*, could be induced to resume development by either a prolonged (6–12 weeks) exposure to a low temperature (4–6° C) or by the implantation of the brain of a previously chilled pupa Unchilled diapause pupal brains were found to be incompetent to induce development when implanted into an unchilled pupa in diapause The competence or incompetence of a pupal brain appeared to depend on the activity or inactivity of its neurosecretory cells When active, the neurosecretory cells are responsible for the production of a hormone that is released via the corpora cardiaca and activates the prothoracic glands, which then produce the growth hormone, ecdysone, responsible for the initiation of development[2] In the diapause pupa, the neurosecretory activity of the brain is suppressed[3], as is its neural impulse activity[4]

Highnam[5] reported that the neurosecretory cells of a sphingid moth contained no secretory granules early in the pupal diapause period During three weeks of exposure to low temperature, the cells began to secrete granules that passed down the axons into the corpora cardiaca After three weeks of such secretory activity, the pupal brain was competent to induce development when implanted into an unchilled pupa in diapause Secretory granules have been detected in the neurosecretory cells throughout the period of diapause in several species[6,7] It has not been demonstrated, however, that the presence of such granules indicates concurrent secretory activity, rather than storage of the products of previous elaboration[8]

The present investigation was undertaken in an effort to elucidate some of the humoral factors operative in the initiation, maintenance, and termination of the photoperiodically induced larval diapause of the European corn borer, *Ostrinia nubilalis* The methods used were similar to those previously reported in regard to culture medium, rearing conditions, and diapause induction[9] Surgical procedures were carried out aseptically, and tissue implantations were made into the middle abdominal segments of mature borer larvæ

Table 1 EFFECTS OF TISSUE TRANSPLANTS ON THE TERMINATION OF DIAPAUSE IN THE EUROPEAN CORN BORER

* D, Diapause
† ND, Non-diapause.

The role of the neuro-endocrine complex in the initiation and maintenance of larval diapause was investigated by means of a series of tissue transplants (Table 1) The implantation of the brains of diapause larvæ into mature non-diapause larvæ did not induce diapause or delay pupation Implantation of brain and neuroendocrine tissues of non-diapause larvæ into diapause larvæ resulted in the initiation of pupal and adult development Implants of sub-œsophageal ganglia, prothoracic ganglia, fat body, or testes did not cause diapause to be terminated These results are fully consistent with the concept that diapause is an arrested state that is enforced by the absence (or low titre) of the brain hormone required for the initiation of morphogenesis

Cytological examination of the corpora allata, corpora cardiaca, and neurosecretory cells of diapause and non-diapause larvæ failed to disclose any diapause-associated differences in granule inclusions, staining reactions, and cell size Although admittedly inconclusive, the neurosecretory cells of diapause larvæ did not look incompetent from the standpoint of their cytological state This finding led us to consider the hypothesis that the neurosecretory cells of diapause larvæ were competent from a synthetic standpoint, but that the elaborated products were not being released into the circulatory system This suggested that a physical or physiological brain barrier might be involved in the maintenance of the diapause state

The 'brain barrier' hypothesis was tested by transplanting tissues from diapause larvæ into other diapause larvæ of the same age and previous treatment (Table 1) Diapause brains implanted into diapause larvæ caused termination of diapause and pupation after about two weeks That the effect was caused by the parts of the brain containing the medial and lateral neurosecretory cells was demonstrated by the failure of other implanted structures to evoke development We have implanted brains of diapause larvæ 12–60 days old, and have found them all quite competent to induce development However incompetent the diapause brain may be *in situ*, it becomes competent when extirpated and implanted into another diapause larva

Although it has not been put on a quantitative basis, we have observed a distinct tendency for the number of days elapsing between brain implantation and pupation to be inversely proportional to the amount of tissue damage inflicted on the implanted brain during the surgical procedure The results of these experiments are interpreted as indicating that diffusible substances are released from the implanted brain following surgical destruction of the barrier between the neurosecretory cells and the circulatory system

Other interpretations of the experimental results are possible One is that the diapause brain normally elaborates and liberates neurohormones at a rate too low to induce development, the implanted brain simply raises the hormone titre above the developmental threshold This possibility has been eliminated by experiments in which the host brain was removed by ligation and a diapause brain implanted into the abdominal cavity Larvæ so treated contained but one brain, but diapause was terminated, the larvæ pupated The hormonal output of the implanted brain was apparently sufficient to induce pupation Another possible interpretation of these results is that injury metabolism in the implanted brain tissue was sufficient to elevate the rate of neurosecretion and induce development This seems unlikely because such a non-specific effect has not been found in other species Williams[1] reported that as many as eight incompetent diapause brains implanted into a single diapausing pupa of cecropia failed to induce a resumption of development

It seems likely that the 'brain barrier' is an absence of impulse transmission in the neurosecretory axons, as there is some evidence supporting the idea that impulse transmission is necessary for the intraaxonal translocation of neurosecretions[10] Tissue injury during surgery may result in (1) a resumption of neural activity, (2) mechanical release of secretory products, or (3) facilitate the diffusion of blood-borne substances into the implanted brain tissue. In any case, the barrier between neurosecretion and the circulatory system is eliminated, and the neurosecretory products are able to exert their physiological action of evoking metamorphosis.

Publication of this communication has been approved by the Director of the Wisconsin Agricultural Experiment Station.

Effect of 'Rogor' (Dimethoate) and DDT on Cotton Mites in Uganda

THREE species of mites are known to attack cotton in Uganda. These are yellow tea mite, *Hemitarsonemus latus* (Banks)[1], red mite, *Tetranychus telarius* (L.)[2], and 'green mite', *Eotetranychus* sp. nr. *deflexus* (McGregor).

Tea mite is widespread and common, and though it can cause considerable leaf damage it has not been shown to reduce yields in Uganda[3], it is readily controlled by DDT-miscible liquid sprays[3]. The cotton red mite is of doubtful taxonomic status[2,4,5], and it would seem advisable to leave it as 'the *T. telarius* complex'. It is widespread and common on cotton, particularly at senescence, though excessive applications of DDT can cause severe attacks and complete defoliation[6]. *Eotetranychus* sp. is a new record for cotton in Uganda. It was first discovered at Kawanda Research Station early in 1961 and afterwards at widely scattered sites over the whole country. It may be a potential new pest or it may be that an exceptionally wet growing season provided a suitable breeding environment.

In view of the possibility of an increase in green mite and the fact that it can occur on the same plant as red mite it was decided to work out a joint control. Coaker[6] showed that 0·05 per cent parathion and 0·025 per cent 'Aramite' gave good control of the *T. telarius* complex in Uganda and McKinlay[7] that both 'Rogor' and 'Metasystox' at 0·0125 per cent gave good control in Tanganyika. Field application of 0·0125 per cent 'Rogor' at ten-day intervals does not give satisfactory control in Uganda but 0·06 per cent does (unpublished work).

Cotton leaves infested with both red and green mite were maintained in the laboratory with their petioles dipped in water. Active stages of both tetranychids were dead or dying within 4 h of spraying with 0·1, 0·05 or 0·025 per cent 'Rogor', while tea mites, which were also present on the leaves, remained perfectly healthy. Larvæ of both red and green mite hatching after 24 h were killed, but those after 48 h lived and fully re-established the colony after a week.

A further trial was laid down using leaves infested with all three species of mites in which 1 per cent DDT-miscible liquid, 0·02 per cent 'Rogor'-emulsifiable concentrate and a mixture of both 1 per cent DDT and 0·02 per cent 'Rogor' were sprayed on to either the upper side or the lower side of the leaves only. The 1 per cent DDT m.l. applied to the lower sides of the cotton leaves killed the active and the quiescent stages of all three species of mites, tea mite disappeared completely within 4 h while the tetranychids remained twitching on their webs for days before finally dying. Healthy larvæ of all three species re-appeared within 4 days and the colonies were re-established within 8 days. The same spray applied to only the upper surface of the leaves gradually reduced the numbers of actively wandering tea mites but had no effect on either red or green mite. The 0·02 per cent 'Rogor' applied to either surface had no effect on tea mite. Applied to the lower leaf surface it killed both red and green mite within 4 h and hatching larvæ died over the following 2 days but after 4 days there were no visible toxic effects. 'Rogor' sprayed on to the upper surface only had no effect on red or green mite living on the underside of the leaf and so cannot be absorbed by the cotton leaf under these conditions. With the mixture of DDT and 'Rogor', all three species were dead within 2 h, and no living larvæ were seen until the fourth day and re-establishment of the colonies was delayed until the twelfth day. The same mixture applied to the upper leaf surface gradually reduced the tea mite numbers, but the tetranychids increased. On the control leaves both the red and green mite numbers increased continuously but the tea mite population gradually decreased, as they either died naturally or wandered off the leaves. It was interesting to note that a large, active, predatory mite, as yet unidentified, was unaffected by either insecticide.

After observing the failure of 'Rogor', a known systemic insecticide, to kill red or green mite living on the underside of the leaves when applied to the upper, another trial was laid down in which unsprayed leaves had their petioles dipped into 'Rogor' instead of water. 0·1 and 0·05 per cent 'Rogor' were used and within 24 h both red and green mite were dead but tea mite was still alive. 'Rogor' absorbed into the leaves in this way proved to be highly phytotoxic and within three days all the treated leaves were dead or dying.

It is concluded that 0·02 per cent 'Rogor' as an underleaf spray is an effective contact poison against red mites of the *T. telarius* complex and green mite, *Eotetranychus* sp. nr. *deflexus*, but that it does not appear to be absorbed by the cotton leaf when sprayed on to the surface. 'Rogor', even as strong as 0·1 per cent, has no effect on tea mite, *H. latus*. A good wetting spray of 1 per cent DDT is a slow-killing poison to both red and green mite and is extremely lethal to tea mite. The residual toxicity appears to be no more than 4 days for either insecticide under the conditions of the experiment. There is no evidence of either toxicant having any action on the eggs of any of the three mite species. A good field control should be obtained with a mixture of 1 per cent DDT m.l. and 0·02 per cent 'Rogor' e.l. applied as an 'up and under' spray, but from the laboratory evidence a second application would be required about 12 days later.

I thank the Commonwealth Institute of Entomology for its help in identifying the *Eotetranychus* species.

Anæsthesia and the Action of DDT on *Anopheles* Larvæ

DR. J. C. JONES[1] has reported that "anæsthesia . . . interferes in some important way with the obtainment of a lethal dose of DDT" by larvæ of *Anopheles quadrimaculatus* Say. If this effect were involved with the metabolic processes of the insect, one might make a case for the intriguing concept of 'active' uptake of this poison. If, however, the effect is simply one of producing a lower exposure to the insecticide by decreasing the physical activity of the larvæ, it is, obviously, worth no further investigation. On the basis of the following evidence: ". . . anæsthetized larvæ which are drawn about within the [DDT] suspension by cardboard tips are entirely comparable to those left completely quiescent", Jones ruled out the latter possibility.

Since the hypothesis of 'active' uptake is an attractive one, and has generally been neglected, we have endeavoured to expand Jones's work. It can, indeed, be shown that fourth-stage larvæ of *A. quadrimaculatus* are protected from the insecticidal effects of DDT by the action of any of several anæsthetics (Table 1). Further experimentation, however, occasions our assertion that this effect is, in spite of Jones's views to the contrary, a physical one.

Table 1. EFFECTS OF ANÆSTHETICS ON INSECTICIDAL ACTIVITY OF DDT

		Alive	Dead
		at 24 h*	
(1)	Ether–DDT	15	5
	DDT	0	20
	Ether–water	18	2
(2)	CO_2–DDT	15	5
	DDT	7	13
	CO_2–water	18	2

(1) 20 larvæ immersed in 3·5 per cent ether in water for 10 min, washed twice for 2 min with water, exposed to DDT (4 mg of *p,p*-DDT dissolved in 4 ml. of acetone and suspended in 100 ml. water) for 10 min, washed twice for 2 min with water, and placed into individual shallow water-filled containers for 24 h at 80° F.

(2) 20 larvæ exposed to carbon dioxide-saturated water for 10 min then placed in carbon dioxide-saturated DDT (made up as above) for 10 min, washed twice for 2 min with water, and incubated as above.

* Each result is an average of two replicates of 20 individuals.

Four groups of twenty larvæ were anæsthetized with carbon dioxide by bubbling the gas for 10 min through water in which they were immersed. Each group was then transferred to a separate container of DDT of sufficient strength to kill within 24 h 75–100 per cent of the animals exposed to it for 10 min. Group 1 was permitted to remain completely motionless for the 10-min interval; carbon dioxide was bubbled for 3 min through the DDT suspension in which group 2 had been placed, after which these larvæ were left undisturbed for the remaining 7 min (although completely anæsthetized, they were in motion in DDT for 3 of the 10 min); group 3 was kept in motion by the bubbles of carbon dioxide for 7 min, then left immobile for 3 min; group 4 was disturbed for the whole period. The experiment was completely carried out in an atmosphere of carbon dioxide, so there was no possibility of any larva becoming active during the time it was undisturbed by the bubbling gas. Table 2 clearly shows that larvæ which are kept in flux are unprotected by carbon dioxide even though metabolically torpid. To substantiate this, an experiment was done in which larvæ were anæsthetized with ether and subsequently stirred vigorously in a DDT solution while still in a flaccid state. The results obtained with this anæsthetic were the same as those reported above.

Table 2. EFFECTS OF MOVEMENT OF ANÆSTHETIZED LARVÆ ON ACTIVITY OF DDT

				Alive	Dead
				at 24 h*	
(1)	CO_2–DDT	quiescent	10 min	13	7
(2)		in motion	3 min	6	13
(3)		in motion	7 min	3	17
(4)		in motion	10 min	2	18
(5)	DDT			0	20

(1)–(4). Four groups of 20 larvæ exposed to carbon dioxide, as in Table 1, section 2.

* Each result is an average of two replicates of 20 individuals.

Whether the protective effect of anæsthesia is attributable to the very low rate of diffusion of DDT, limiting the amount of contact with the immobile larval surface in the time period involved, or to the decreased larval surface exposed as a result of cessation of movement, is not known at this time. In accord with the overall findings, however, is the work of Lewis[2], who has shown that Risella oil spreads quite rapidly over the cuticle of blowflies only when they are moving, and assigns this effect to elastic submicroscopic movements in the cuticular surface associated with walking.

MICROBIOLOGY

Origin of the Endoplasmic Reticulum

To propose a mechanism of origin of the endoplasmic reticulum based on a study of yeast cytology may seem presumptuous because there is no field in which so many different opinions prevail. The variety of opinions have arisen because yeasts, like all acellular (single-celled) organisms, manifest a maximal diversity of internal organization, and a limited number of these manifestations are considered by different individuals to be typical, and because yeast cytology has engaged the interest of those who are primarily interested in yeast and only secondarily interested in cytology. But the fact that almost the entire internal organization of a small (5μ) structure may be revealed by as few as 20 serial sections, while thousands of comparable sections (each much larger) would be required to trace the internal organization of the more familiar liver cell, makes the smaller yeast cell a more useful object in respect to tracing the relationship of the reticulum to the nucleus.

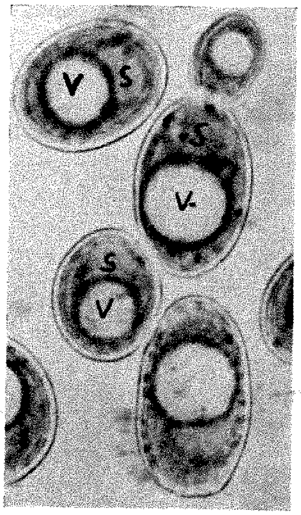

Fig. 1. Ultra-violet photomicrograph of yeast cells which were removed from a rapidly growing culture and starved overnight in phosphate buffer. The synthesis of nucleic acid is greatly diminished. The ultra-violet absorbing nucleic acid (soluble transfer of RNA) is streaming into the cytoplasm from the nuclear vacuole (*V*) and not from the spindle (*S*)

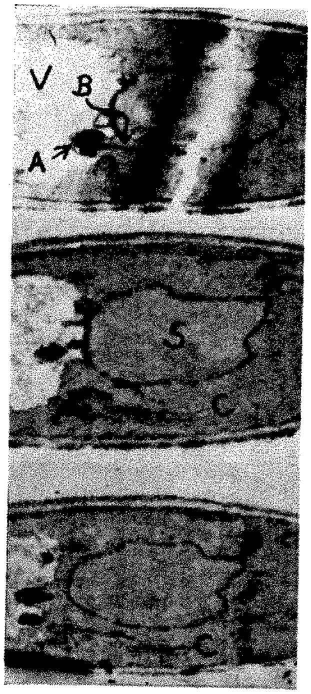

Fig. 2. Three serial sections of a single yeast cell showing the endoplasmic reticulum (*C*) folded in the cytoplasm. The vestibule (*A*) of the assembler has been retracted into the vacuole by fixation. The assembler is the Feulgen-positive structure which is revealed by light microscopy as a crescent closely applied to the surface of the spindle reservoir (*S*) (ref. 9). The vestibule and the extruder duct (*B*) are electron-dense when stained with uranyl acetate, which is specific for nucleic acid

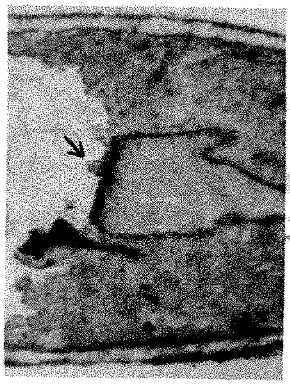

Fig. 3. A section of the yeast cell shown in Fig. 2 revealing the vestibule and the extruder duct, and also the vent (at arrow) leading from the spindle reservoir into the nuclear vacuole

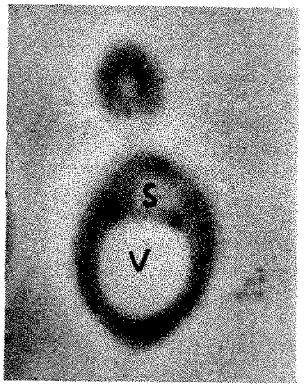

Fig. 4. A phase-contrast (visible-light) photomicrograph showing the assemblers in a living yeast cell

Caspersson's original proposal[1] that all nucleic acid originates from the nucleus has been abundantly confirmed, and ultra-violet photographs of living yeast cells from his laboratory[2] and from ours[3] have been interpreted by me as indicating that soluble (amino-acid carrier) nucleic acid passes directly through the wall of the nuclear vacuole into the cytoplasm (Fig. 1). Analysis of electron micrographs of serial sections of yeast cells, made by Dr. Tadashi Hirano, suggest that the endoplasmic reticulum[4] (and the attached ribosomes[5]) also arise from the nuclear vacuole, passing into the cytoplasm through a specialized organelle, the assembler (Fig. 2) comprising: (1) a funnel-shaped vestibule (*A*) leading from the nuclear vacuole (*V*) into (2) an extruder duct (*B*), through which the endoplasmic reticulum (with its ribosomes) passes into the cytoplasm. While the soluble nucleic acid (transfer RNA) is streaming directly through the membrane of the nuclear vacuole into the cytoplasm, the Feulgen-positive chromosomes and the ribonucleic acid and other components, destined to become ribosomes and endoplasmic reticulum, are packed into the vestibule of the assembler. The presence of the chromosomes in the assembler suggests on one theory of gene action[6] that the messenger RNA is transferred from the gene locus to the ribosome in the assembler. On this concept, the endoplasmic reticulum (*C*) (carrying the ribosomes coated with messenger RNA) issues from the extruder duct in the form of a long ribbon which folds as it emerges into the cytoplasm. The most distal extension of the ribbon carries the oldest ribosomes, and the most proximal region, near the exit of the extruder duct, carries the most recently synthesized ribosomes. A vent from the spindle reservoir (*S*) leads into the nuclear vacuole to permit the passage of the chromosomes from the spindle reservoir into the vacuole (at arrow in Fig. 3).

There are two assemblers attached to each nuclear vacuole, thus explaining the long-standing misconception, originating with Badian[7,8], that the yeast cell contains two Feulgen-positive chromosomes. Fig. 4 is a phase-contrast (visible light) photograph showing both assemblers occupying their characteristic positions in the living cell. The turgid vacuole and the fainter but equally turgid spindle are characteristic of the rapidly growing yeast cell and suggest that hydrostatic pressure pushes the chromosomes into the vestibule and provides the current which moves the soluble nucleic acid through the membrane.

Occurrence of Sialic Acid in some Gram-positive and Gram-negative Pathogenic Bacteria

Aaronson and Lessie[1] searched for sialic acid in ten species of bacteria and detected it only among the Gram-negative organisms. In continuation of our findings with *Pasteurella pestis*[2], we have screened many pathogenic bacteria for the presence of sialic acid.

The micro-organisms were grown in the conventional liquid media or nutrient agar as indicated. After testing for the purity of the cultures, they were washed out with saline in the case of agar growths and the bacterial mass collected by centrifugation. After washing once with water, the cells were triturated with cold acetone (– 20° C.) and acetone powders prepared as usual. Fractionation of these were made as reported earlier[2] and the sialic acid estimated by the thiobarbituric method[3] after extraction of the chromogen with isoamyl alcohol to remove the colour produced by deoxyribose. We did not meet with the difficulties referred to by Forbes and Ruck[4]. The results obtained are given in Table 1. There is some destruction of sialic acid in the acid treatment and on hydrolysis.

In its sialic acid content also *Past. pseudotuberculosis* resembles closely *Past. pestis*. The *Salmonella* organisms, *Bord. pertussis* and *Ps. pyocyaneus*, contain sialic acid. The case of *V. cholerae* is of interest in that the sialic acid content is negligible or very low in the four strains studied. It is of interest to find out whether the presence of the receptor-destroying enzyme in this organism, which is a sialidase[5], has anything to do with the low sialic acid content. Among the Gram-positive bacteria studied, sialic acid was not detected in *C. diphtheriae*, and there seems to be a trace in *Staph. aureus*. The definite presence of sialic acid in the Gram-positive *Strep. faecalis* does not confirm the belief[1] that sialic acid is present only in Gram-negative organisms.

We thank Dr. M. K. Habbu, Mr. R. S. Karbhari, and Mr. A. S. Narasimhan for help in growing the cultures and checking the purities. We also thank the Haffkine Institute Diamond Jubilee Research Committee for the award of a senior fellowship to one of us (R. J. I.).

Spermicidal Activity of Bacterial Endotoxin

THE endotoxins of Gram-negative bacteria are a group of macromolecular lipopolysaccharide complexes which, on administration to experimental animals, produce a wide variety of physiological and pathological alterations[1,2]. Despite the similarity of some of the pathological findings in these varied reactions neither a common factor nor a basic mechanism responsible for the pathogenesis of these reactions has been established, and there is evidence that significant underlying physiological differences exist in some of these phenomena.

Endotoxins have been isolated from a wide range of Gram-negative bacteria. Little attention has been given to micro-organisms from the genital tract although Gram-negative organisms comprise a large part of the pathogens involving this system in man and animals. Brucellosis of cattle, sheep and swine, and vibriosis of cattle, for example, are at present responsible for heavy annual losses in the livestock industries. Recently, a toxic lipopolysaccharide has been isolated from *Vibrio fetus* by the phenol–water extraction method[3] and has been shown to possess many of the chemical and biological properties of the classical Gram-negative bacterial endotoxin[4]. In the course of examination of the pathogenesis of *V. fetus* infection this lipopolysaccharide has been found to be spermicidal *in vitro* to both ram and bull spermatozoa.

In these experiments the semen of rams was collected by electro-ejaculation[5], and only apparently normal specimens with good initial motility were used. The semen was diluted 1 : 20 in calcium-free Ringer's phosphate solution in small tubes for motility observations which were made at 37° C. The lipopolysaccharide solution was dialysed against distilled water at 2°–4° C. for 14 days prior to use. All the tubes were checked for any alteration in *p*H. Motility was scored at hourly intervals by the system of Emmens[6].

The ram spermatozoa were immobilized at the end of the first hour at the concentration of 100 μgm./ml. and higher and only the tails were moving. All activity had usually ceased after 3 h (Fig. 1).

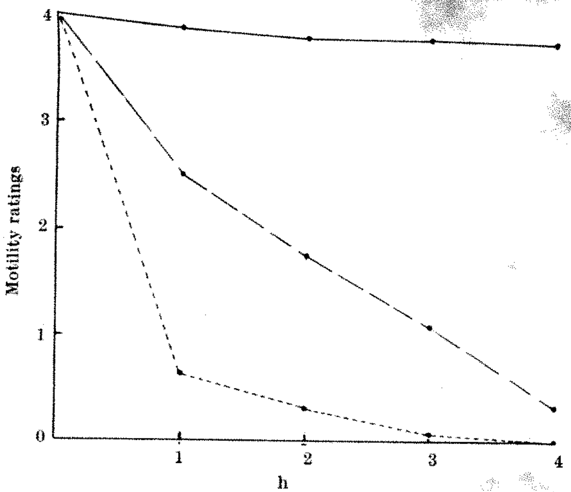

Fig. 1. Motility decreasing effect of lipopolysaccharide of *V. fetus* on ram spermatozoa *in vitro* at 37° C. – – –, 100 μgm. lipopolysaccharide; - - -, 1 mgm. lipopolysaccharide; ——, control

The mean effective dose was shown to be 227 μgm./ml. Preheating the lipopolysaccharide increased the activity up to five-fold, a finding in keeping with the other specific activities of Gram-negative bacterial endotoxins[7]. The control tubes showed little or no diminution in motility over the 4-h test period. Limited studies with bovine spermatozoa suggested that the lipopolysaccharide of *V. fetus* appeared to be more spermicidal in this species, by decreasing the motility in a shorter period of time and at a lower concentration. This suggestion is in keeping with the epidemiology of both bovine and ovine vibriosis.

The effect of lipopolysaccharide on the motility of spermatozoa is non-specific for *V. fetus* as the lipopolysaccharide of both *Pasteurella multocida* and *Serratia marcescens* were also shown to be effective, indicating that the spermicidal activity is, in general, another specific effect of Gram-negative bacterial endotoxins. The lipopolysaccharide of the non-pathogen, *Serr. marcescens*, was the most spermicidal of the three to the ram spermatozoa and the mean effective dose was calculated to be 78 μgm./ml.

Thomas[8] considers that the only known primary actions of endotoxin are those arising from injection into the sub-arachnoid space and the release of a pyrogen by the addition of endotoxin to leucocytes. With these two exceptions, Thomas[8] states that to his knowledge no other phenomena can be ascribed to the direct effects of endotoxin. In addition, he states that he does not believe that anyone has succeeded in showing a direct effect of endotoxin *in vitro*. It is proposed that the spermicidal activity of bacterial endotoxin is a specific type of endotoxin-induced pathological alteration having a direct effect upon a mammalian cell *in vitro* and exhibits certain significant differences from several of the other endotoxin-induced lesions.

I thank Mr. R. V. S. Bain and Dr. I. G. White for advice.

GENETICS

Twinning and Haploidy in *Cocos nucifera* Linn.

IN the coconut, *Cocos nucifera* Linn., the ovary is tricarpellary and each carpel contains an ovule. Usually only one ovule develops and two abort, and although there are three depressions or 'eyes' in the endocarp wall of the mature fruit only one of these is a functional germ pore. From this eye normally a single shoot emerges.

Exceptions to this pattern include the functioning of extra germ pores[1-3], and the production of additional shoots from one germ pore[4,5], a rare occurrence according to Menon and Pandalai[6].

Most observations have so far been on seedling and mature palms[7] and Harland[8] has discussed the value of polyembryony in physiological and breeding studies. Recently, however, Guevara[9] has described two twin embryos in both instances lying beneath a single germ pore. In one pair the embryos were completely separated and in the other were joined. The extra embryo in the first pair he considered to be most likely of synergid origin but it could have resulted from cleavage of one embryo.

In Jamaica, from a collection of 75 seed nuts each with more than one shoot, 71 were twins and four were triplets. When the husks of 33 of these nuts

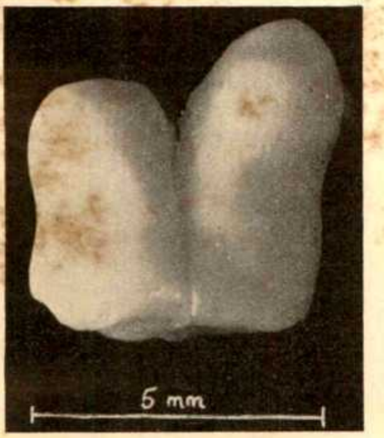

Fig. 1. A twin embryo of *Cocos nucifera* Linn. from a mature ungerminated nut

including two triplets were removed it was found in each case that all shoots emerged from one germ pore. Further, although members of a pair often differed in size there was generally no other marked morphological difference.

Studies of these 31 twin seedlings showed all states between complete fusion of the haustoria within the nut and complete separation, and the majority were apparently diploid–diploid.

These observations suggested that twins often arise as a result of cleavage in a single embryo, and the discovery of a partially cleaved embryo pair from an ungerminated nut shown in Fig. 1 tended to support this. That separation of this embryo pair was incomplete is shown in Fig. 2, where a small area (*C*) of cells common to both is evident.

In only one pair of twins so far examined have marked differences between partners been observed. The twins were found to be completely separated and further showed considerable disparity in vigour. The suspicion that the less-vigorous plant was haploid was confirmed when it was shown to have 16 rather than 32 chromosomes per cell. The diploid plant had a bronze rachis whereas that of the haploid was green and the latter had noticeably more slender leaves. Unlike the diploid the margins of the haploid rachis were fused together.

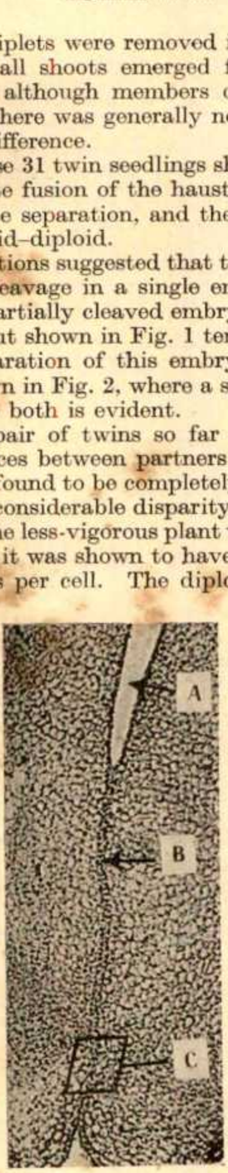

Fig. 2. Photomicrograph of a section of the region between the embryos in Fig. 1. In *A* complete separation has occurred; *B* shows the line of cleavage; *C* is an area of tissue common to both embryos

This is apparently the first record of haploidy in *Cocos nucifera* and in addition is an example of a second kind of twinning.

The value of haploids in coconut cytogenetics and breeding will naturally depend on their frequency and the ease with which they can be converted into diploids. At present it appears that haploid–diploid twins are much less frequent than diploid–diploid twins.

CYTOLOGY

Non-Random Distribution of Certain Homologous Pairs of Normal Human Chromosomes in Metaphase

Developments over recent years in the technique of cell culture and chromosome analysis have made available considerable numbers of photographs of mitoses. From these, information can be gained rather simply as to the distribution of chromosomes in metaphase, whether it is random, and more particularly whether certain chromosomes tend to lie close together.

Barton and David[1] and Stewart[2] have developed methods for studying this problem, the former finding a slight suggestion of homologous association of all chromosomes within a single cell, the latter finding random spread of all chromosomes within ten cells. Difficulty exists, however, in assigning most chromosomes to the correct pairs, and wrong assignment would tend to swamp any evidence of non-randomization.

We wish to report results obtained on several chromosome pairs which were chosen because they can be unequivocally identified. These showed significant evidence of non-random dispersion in metaphase and of homologous association.

Thirty photographs, measuring approximately 15 cm.^{2}, of cultured peripheral blood and skin cells of normal males and females were obtained from members of the Galton Laboratory. (We thank R. Chitham, J. Delhanty, J. Ellis, K. Lele, R. Marshall and U. Mittwoch for providing photographs and karyotype analyses.) Distances were measured between the centromeres of homologous members of pairs 1, 2, 3 and 16 (Denver System) and compared with distances between a randomly chosen member of each pair and three randomly chosen chromosomes. Thus, for example, the distance, $X(1,1')$ between homologous members of pair 1 was measured and compared with three distances, $X(1,\alpha)$, $X(1,\beta)$, $X(1,\gamma)$, between a member of the pair and three randomly chosen chromosomes, α, β, γ. The difference $\bar{d} = \frac{1}{3}[X(1,\alpha) + X(1,\beta) + X(1,\gamma)] - X(1,1')$ will tend to be positive on the average if there is association between homologous chromosomes; this was tested statistically by comparing the mean $\bar{d}$ over all 30 plates with its standard error σ, according to the usual *t* test (with 29 d.f.). This test does not use all the available information, but it has the convenience of being easy to compute.

Table 1

Pair	$\bar{d}$ (cm.)	*S.E.*, σ	$t = \bar{d}/\sigma$	*P* (two-tail significance-level)
1	0·63	0·42	1·50	0·15
2	0·30	0·45	0·67	0·48
3	1·20	0·47	2·55	0·017
16	0·82	0·36	2·28	0·03
Total	2·95	0·86	3·43	0·002

As can be seen, a tendency toward homologous association was present in all four pairs. In pairs 1 and 2, this effect did not reach levels of significance; in pairs 3 and 16, the effect was significant at the 5 per cent level. Pooling the data shows an overall tendency of homologous association with a high degree of significance.

As a control, the same measurements were made between randomly chosen members of each pair under examination and a randomly chosen non-homologous chromosome. Similarly, these distances were then compared with those between the chosen member of the pair under study and three other chromosomes chosen at random. Values for the mean $\bar{d}$ and its standard error σ were obtained as before. These results showed no significant deviation from the null hypothesis, and thus give further support to the significance of the above findings.

Table 2

Pair	$\bar{d}$ (cm.)	*S.E.*, σ	$t = \bar{d}/\sigma$	*P* (two-tail significance-level)
1	0·42	0·71	0·59	0·56
2	−0·31	0·90	−0·34	0·74
3	0·31	0·80	0·39	0·70
16	−0·10	0·89	−0·11	0·91
Total	0·32	1·7	0·85	0·40

On the suggestion of Prof. L. S. Penrose, a further test of the study method was made, utilizing the observation that certain acrocentric chromosomes, for example those of the 21–22 group, are known to exhibit terminal associations and would be expected to lie close to one another[3]. From twenty mitotic plates of male cells a mean of all six distances between the members of chromosome pairs 21 and 22 was obtained. This was compared with the mean distance between six randomly chosen pairs of chromosomes. The differences, $\bar{d}$, were subjected to *t* test analysis and the results confirming the presence of association within the group were consistent with cytological observations.

Table 3

Group	$\bar{d}$ (cm.)	*S.E.*, σ	$t = \bar{d}/\sigma$	*P* (two-tail significance-level)
21–22	1·4	0·68	2·08	0·054

This investigation offers evidence that homologous members of chromosome pairs 1, 2, 3 and 16, which were chosen because of their ease of identification, tend to lie closer together than would be expected by chance in metaphase plates. That pairs 1 and 2 did not show the tendency so significantly as pairs 3 and 16 might be due to real differences of behaviour during mitosis or might simply be a result of their greater size. All cells studied had been subjected to metaphase arrest with colchicine, a substance which disrupts spindle formation. It is possible, therefore, that more conclusive results might be obtained from cells in which colchicine is not used.

VIROLOGY

Control of Virus Yellows in Sugar Beet Crops

VIRUS yellows, transmitted by aphids, causes great damage to sugar beet crops in north-west Europe. In Britain its incidence at the end of August in the years 1946–61 is shown in Fig. 1.

This incidence has been converted into estimates of sugar beet tonnage lost[1]; in the exceptional year 1957 this amounted to 1,039,000 tons, and in the three years 1958–60 it averaged 427,000 tons.

As we now know that two separate viruses are responsible for virus yellows[2], and that mild yellowing virus, the more common one, causes only 50–60 per cent of the loss of yield produced by severe yellows[3], it would be prudent to reduce these estimates of loss by 25 per cent.

In the four years 1957–60 the addition of these tonnages, so reduced, would have increased farm incomes in Britain by an average of £2,610,000 per annum. Moreover, large-scale spraying with systemic insecticides commenced in 1957, and in the three years 1959–61 a mean of 309,000 acres out of the total of 411,000 acres of the sugar beet crop were sprayed one or more times with aphid-killing insecticide, at an average cost of more than £1,000,000 per annum. This new control measure had no beneficial effect on the overall incidence of the disease (mean August incidence, 1946–56 = 13·2 per cent; 1959–61 = 17·5 per cent; see Fig. 1).

There is much evidence[4–12] that overwintering sugar beet and mangold seed crops are the important

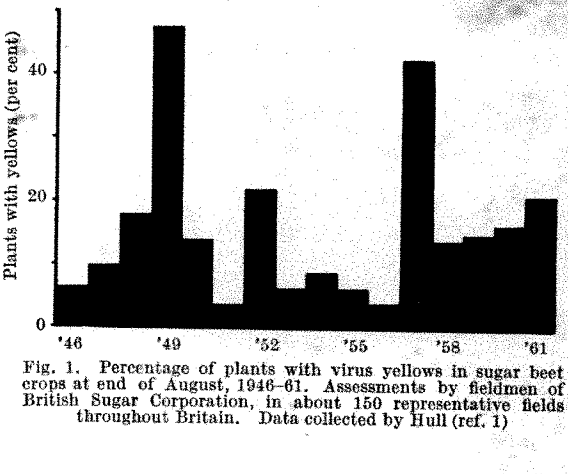

Fig. 1. Percentage of plants with virus yellows in sugar beet crops at end of August, 1946–61. Assessments by fieldmen of British Sugar Corporation, in about 150 representative fields throughout Britain. Data collected by Hull (ref. 1)

winter reservoirs of these viruses. Therefore the disease would be greatly reduced if the seed crop could be eliminated.

Beet seed is readily stored and keeps its germinating capacity for a long time; under ordinary warehouse conditions this capacity is only reduced by 50 per cent after storage for 5–9 years[13]. Moreover, beet and mangold seed crops occupy less than 3,000 acres of Britain. If seed crops of sugar beet and mangold were grown, throughout Britain, only in alternate years, the virus cycle would be broken and the disease controlled. Under the Destructive Insects and Pests Acts 1877 to 1927, the Minister of Agriculture possesses general powers to make Orders to prevent the introduction or spread of any disease or pest destructive to agricultural crops in England and Wales, and such Orders may include provisions to control and prohibit the growing of specified crops.

Sugar Beet Mild Yellowing Virus: a Persistent Aphid-transmitted Virus

I have shown[1-3] that there are two aphid-transmitted viruses which commonly cause yellowing of sugar beet leaves in eastern England. One of these is beet yellows virus (SBYV), first described by Roland[4], and the other has been called sugar beet mild yellowing virus (SBMYV) by me[1]. The two viruses are apparently unrelated.

The virus–vector relationships of SBYV and *Myzus persicae* (Sulz.) have been examined in detail by Watson[5,6] and later by Sylvester[7]. *M. persicae* acquired SBYV by feeding on infected sugar beet plants for 5–10 min., but the probability of successful transmission was increased by longer feeding times up to 12 hr.; the virus persisted in the aphid for less than 72 hr. in aphids feeding on virus-free plants and Sylvester consequently classified SBYV as a semi-persistent virus. Viruliferous aphids only needed to feed on healthy plants for a short time to cause infection, although the proportion of successful transmissions increased with longer test feeding times up to 6 hr. Watson[8] has reported that viruliferous aphids are no longer able to transmit SBYV after moulting.

The virus–vector relationships of SBMYV have now been studied at the Plant Breeding Institute, Cambridge, and the purpose of this communication is to report that this virus, unlike SBYV, is a true persistent virus. Very few successful transmissions were obtained when *M. persicae* was allowed to feed for 24 hr. or less on infected plants; the aphids appeared to reach maximum transmission efficiency after three or more days infection feeding. Test feeds of 24 hr. or more were necessary for efficient transmission, the best results being obtained by test feeds of 48 hr. or more. The results of one experiment in which the virus–vector relationships were studied are shown in Table 1. Other experiments have given similar results.

Table 1. Number of Successful Transmissions of SBMYV to Sugar Beet (20 Plants per Treatment) using Five *Myzus persicae* per Plant

Time on healthy plants (hr.)	Time on infected plants (hr.) 2	8	24	48	72	96	120	Total
2	0	0	0	4	9	10	11	34
8	0	0	3	7	10	11	8	39
24	0	0	6	10	16	15	19	66
48	0	0	6	14	20	19	20	79
72	0	0	5	17	20	20	20	82
Total	0	0	20	52	75	75	78	

SBMYV persisted for long periods in *M. persicae*; a large proportion of aphids which had fed for 4 days on infected sugar beet were still able to transmit the virus after 9 days on *Brassica pekinensis*, which is immune to SBMYV. It has also been shown that, unlike SBYV, aphids which have acquired SBMYV could still transmit the virus after moulting without access to further sources of virus.

In experiments to find better test plants than sugar beet for SBMYV in the glasshouse, *Claytonia perfoliata* Donn. and *Capsella bursa-pastoris* Medik. were found to be very suitable for this purpose. Bjorling[9] showed that *C. perfoliata* is susceptible to SBYV, the leaves of infected plants showing numerous red spots; however, in plants infected with SBMYV the distal halves of the older leaves became a deep pink colour but without red spots within 2–3 weeks after inoculation. SBMYV was recoverable from *C. perfoliata* without difficulty. The symptoms of SBMYV infection in *C. bursa-pastoris* were a yellowing or purpling and thickening of the older leaves, often associated with marked stunting.

SBMYV is a persistent virus and SBYV a semi-persistent virus; this difference might influence the pattern of spread of the two viruses in the field, which could explain the observed differences in their distribution in East Anglia[1-3].

A New Living Vaccine against Fowl Plague Disease

In a previous investigation[1] three attenuated substrains from a pea fowl strain were obtained by serial passages mainly in pigeon embryos. One of these substrains ($PFC_2\ P_{11}\ C_{30}$)—that is, pea fowl strain subjected to 2 passages in chick-embryos, 11 in pigeon-embryos and 30 in chick-embryos successively—was subjected for further attenuation to more than 400 passages in pigeon embryos using either the intra-allantoic or the intra-yolk route of inoculation. During these passages 33 desiccated batches were prepared from the pigeon embryos. These batches were titrated in chick-embryos, fowls, and afterwards tested for safety and potency in laboratory and field experiments.

About 15,000 fowls more than 4 months old, of different foreign, native and cross-breeds, were vaccinated during 1952–62, intramuscularly with 1 c.c. dose using either 1 : 500 or 1 : 100 dilution from the desiccated material. The deaths attributable to the virus reaction after excluding other disease factors usually range from 0·5 to 1·8 per cent, according to the condition of the inoculated fowls. Some groups of the vaccinated fowls, each of more than 100, were immunized without any resultant mortality.

Immunization of 2–4 month old chickens was attempted using the intra-ocular and the intra-nasal routes of inoculation without so much success. The wing web method was consequently tried with satisfactory results. More than 5,000 of the young chickens were vaccinated with 2-stabs dose, applying the Liderly-model stab, using either 1 : 100 or 1 : 60 dilution from the desiccated material by pricking through the fold of the wing web, with safe and excellent immunizing results.

Active immunity starts in 48 hr., becomes complete in 2 weeks after inoculation, covering approximately 80–98 per cent of the vaccinated birds. Immunity proved to persist for 16 months in about 60 per cent of the vaccinated birds, and might be prolonged for the life-time in some of them.

This new vaccine proved to have remarkable advantages compared with the oil-base inactivated vaccine, since it has a highly antigenic potency producing solid lasting immunity; also it is easy to be prepared, preserved and applied. Furthermore, it is portable and can be issued to remote places without losing its efficacy or potency. Its cost is negligible compared with that of the oil-base inactivated vaccine.

SOIL SCIENCE

Biological Destruction of 2,3,6-Trichlorobenzoic Acid in Soil

Those herbicides which are composed of elements not intrinsically toxic are mostly broken down in the soil sufficiently rapidly for them to constitute no hazard to crops grown in the season following their use at selective dosages. Destruction by micro-organisms is often assumed responsible and has, in the case of phenoxyacetic acids and some other compounds, been clearly proved[1,2].

2,3,6-trichlorobenzoic acid has been found much more stable in the soil than most herbicides[3,4], and it has been questioned whether loss other than by leaching[4] or reaction in the crops or weeds[5] occurs.

We therefore carried out experiments on a sample prepared by our colleague, Dr. G. F. Laws, incorporating chlorine-36 generally distributed in the 2,3,6 positions. The purity of the sample was confirmed by radio assay on crystals and mother liquor after addition of an authentic non-radioactive specimen and crystallization from water. All subsequent radio assay procedures were calibrated from the standard stock solution used for the tests, ionic chloride being obtained by conventional micro-combustion.

1 kg of treated soil was agitated with 1,000 ml. of 50 per cent aqueous methanol containing 0·5 per cent sodium nitrate and filtered. The process was repeated with two further volumes of 750 ml. Filtration was much quicker than from water only and yielded less yellow resinous matter on evaporation. The combined filtrate was made alkaline with caustic soda and reduced to small volume by evaporation at reduced pressure in a steam-heated stripping still. The concentrated extracts were acidified with nitric acid and shaken with ether.

Ether layers were evaporated on to filter paper cylinders and assayed in an annulus counter. The papers were then extracted by aqueous alkali and a standard weight of pure inactive 2,3,6-trichlorobenzoic acid was added to the extract, which was then acidified and allowed to crystallize. The crystals were collected on a 1·2-cm diameter circle of Whatman No. 42 paper, dried, weighed and assayed at an end-window counter to determine the amount of unchanged starting material.

The original aqueous liquor after ether extraction was treated with excess silver nitrate solution. The contaminated precipitate was not easily filtered and was therefore centrifuged, dissolved in aqueous ammonia and reprecipitated by nitric acid before filtration and assay at the end window for ionic chloride. The counting-rate for standard radio ionic chloride was found not to be significantly lowered by total weight of silver chloride on the filter if this did not exceed 100 mg. The amounts precipitated from soil extracts were all below this.

The procedure applied to freshly treated soil gave about 80 per cent recovery and no radioactivity was found in any fraction except unchanged starting material. No significant radioactivity was found in the ionic chloride from soils sterilized before storage or stored frozen. The highest yield of radioactive chlorine in ionic form was 60 per cent of that supplied initially in covalent form. This was obtained after 5 months in fen soil. Mostly the yields were between 30 and 50 per cent at 1, 2 and 5 months. Erratic variation between samples was too great to provide evidence of bacterial adaptation leading to accelerated decomposition or of systematic variation of rate over dosages corresponding to between 1 and 16 oz. per 2″ acre.

The recrystallization assay indicated the ether extract in all cases to be unchanged 2,3,6-trichlorobenzoate. We found, therefore, no chlorine in an intermediate stage between this and ionic chloride. Any compound formed by opening of the benzene ring is presumably too unstable to accumulate.

Total recoveries varied from 35–100 per cent so that significant activity was often not accounted for, but the conclusion is certain that destruction of the 2,3,6-trichlorobenzoic acid molecule does occur in a biologically active soil.

FORTHCOMING EVENTS

*(Meetings marked with an asterisk * are open to the public)*

Monday, September 24

Society of Chemical Industry, Food Group (at Church House Westminster, London, S W 1), from 9 30 a m to 5 p m —International Symposium on "Food Regulations in Relation to International Trade"

Tuesday, September 25—Thursday, September 27

Institute of Physics and Physical Society (at Imperial College of Science and Technology, London, S W 7)—Introductory Seminar on "The Theory and Practice of Thermal Neutron Scattering Diffraction, as Applied to the Study of Solids and Liquids', followed by a one-day conference on current neutron work

Tuesday, September 25

Society of Instrument Technology, Control Technology Section (at Manson House, 26 Portland Place, London, W 1), at 5 p m —Exposition—"Control Applications of Static Switching"

Wednesday, September 26

British Institution of Radio Engineers, Television Group (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W C 1), at 6 p m —Discussion on "The Technical Implications of the Report of the Committee on Broadcasting"

Institute of Fuel (at the Institution of Civil Engineers, Great George Street, London, S W 1), at 6 p m —Dr J Burns Presidential Address *

Institute of Information Scientists (at the Swedenborg Society Hall, 20 Bloomsbury Way, London, W C 1), at 6 15 p m —Mr R A Fairthorne and Mr J Farradane "Information Retrieval in America To-day" *

Oil and Colour Chemists' Association, London Section (at Manson House, 26 Portland Place, London, W 1), at 7 p m —Mr A C B Matthews "The Use of Heat to Accelerate Drying"

Thursday, September 27

Institution of Mechanical Engineers, Railway Engineering Group (at 1 Birdcage Walk, Westminster, London, S W 1), at 10 a m —Convention on "Braking"

Thursday, September 27—Friday, September 28

Society of Chemical Industry, Plastics and Polymer Group (at the Institution of Electrical Engineers, Savoy Place, London, W C 2)—Symposium on "Techniques of Polymer Science"

Monday, October 1

Society of Engineers (at the Geological Society, Burlington House, Piccadilly, London, W 1), at 5 30 p m —Mr A J Davenport "Plastics as a Structural Material"

Society of Chemical Industry, London Section (at 14 Belgrave Square, London, S W 1), at 6 30 p m —Scientific Films

Monday, October 1—Tuesday, October 2

Plant Phenolics Group and the British Mycological Society (at the School of Pharmacy, Brunswick Square, London, W C 1) at 10 a m daily—Symposium on "Fungi and their Metabolites"

Monday, October 1—Wednesday, October 3

British Society of Rheology (at the Hotel St George, Harrogate) —Symposium on "The Rheology of Emulsions"

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned

Research Assistant (with a university degree, preferably in history, geography or other appropriate subject, and with an interest in maritime affairs) at the National Maritime Museum, Greenwich—Civil Service Commission (2), Burlington Gardens, London, W 1, quoting 5538/62/7 (September 27)

Assistant Librarian (graduate) in the University Library—The Secretary of the University, Northcote House, The Queen's Drive, Exeter (September 28)

Assistant Lecturer in Chemistry within the Department of Physiology—The Secretary, Royal Veterinary College (University of London), Royal College Street, London, N W 1 (September 29)

Lecturer (man or woman, with good academic qualifications, and preferably school experience) in Geography—The Principal, Avery Hill Training College, Bexley Road, Eltham, London, S E 9 (September 29)

Research Assistant (university graduate, either biologist with biophysical training or a physicist with biological interests) in the Wellcome Laboratories of Pharmacology, for investigations into the effects of hormones on the permeability of membranes—The Secretary, The University, College Gate, St Andrews (September 30)

Senior Lecturer in the Department of Veterinary Bacteriology—The Secretary, The University, Edinburgh (September 30)

Lecturer or Assistant Lecturer in Mathematical Economics—The Registrar, The University, Sheffield (October 1)

Scientific Officer (unestablished) (with a first- or second-class honours degree or equivalent in mathematics or science), for work in a section dealing with information and publicity through exhibitions, press, etc , secretarial work for home and European scientific committee, patents and general central administration on scientific matters—The Director, Building Research Station, D S I R , Garston, Watford, Herts, quoting BRS 47S (October 1)

Senior Experimental Officer (with a sound knowledge of electronics, a working knowledge of chemistry, and ability to accept responsibility) in the Department of Chemistry, to initiate and supervise the design and development of electrical, mechanical and glass equipment of all types for use in chemical laboratory research, and to assist in the control of technical staff in the department—The Registrar, Manchester College of Science and Technology, Manchester, 1 (October 1)

Electron Microscopist, Scientific Officer or Senior Scientific Officer (with a first- or second-class honours degree in chemistry or physics with postgraduate research experience in X-ray or electron diffraction, and with a good knowledge of diffraction theory as applied to structural crystallography) in the Department of Pedology—The Secretary, The Macaulay Institute for Soil Research, Craigiebuckler, Aberdeen (October 5)

Lecturer in Pharmacology—The Secretary, University College Gower Street, London, W C 1 (October 8)

Research Assistant (graduate, preferably in biochemistry with a special interest in pharmacology), to continue investigations concerned with the isolation of a polypeptide from urine which inhibits gastric secretion—The Professor of Pharmacology, University College, Gower Street, London, W C 1 (October 8)

Senior Assistant Librarian (graduate, with experience in librarianship, preferably in a university library)—The Registrar, University of East Anglia, 4 Cathedral Close, Norwich, NOR 16 P (October 8)

Lecturer in Psychology—The Secretary, The University, Aberdeen (October 10)

Lecturer (with a good honours degree and preferably a higher degree, and also a special interest in structural geology, mineralogy and petrology) in Geology—The Secretary, Sir John Cass College, Jewry Street, London, E C 3 (October 10)

Lecturer in Applied and Industrial Microbiology in the Department of Chemical Engineering—The Secretary, University College, Gower Street, London, W C 1 (October 15)

Lecturer in the Department of Pathology—The Secretary, The University of Edinburgh, Edinburgh (October 15)

Lecturer or Senior Lecturer (with teaching and research experience in pharmaceutical chemistry, and preferably with working experience in the field of chemical mechanisms of drug action) in Pharmaceutical Chemistry at the University of Sydney, Australia —The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S W 1 (October 15)

Senior Lecturer in Pharmacology at the University of Melbourne, Australia—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S W 1 (October 15)

Senior Lecturer or Lecturer (with an interest in electrical communications) in Electrical Engineering at the University of the West Indies—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W C 1 (October 15)

Plant Anatomist (with at least a university honours degree with botany as a major subject, and at least two years research experience in some field of plant morphology or anatomy) in the Division of Plant Industry, Commonwealth Scientific and Industrial Research Organization, Canberra, A C T , Australia, to collaborate in research on the floral histogenesis of the monocotyledons—Chief Scientific Liaison Officer, Australian Scientific Liaison Office, Africa House, Kingsway, London, W C 2, quoting Appointment No 130/556 (October 20)

Senior Lecturer or Lecturer in Chemical Pathology and Medicine—The Dean, St Thomas's Hospital Medical School, London, S E 1 (October 22)

Lecturer or Senior Lecturer in Biochemistry in the Faculty of Medicine, University of Western Australia—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S W 1 (October 27)

Lecturer (preferably with an interest in systematics and anatomy) in Botany in the School of General Studies, Australian National University—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S W 1 (October 29)

Chair of Biology in the School of Biological Sciences—The Registrar, University of East Anglia, 4 Cathedral Close, Norwich, NOR 16P (October 31)

Senior Research Officer (medical or science graduate with experience in medical entomology) attached to the Department of Microbiology in the Medical School, for whole-time research on arthropods of medical importance found in New Zealand and the Pacific Islands to the North—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S W 1, or The Registrar, The University of Otago, Dunedin, New Zealand (New Zealand and London, November 1)

Agricultural Economist (with experience in tropical agriculture and a genuine interest in the problems of developing countries), for a technical assistance appointment in the Federation of Malaya, to make a detailed survey and analysis of land use among aborigines—The Director of Recruitment, Department of Technical Co operation, Sanctuary Buildings, Great Smith Street, London, S W 1, quoting RC 213/87/02

Assistant Lecturers (2) (with a good honours degree) in Microbiology—The Secretary, The Royal College of Science and Technology, George Street, Glasgow, C 1

Assistant Professor (preferably with a Ph D in physiology) of Physiology—Prof L B Jacques, Department of Physiology and Pharmacology, University of Saskatchewan, Saskatoon, Canada

Biochemist to work in the Department of Surgery on problems associated with the use of chemotherapy in the treatment of cancer—The Registrar, The University, Bristol 8

Curator in the Geology Department—Head of the Geology Department, Chelsea College of Science and Technology, Manresa Road, London, S W 3

Educational Psychologist (with an honours degree in psychology or equivalent qualification with appropriate clinical training, preferably with teaching training and experience) for the Hertfordshire Child Guidance Service and Associated School Psychological Service—The County Education Officer, County Hall, Hertford

Head (with good academic qualifications, and teaching and research experience) of the Department of Physics, Grade III, West Ham College of Technology, Romford Road, Stratford, London, E 15—Chief Education Officer, Education Department, 95 The Grove, Stratford, London, E 15

Physicist or Physiologist (with a good honours degree) for postgraduate research in pulmonary physiology—The Finance Officer, London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W C 1

Plant Nematologist (under 45, with several years research experience in plant and soil nematology) in the East African Agricultural and Forestry Research Organization, to take charge of the Plant Nematology Division—The Director of Recruitment, Department of Technical Co-operation, Sanctuary Buildings, Great Smith Street, London, S W 1, quoting T/RC 264/348/05

Principal Lecturer (with a university degree and preferably a corporate member of the I E E , with teaching and industrial experience) in the Department of Electrical Engineering and Electronics, with special responsibility for the field of electrical machines and power—The Academic Registrar, Brunel College, Woodlands Avenue, Acton, London, W 3

Registrar (graduate) of the University of Essex—The Vice-Chancellor, University of Essex, c/o Education Office, County Gardens, Rainsford Road, Chelmsford, Essex

Research Assistant (Academic) (preferably with previous research experience in vacuum physics, optics, spectroscopy or electron-optics), for a programme of research in ultra-violet interference spectroscopy for space research employing image tube detectors—Dr D J Bradley, Physics Department, Imperial College of Science and Technology, London, S W 1

Research Associate in the Institute of Education, to assist with a study of relations between universities and the general public—Prof M V C Jeffreys, Education Department, University of Birmingham, Edgbaston, Birmingham 15

Research Students (2) in Solid State Physics to study semiconducting compounds of interest for thermoelectric applications—Prof D A Wright, Department of Applied Physics, The University, South Road, Durham

Statistician (with a first- or upper second-class honours degree, together with an interest in biological research) in the Department of Biometrics—The Secretary, Grassland Research Institute, Hurley, Maidenhead, Berks

Tutor (graduate with good teaching experience) in Mathematics and/or Physics—The Bursar, College of Air Training, Hamble, Southampton

Woman Graduate (with a degree in geology, and preferably with research experience and artistic ability), to have special responsibilities for museum display under the Curator of the Geological Collections—Mr J M Edmonds, University Museum, Oxford

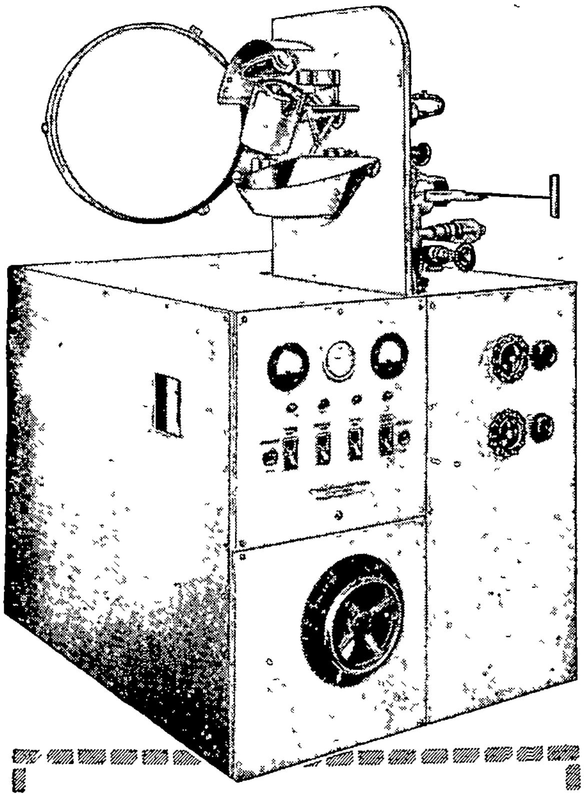
WILD BARFIELD NRC*

Laboratory Vacuum Furnace



Model 2904

2 lb. to 8 lb. capacity

(FOR OPERATION UP TO 2,000°C)

Made in Britain to the designs of the National Research Corporation of Mass., U.S.A. who have built more high vacuum furnaces now in successful operation than any other firm in the world. The Model 2904 Vacuum Furnace is a self-contained unit for high-temperature operation at high vacuum or under controlled atmosphere. It is heated by a tungsten resistance heating element with molybdenum heat shields in a water-cooled stainless steel sleeve.

This permits:

- Close control of temperature
- Good heat distribution
- Long life
- No outgassing or contamination from refractories

FOR MELTING • POURING • SINTERING
ALLOYING • HEAT-TREATING • ANNEALING

Vacuum Arc and Vacuum Induction Furnaces
Vacuum Analysis Equipment • Vacuum Diffusion Pumps

STANDARD EQUIPMENT

- High vacuum pumping system with Wild Barfield-NRC oil diffusion pump and Gas Ballast mechanical pump
- Metal cabinet base, overall dimensions 35" x 43" x 34" high.
- Pyrex bell jar, 18" diameter x 12' long, protected with a wire mesh guard, or optionally a stainless steel bell jar
- Water-cooled basin to shield the bell jar and to catch spilled metal
- Feed-through for thermocouple wires or heater leads for special work
- 15 kW power supply, controlled with a variable auto-transformer. Power is supplied to the split tungsten sleeve through water-cooled coaxial leads

* NRC *is the trade-mark of the National Research Corporation, registered in the United States Patent Office*

IMPERIAL COLLEGE OF SCIENCE AND TECHNOLOGY

PHYSICS DEPARTMENT

Applications are invited for the post of Research Assistant (Academic) for a programme of research in ultra-violet interference spectroscopy for space research employing image tube detectors Previous research experience in vacuum physics, optics, spectroscopy or electron-optics desirable but not necessary The appointment is for three years, but a temporary one year appointment would be considered for a suitable candidate Salary in range £960 to £1,100, with F S S U and Family Allowances

Applications, with full details including the names of two referees, should be sent as soon as possible to Dr D J Bradley, Physics Department, Imperial College, London, S W 7

WAR DEPARTMENT

MAIN GRADE PROFESSIONAL ENGINEER

Duties To take charge of a sub-unit developing computer methods for the production of scales of spares required for the repair and servicing of Army equipment The sub-unit is at present located at Woolwich, using EMIDEC equipment to produce basic punching documents for programmers working at Donnington , in 1963 the sub-unit will be moved to Donnington Qualifications A M I Mech E or A M I E E, a recognized engineering apprenticeship, and, preferably, several years' experience on the repair and modification of Army Equipments plus at least five years' experience on the repair of electrical and electronic equipments Salary Scale (Woolwich) £1 574 to £2,088

Application forms from War Office, C 13B(1), Northumberland House, W C 2, to be completed and returned not later than October 8, 1962 (5)

LEVINGTON RESEARCH STATION

Director J A Storrow, M Sc Tech , Ph D , D Sc (Manch), M I Chem E

A vacancy exists in the Fundamental Research Section at Bramford Development Station for a

RESEARCH SCIENTIST

to study fundamental processes including the handling, heating, cooling, and drying of discrete solids The physical behaviour of mixtures of air and solids flowing in ducts is of particular interest The approach could be either experimental or mathematical A research degree in a physical science is required, preferably with some subsequent research experience

Bramford Development Station situated near Ipswich, is concerned with fundamental studies and pilot plant It is part of Levington Research Station, the research department of Fisons Fertilizers Limited

The salary offered will depend on qualifications and experience, and there is a contributory pension and widows' pension scheme

Applications, giving qualifications and experience, should be made to

Personnel Manager (MI10),
Fisons Fertilizers Limited,
Harvest House,
Felixstowe,
Suffolk

RESEARCH VACANCIES

BENGER LABORATORIES LIMITED,

an ethical pharmaceutical company, is expanding its Research and Development Department and has the following vacancies

BIOLOGICAL SCREENING SECTION

TWO GRADUATE PHARMACOLOGISTS who will be concerned with the evaluation of potential new drugs Preference will be given to graduates in Pharmacology or Physiology who have had several years' experience in practical pharmacology

TWO TECHNICIANS to assist in the PHARMACOLOGY subsection Preference will be given to applicants who possess a recognized qualification in laboratory work and who have had experience of practical techniques Consideration will also be given to school-leavers who have obtained G C E at advanced level in at least two science subjects and who wish to embark on a career in biological research

ONE ELECTRONICS TECHNICIAN. The vacancy is for a suitably qualified man to be responsible for servicing and maintaining electronics apparatus and for constructing new equipment in the biological laboratories Workshop facilities will be provided Experience in RF techniques will be an advantage

ONE GRADUATE with qualifications in bacteriology or allied sciences to assist in the BACTERIOLOGY sub-section

ONE TECHNICIAN to assist in the PARASITOLOGY subsection Experience of Helminthology is desirable

PHARMACEUTICAL FORMULATIONS SECTION

TWO QUALIFIED PHARMACISTS to work in the Pharmaceutical Formulations Section Previous experience in this type of work would be an advantage

The Company is a member of the Fisons Group of Companies and Group Contributory Pension Schemes are in operation The Company works a five-day week and conditions of work are excellent

Applications, which will be dealt with in confidence, should be sent to the

Secretary
BENGER LABORATORIES LIMITED,
Holmes Chapel, Cheshire.

UNIVERSITY OF MANCHESTER

Applications are invited for the post of Lecturer in Genetics in the Departments of Botany and Zoology in the Faculty of Science Candidates should have a wide interest in the subject so as to be able to lecture to students of both departments Duties to commence as soon as possible Membership of F S S U and Children's Allowance Scheme Salary on a scale £1,150 to £1,950 per annum, initial salary according to qualifications and experience

Applications should be sent not later than October 26, 1962, to the Registrar the University, Manchester, 13, from whom further particulars and forms of application may be obtained

UNIVERSITY OF BIRMINGHAM

DEPARTMENT OF MEDICAL BIOCHEMISTRY AND PHARMACOLOGY

Applications are invited for Research Associateships or Fellowships with the following duties respectively (i) to carry out ultrastructure studies on nerve myelin degeneration , (ii) to assist in histological and cytological studies on the intestinal mucosa, with particular reference to absorption , (iii) to assist in histological and cytological studies of low grade tissue damage (chronic toxicity)

Applications should be sent to Professor A C Frazer, Department of Medical Biochemistry and Pharmacology, The University, Birmingham 15

UNIVERSITY OF NATAL

DEPARTMENT OF GEOLOGY

Applications are invited from suitably qualified persons for appointment to the post of Senior Lecturer in Geology (Petrology) Durban, on the salary scale R 3,180 by R 120 to R 4,140 (£1,590 by £60 to £2,070) per annum The commencing notch will be dependent on the qualifications and/or experience of the successful candidate, who will be expected to assume duty on January 1, 1963, or as soon as possible thereafter

Application forms and further particulars of the post, including commencing dates, leave conditions, staff bursaries, etc , are obtainable from the Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S W 1 Applications close in South Africa and London on October 15, 1962

LABORATORY TECHNICIAN REQUIRED to assist in biochemical research on the biosynthesis of proteins Two passes in an experimental scientific subject at Advanced level G C E or Associateship of I M L T or equivalent qualification required Salary, for suitable applicants, on Whitley Council Medical Laboratory Technician scale (£750 to £850 per annum) —Applications to Dr P N Campbell, Courtauld Institute of Biochemistry, The Middlesex Hospital Medical School, London W 1

CALCUTTA

PRIVATE FOUNDATIONS AND THE SCIENTIFIC ERA

THE seventeenth annual report of the Nuffield Foundation, covering the year ended March 31, 1962, which for the most part deals with projects in fields in which the Foundation has worked for many years, is of special interest as illustrating the flexibility which is one of the most valuable features of the programmes of the private foundations* The introduction to the report itself directs attention to this feature of the Foundation's work, noting how in the first few years after the War grants for research in the physical sciences, notably in nuclear physics, figured prominently in the Foundation's activities, until the university departments concerned became fully established and began to attract sufficient permanent finance Then the Foundation, a few years back, noted the opportunity for substantial support of fundamental researches in biology, then much narrower in scope than it is to-day Now the subsequent progress in biological science and the growing support it can claim allows the Foundation to look elsewhere for growing points to be nurtured, and this year it has initiated a large-scale programme which it hopes will lead to improvements in the teaching of school science and mathematics

Over the years the Foundation has made grants for educational research and experiment totalling nearly £300,000 and covering general surveys of university, technical and adult education, sociological studies of teachers and pupils in schools, some broadly psychological investigations, and work on curricula and teaching methods During 1961–62 alone the Foundation allocated some £340,000 for this purpose, reflecting the criticism of the Crowther Report and a memorandum of the Parliamentary and Scientific Committee of the inadequacy of the present national expenditure on educational research, as well as the Foundation's growing interest in education and the existence of people able and willing to try out new ideas in school teaching The greater part of this sum —£250,000—has been allocated to a comprehensive long-term programme on the teaching of science and physics, concentrating initially on five broad sections, the Foundation acting as prime sponsor and co-ordinator, but collaborating fully with other interests in this field

The five sections chosen as starting-points are first, physics for 11–15-year-olds, second, chemistry, third, biology for the same age groups, fourth, secondary school mathematics, and fifth, primary and secondary school science in general The aim in the first three sections will be to provide a complete range of aids in physics, chemistry and biology, designed by teachers for teachers in the first four or five years in grammar schools, and the upper streams of some secondary modern schools, and the programmes will be based on, and are intended to consolidate, the work which has already been done in revising school science curricula The physics project is already under way and is expected to be complete within three years Concurrently with the general science teaching programme, a grant of £1,000 has been made to enable the physics masters at King's College School, Wimbledon and Westminster School to spend four weeks working with the senior science master at Malvern College in the development of new ideas in the teaching of modern physics

The informed interest aroused by the small experiment which the Foundation fostered in the teaching of French at primary-school level at East Ham Grammar School for Boys and Talbot County Primary School, Leeds, has encouraged the Foundation to support a proposal from the Ealing Technical College for developing rapid language courses for adults The proposal fits in well with the Foundation's general interest in language teaching, and a grant of up to £26,200 over three years has been offered The aim is to produce materials for a full-time course of from 8 to 10 weeks duration which would give the adult beginner an understanding of the language—initially German and Spanish—and enable him to use it for most general purposes Another grant of £14,000 over six years has been made to the Institute of Education, University of London, towards an extended inquiry by the Reading Research Unit into the effectiveness of using an augmented alphabet in teaching children to read A grant of £45,000 was also made towards the building of a graduate house at Somerville College, Oxford The supplementary grant of £8,500 made to the Department of Anatomy, University College, London, largely for necessary units in connexion with the use of the learning computer, further illustrates the Foundation's interest in new educational developments

Two other illustrations of the value of flexibility are to be found in this report The Foundation was early concerned with the health of people at work, and in its first decade did much to establish the study of industrial health as an academic discipline, it also helped to set up the first practical experiments in group health schemes for smaller factories and to provide an occupational hygienic service for industry. Time was needed for these innovations to prove their worth, and meanwhile the Foundation's interest in industrial health lay dormant In 1960 it was actively revived, whereupon the Foundation allocated £250,000 for new developments in this field, and industry's present receptive attitude to industrial health schemes indicates that the Foundation's renewed support has been given at the right time The present report records the offer of a temporary grant of £20,000 over five years for the establishment by Prof R E Lane, professor of occupational hygiene, within the University of Manchester of an occupational hygiene unit to serve the needs of industry in north-west England and Wales, on the assumption that the unit will become self-supporting by the fifth year £60,000 has also been promised for capital needs and recurrent expenses on a tapering basis to experiments in Rochdale and in Dundee in establishing group health schemes for local firms

---

* The Nuffield Foundation Seventeenth Report for the year ended 31 March, 1962 Pp xiv+159 (London The Nuffield Foundation, 1962) (see also p 1,258 of this issue)

The second illustration is to be found in the work of the Foundation overseas While at the end of the present year the Foundation decided that, since South Africa had chosen to leave the Commonwealth it could not continue the special help it had been giving to the Union, the overall needs of Commonwealth territories are of lasting concern Existing schemes, mainly for research and training, will be run down during the next twelve months, after which the Foundation must regard South Africa, so far as eligibility for grants is concerned, on the same footing as other non-Commonwealth countries, and, although the Foundation is glad to have made a significant contribution to the development of the universities in South Africa, the free universities, in their stand for academic privileges and standards, will not wish it otherwise

In its overseas work to-day the Foundation rightly recognizes, however, that the newly developing countries have a major claim It is difficult to exaggerate the size and diversity of their need, and although no private foundation, however large its resources, can make much direct impression on the economic conditions, sound judgment in choosing the right projects can be of decisive effect Here, too, the selection of the growing points is what matters, and, in his Chancellor's lecture to the University of the Witwatersrand last April, Sir Eric Ashby indicated how wide a field there is for experiment with educational schemes and local community development The Foundation's interests in the developing countries are very much determined by the effective application of the principle of self-help, and of this the Centre for Educational Television courses towards which the Foundation has matched a Government contribution of £100,000 with a like sum, to be made available to the Centre over five years, are an outstanding example

In this connexion the grant of £30,000 a year for three years which the Foundation has made to the Overseas Development Institute should be mentioned, the Anglo-American study on general development problems which the grant is to support is concerned with the problems of emergent countries and the aid that might be given them and derives much of its value from its unofficial character

Of grants totalling more than £190,000 in 1961–62 for the Commonwealth Overseas it is pertinent to note that the Foundation has offered £4,000 to the Inter-University Council for Higher Education Overseas for the first year of a scheme for training technicians of overseas university institutions, in the hope that thereafter the Department of Technical Co-operation will support the scheme £50,000 has been set aside over three years towards the expenses of an organization concerned with the development of improved materials and curricula for African schools, a grant of £34,100 has been made to the University College of Rhodesia and Nyasaland for fundamental research at Lake Kariba, in co-operation with the University of the Witwatersrand, and also, it is hoped, in association with the zoology department of a university in Great Britain, covering the physical and chemical states of the water, the biology of the phyto- and zoo-plankton, and the biology of the invertebrate fauna and of particular plants A grant of £16,000 over five years has been made to enable Prof W J M Mackenzie of the Department of Government at the University of Manchester to assist in developing teaching and research in public administration in East Africa, particularly by creating a link between work in that field in Manchester and in Nairobi

Three other grants, also to Africa, are also particularly significant in this same connexion A grant of £12,500 has been made to the African Medical and Research Foundation covering the cost of fifty high-frequency radio sets to enable the Foundation to connect outlying district and mission hospitals in remote areas with headquarters With the Gulbenkian Foundation, the Nuffield Foundation is sponsoring a scheme of the Royal Commonwealth Society for the Blind for the education of blind children in Nigeria, providing £15,000 over the period from July 1962 to December 1965 by which time it will be locally self-supporting The investment could bring about a spectacular advance in the education of handicapped children, and if the scheme is successful in Nigeria it may provide a pattern for the education of blind children in other emergent Commonwealth countries

The third project also meets a need that has become acute since African territories reached independence A grant of up to £8,500 over three years to the Department of Zoology, Fourah Bay College, is to enable the College to pay the extra salaries involved in taking over the Fisheries Research Laboratory in Freetown, Sierra Leone, on the understanding that the College would finance these posts after 1964 There is at present no marine biological research activity between Dakar and Accra, and the position of Freetown on the sea and estuary makes it particularly suitable for the study of tropical marine biology Trained marine biologists are greatly needed in Africa, and the grant may also make it possible for the Department to develop research into fishing resources, about which little is known

In so far as this project may eventually contribute a valuable addition to the diet of the population in the shape of fish protein, it may be set beside a fourth project—the grant of £17,500 over three years to the Scientific Research Council of Jamaica in support of a Leaf Protein Unit set up by that Council to develop the production of protein from local leaves What is worth noting is that the Foundation is giving vital help in fields where the Governments of newly independent territories have largely failed to appreciate the significance of research or been unable as yet to find the necessary resources Long-term research is particularly liable to suffer in this situation, and the lead which the Nuffield Foundation is giving should be noted also by the Overseas Research Council and the Department of Technical Co-operation

There is a further kind of interest of the Foundation which is noted specially in the introduction to this report which equally illustrates the unique value of the independent foundation in the world of to-day This lies in new ventures which have as yet no practical expression When such a new direction of interest is established the Foundation must often wait its opportunities and seek out the right people, it may be necessary first to test out ideas on a small scale, while at other times a major concern may develop very rapidly The Foundation must be ready to seize such an opportunity and back a favourable judgment with adequate support, and it therefore welcomes, and encourages, the flow of ideas and proposals which come to it from outside This seventeenth annual report of the Nuffield Foundation fully demonstrates how invaluable a place the private foundation has in discovering and fostering the growing points in society to-day It can take risks which no Government institution could wisely do and which even the university might hesitate to accept—even if it had the resources No expansion of Government support for research and development or modification of Government organization in that field is likely to diminish, still less eliminate, the need for such pioneering, its emphasis on response enables the Foundation to do something that is much more difficult for a Government body to attempt

THE SUN DURING THE INTERNATIONAL GEOPHYSICAL YEAR

I G Y Solar Activity Maps, *D* I, and *D* II

Annals of the International Geophysical Year, Volumes 21 and 22 (International Council of Scientific Unions—Comité International de Géophysique) 1,116 maps (London and New York Pergamon Press, 1961) £54, 150 dollars

WHAT might very roughly and a little misleadingly be called solar meteorology, the study of all kinds of changes on the surface of the Sun, began in a primitive way some centuries ago with the observation of sunspots It was not, however, until the nineteenth century that much real progress was made in systematizing the results, and not until the twentieth that the close connexion between events on the Sun and subsequent events on the Earth began to be understood Some of the essential techniques are more recent still The Lyot filter did not come into general use until the 1930s, and radio-astronomy was virtually unknown until the middle 1940s Our appreciation of some of the related phenomena, for example, of cosmic rays, also depends on rather recently acquired knowledge

We now have a picture of a Sun in which somehow powerful magnetic fields are transported piecemeal to the surface, in a kind of 11-year tide, and where these fields produce, or have associated with them, not only sunspots but also a number of other phenomena flares, coronal changes, etc These in turn produce, or are associated with, irregular enhancements of radiation in the far ultra-violet and in the radio spectrum, sometimes of cosmic rays, too, and are accompanied by the ejection of clouds of ionized gas with velocities from hundreds to a thousand or more kilometres per second Some of these gas particles reach the vicinity of the Earth, giving rise to magnetic storms, auroræ, changes in the ionosphere, etc Within recent years the rise of artificial satellite research, and the possibility of manned flight outside our atmosphere, have stimulated much interest in what happens in interplanetary space during these disturbances

Some ten years ago, when plans were being made for the International Geophysical Year of 1957–58, it was natural to include an intensive campaign to record as completely as possible all events open to our inspection on the solar surface Routine solar observations, in contrast to many geophysical measurements, are prone to serious interruption from the alternation between day and night and from the weather, so that to obtain a solar record sufficiently continuous to give good correlations with geophysical data it is necessary to organize world-wide co-operation between observatories Further, after the observatories have done their part, the data have to be collected and published in some concise and convenient form, if they are to be of real value All this has been done, and we have here, edited by Dr M A Ellison, Volumes 21 and 22 of *Annals of the International Geophysical Year* They consist of two large filing cases, each containing for each day of the period from July 1, 1957, to December 31, 1958, a loose sheet on which the observed features of the surface of the Sun are entered in simple outlines of various colours, according to a given code

The diameter of the solar image on these maps is 15 cm and, to avoid confusion in the reproduction, heliographic co-ordinates (which are essential for the effective use of such maps) are provided, not on the maps themselves but on transparent sheets, in the form of a set of the well-known Stoneyhurst disks The appropriate sheet is selected from figures given on the *D* I maps

The maps of the first set (*D* I, Volume 21), the production of which was supervised by the High Altitude Observatory, Boulder, Colorado, give sketches of sunspot umbræ and penumbræ, mainly from the routine observations made regularly at Zurich and Locarno, and the outlines of calcium plages from observations made for the most part at the Crimea, Kodaikanal, Arcetri and McMath solar observatories In addition, flares observed in Hα light, of importance 1 + or greater on the usual scale, are entered with their position to ± 1°, and with their time of occurrence and importance This flare record is based on very numerous Hα patrol photographs provided by 26 stations located all over the world Finally, the *D* I maps also give all available information about active prominences and surges (A surge prominence is observed as a column of material expanding more or less radially outwards from the Sun and then returning along the same path, an intriguing and imperfectly understood phenomenon best seen on motion picture films)

In the *D* II maps of Volume 22, prepared at the Fraunhofer Institute, Freiburg, Germany, there is a similar presentation of sunspot *groups* (from daily maps prepared by the Fraunhofer Institute), giving their positions, magnitude, Zurich classification and the number of individual spots in the group. Limb prominences, disk filaments and indications of 'sudden disappearances' (of filaments or prominences) are also given, all based on observations in Hα with either Lyot filters or spectroheliographs. Around the disk, at intervals of 5°, intensities of the coronal green line, 5303 Å, are plotted in the usual convention in which distance from the limb is proportional to intensity. Another transparent disk is provided for reading off these intensities conveniently. The original measures, made at nine different observatories by slightly varying methods, refer to positions between 40″ and 1′ above the limb, and have been reduced as well as possible to a common scale. Finally, lines of equal intensity (radio isophotes) are given for 21-cm radiation, the measures being made with a multiple pencil beam, 3′ wide, at the Radio Physics Laboratory, Commonwealth Scientific and Industrial Research Organization, Sydney.

The two sets of maps cover between them most routine observations of the Sun during the International Geophysical Year which it was possible to make without too much difficulty by existing techniques. Measurements of solar magnetic fields are perhaps the most important exception and these are to be given separately in a later publication. The maps are an impressive example of what can be achieved by international scientific collaboration between five continents. They provide a permanent record of the behaviour of the solar surface during a period of very high sunspot activity, and astronomers, geophysicists and others should be able to refer to them with profit for many years to come. As is now generally agreed, it appears highly desirable to repeat many of the activities of the International Geophysical Year during a typical period of minimum solar activity. The hope is that observations made over the period April 1, 1964, to December 31, 1965, will eventually become available as an essential supplement to these volumes.

The maps are arranged and printed well. The explanatory preface is given in both English and French. The very high price is likely to restrict their sale to the bigger science institutions and libraries.

ASTRONAUTICS AND ASTRONOMY

Advances in Space Science and Technology

Volume 3. Edited by Frederick I. Ordway, III. Pp. xiii + 482. (New York: Academic Press, Inc.; London: Academic Press, Inc. (London), Ltd., 1961.) 100s.

The first two volumes of this series were entitled *Advances in Space Science*: the addition of *Technology* provides a better description of their contents, but does not imply any change in editorial policy.

Volume 3 consists of 8 papers, of which the first five form an admirable review of the solar system (excluding the Sun and the Earth), regarded as an objective for astronautical exploration. The first paper, "The Role of Geology in Lunar Exploration", by J. Green and J. R. Van Lopik, is a 110-page survey of a rather neglected subject—the proper method of study and the uses of the lunar surface materials. The second, "Venus as an Astronautical Objective", by P. Moore and S. W. Greenwood, describes the little that is known of Venus and discusses possible transfer orbits by which it might be approached. The third paper, by S. L. Hess, considers "Mars as an Astronautical Objective", outlining our present knowledge of the planet and suggesting how it might be explored. The next paper, by R. L. Newburn, jun., is a similar review of Mercury, the asteroids and the outer planets. The fifth and last paper on the solar system is a short account of interplanetary matter by E. Manring, which emphasizes the gaps in present knowledge and the need for better calibration of the instruments for detecting interplanetary dust. All these papers are well written, and together they constitute a most useful preview of the space explorer's sphere of operations.

It is interesting that three of the papers advocate observations (of Mercury, Venus and Mars) with large telescopes carried by balloons to great heights, where the 'seeing' would be better than on Earth: perhaps this logical preliminary experiment will be classed as 'space exploration' and thereby qualify for a small fraction of the vast expenditure on rocket-launched vehicles.

The last three papers are primarily technological. A. Alberi and C. Rosenkranz discuss the "Structures of Carrier and Space Vehicles" in a 120-page monograph covering everything from pre-launch loads to the properties of structural materials; though thorough, the paper is less readable than it might be, chiefly because of an overload of abstract nouns. The next contribution, short but adequate, is by W. C. Cooley on "Advanced Nuclear and Solar Propulsion Systems". The last and least satisfactory paper is on "Human Factors Aspects of Weightlessness", by P. A. Campbell. The attempts to define weightlessness are unconvincing, and the tendency to ignore non-American work is carried too far: for example, "The author is not aware of any individual who has been constantly weightless for more than a few minutes", but since the author mentions Alan Shepard's 4 min. of weightlessness in May 1961, he should have been aware of Yuri Gagarin's 75 min. in April 1961.

D. G. King-Hele

CHEMICAL ENGINEERING

Advances in Chemical Engineering

Vol. 3. Edited by Thomas B. Drew, John W. Hoopes, Jr., and Theodore Vermeulen. Pp. x + 345. (New York: Academic Press, Inc.; London: Academic Press, Inc. (London), Ltd., 1962.) 86s.

The third volume in this series appears after an interval of four years. Once again the individual contributions are of a high standard, but there does not appear to be a consistent editorial policy. Thus, the chapter on crystallization from solution would be appropriate in a general text-book on chemical engineering. It is in no sense a complete review, there being a number of surprising omissions, particularly in respect of recent work in Britain. The chapter on mixing and agitation is comprehensive, not only referring to recent work but also reviewing all the important work in the field.

High-temperature technology is a rapidly developing field in which much of the basic work has been carried out by the chemist and the physicist and may not be familiar to many chemical engineers This is the kind of subject which benefits from the treatment which can be given in a book of this type The methods of measuring and of attaining high temperatures are described in detail, and the authors look forward to fields of application which are of interest to combustion engineers and others

In much of the earlier theoretical section of the chapter on the design of packed catalytic reactors, matrix methods are used, but the advantages of so doing are not apparent, apart from brevity The authors summarize most of the recent work on velocity profiles and transport phenomena in packed beds and give practical design procedures, paying special attention to the approximations which may be introduced and the probable errors arising therefrom

In the final chapter, optimization methods are discussed The use of optimization techniques is becoming of increasing importance with the general downward trend of profit margins in the chemical industry The author discusses their application in relation to determining optimum conditions for an individual item of plant such as a chemical reactor, and for the more general problem of formulating construction and maintenance programmes to produce the maximum profit in a given period The treatment is concise and provides a necessary background for the chemical engineer concerned with either plant design or with forward planning

This volume contains much valuable material, and will be useful both to the practising chemical engineer and to the student who is taking an advanced course in any of the fields discussed J F. RICHARDSON

TREATISE ON ZOOLOGY

Traité de Zoologie

Anatomie, Systématique, Biologie Publié sous la direction de Prof Pierre-P Grassé Tome 4 (Premier Fascicule) Plathelminthes, Mésozoaires, Acanthocéphales, Némertiens Par J -G Baer, P de Beauchamp, M Caullery, L Euzet, M Gontcharoff, P -P Grassé, Ch Joyeux Pp 944+4 planches en couleurs (Paris Masson et Cie , 1961) 200 NF

THIS is the first part of the fourth volume of this well-known work It is divided into four approximately equal parts—one dealing with turbellarians, one with flukes, one with tapeworms and one with mesozoans, nemertines and acanthocephalans Nematodes and rotifers will be dealt with in the second part The authorship is French and Swiss, and is both authoritative and distinguished One has become accustomed, in earlier volumes of "Grassé", to excellent typography and illustrations, and the same high level is maintained here The volume seems to have more photomicrographs than previous ones they relate mainly to parasitic forms, and, excellent though they be, the complicated anatomy of these animals is better displayed by the beautiful line diagrams There are four coloured plates, one of polyclads and three of nemertines—one, indeed, a reproduction of McIntosh's well-known seventy-year-old figure of a tangled boot-lace worm. There are more typographical errors than one expects to find in a book of this sort they become particularly tiresome to the kind of reader that one hopes will use the book when they occur (as many do) in bibliographies. It is also disappointing to find references in the text—even as specific as "Voir en particulier Koehler—32 " (p 75)—and no corresponding bibliographical entry

This said, may it be added that the treatment is excellent, particularly in relation to parasitic groups, where the biology, life-history and evolution of an extended series of types is presented, as a zoological rather than a medical or veterinary matter. In dealing with free-living forms the approach is predominantly systematic, and many students might prefer the more comparative account by Hyman "Grassé" has never pretended to treat the physiology of animals except as an incidental, but it is disappointing that the outlook of functional morphology is so lacking—for example, of the two papers by Cowey and Clarke which make intelligible much of nemertine and turbellarian form one is not mentioned and the second receives only the briefest acknowledgment Given its own point of view, however, this is a valuable and welcome addition to zoological literature

ALASTAIR GRAHAM

GENETICS *AB OVO*

Cell Heredity

By Ruth Sager and Prof Francis J. Ryan Pp. xi + 411 + 16 plates (New York and London John Wiley and Sons, Inc , 1961) 60*s*.

MOST of the text-books of genetics published in the past decade still followed the traditional treatment set by the oldest and most persistently successful of them all Sinnott and Dunn's. This treatment started with the description of variation between individuals of a species, introduced Mendelian inheritance and its principles, went on to linkage and the chromosome basis of inheritance, branched out into the ways in which genes produce their effects and concluded with population genetics and evolution

Sager and Ryan make a brave attempt towards a novel approach they start from deoxyribonucleic acid and work their way up to the genetic control of cellular integration Because of its methodological divergence, they omit population genetics The greatest part of the book is based on examples and methods from microbial genetics The material is therefore largely of a kind which was barely represented in older text-books

This attempt deserves all respect, and most geneticists will welcome it, with minor reservations In its present form the book will be especially useful to those who—by profession or hobby—have already gone through a more traditional introduction to genetics Its usefulness lies in the wealth of well-summarized examples—though with a somewhat high rate of mistakes—from the genetics of bacteria, bacteriophages, fungi and unicellular algæ, and in its good review of the present state of knowledge on non-nuclear inheritance

Its shortcomings lie mainly in the logics of presentation and argumentation, at their weakest in the chapter on "What is a Gene ?" Yet, this same chapter will be found most useful in bringing together data on fine genetic analysis in several organisms

On the whole we have to be most thankful to the authors for taking up a difficult task, and wish them future editions in which their attempt will become as fully fruitful as it deserves to be

G PONTECORVO

SCIENCE AND WORLD AFFAIRS*

By The Right Hon Viscount HAILSHAM, Q C

Lord President of the Council and Minister for Science

IT is clear to-day that scientists have much to say to public men which the latter ought to know and perhaps do not It does not follow, however, that public men have nothing to say to scientists, or that both have not much material for mutual discussion What is clear is that the social and political problems of the day, and the technological and scientific questions are in a great degree closely related, perhaps inextricably connected, and neither the scientist nor the politician can afford either to disinterest himself in the discussions of the other, or not to feel himself wholly involved in the success of the other's attempts to solve his part of the puzzle

However, since I have come to fulfil my own part of the bargain and to consider what might be said appropriately by a Minister of H M Government on an occasion like this when distinguished scientists from many countries of the world are meeting, I almost came to repent what I had done

There is not, I believe, as yet, any genuinely scientific theory of politics Whether there ever can be I will not profess to argue, but let any who thinks that such a system would be easy to develop reflect at least that the parameters involved would be numerous and somewhat difficult to identify In the meantime, we dwell in the pre-scientific world of the craftsmanship, such as it may be, of the practical politician, and the insights, such as they may be, of the occasional political theorist

But it does not take a scientist or a politician to see, or to say, that the human race is in a state of crisis, and that, unlike all previous human crises, the nature of the crisis is such as to affect not simply human groups or institutions but the entire life and condition—perhaps the survival—of the human species in the world

For this, of course the responsibility lies on the progress of technology, the application of organized human knowledge to the processes of manufacture, distribution, transport, and the dissemination of ideas It is this which has revolutionized human life in a matter of generations, it is this which has confronted at last the widely separated branches of the human family in almost intimate contiguity after long eons of separation It is this which has organized the possibility of mass annihilation by the evolution of the sophisticated guidance systems of modern rocketry and the immensely destructive powers of modern fission and fusion

It is therefore this, and the intriguing possibility that science may afford even more challenging prospects of agreement and co-operation—a way out, as it were, of the ideological impasse through agreement on technological essentials—which can lend significance and hope to a meeting between scientists

Perhaps our most essential human characteristic is the desire to conquer our environment by conscious and co-operative effort In one sense this is what science, and in another sense this is what politics, is about But if this is so it is as well that politicans and scientists should think a little carefully about the human qualities which it is necessary to establish and encourage if the human species is to survive in what is essentially a new environment I do not think it is unscientific to do this If we are to pursue the attempt to control our environment we must surely make a serious and co-operative effort to determine the line of our own evolution, and by this I mean to include for this purpose the selection and development of the instincts and habits of mind and behaviour likely to lead to human survival I do not think this is simply a question of genetics, if it were it would be unlikely to yield quickly to scientific persuasion But as Prof P B Medawar has pointed out, human inheritance is not simply a question of genes and chromosomes, the dissemination of ideas and habits by communication in time and space themselves constitute a parallel system of genetics to the natural system, and I do not think that either scientists or politicians can exaggerate the survival value to the human species of such human characteristics as compassion, law-abidingness, rationality, patience, and what is called honesty and integrity It may be, as I think one of the American papers has recently pointed out, that in the past the so-called military virtues of courage and combativeness, the war-like instincts which are quite certainly part of our natural make-up have been essential for survival of any group whether in their contests with natural environment or in inter-tribal struggles No doubt, too, these instincts will have their properly controlled part to play in the future, since there is no reason to fear that the future will hold out any less scope for the spirit of adventure than the past But it is worth emphasizing that when what is at stake is the survival of the species, the civilized and peaceful instincts which are no less part of our natural inheritance will have a predominant part to play and will need whatever encouragement the politician and the scientist can have to offer them

When I said that there was no fully scientifically developed theory of politics, I had in mind primarily the so-called ideologies But I had also partly in mind political institutions For it is clear enough that these largely antedate the technological revolution, and derive their size and shape from factors which are only partly contemporary—the national sentiments, the geography, the economics, and the military strength of bygone generations Such as they are, they are clearly imperfectly adjusted to the actual requirements of the present age, and these very requirements are themselves altering so rapidly that to adjust political institutions perfectly to them as they are—in a state of flux and transition—would be a task almost beyond the wit of men Though this task must be attempted, it is evident that the period of adjustment will be difficult, prolonged, and continuous—another and pragmatic argument in favour of those peaceful qualities to which I have referred

Nevertheless, it is, I think, worth while to pause for a moment and survey the extent to which the imperfection of human political institutions may have an influence on the subject-matters of special interest to the supporters of the Pugwash Conferences, and on the extent to which such discussions may themselves point a way to the kind of institution which we ought to be developing

---

* Substance of the opening address on September 3 to the Tenth Pugwash Conference held in London

Pugwash discussions have in the past largely concentrated on the technical problems of disarmament and on the equally important issues connected directly with the physical sciences and world affairs I regard them as extremely valuable, nor do I wish to complain, since I regard the assumption as essential to their fruitfulness—that they have been based very largely on the assumption of the continuance of existing political institutions and of some sort of *modus vivendi* between existing political systems or, as they are called, ways of life

I do not myself, however, believe that these assumptions are necessarily correct So long as negotiations for disarmament are based on what is fundamentally the negative approach of the reduction of actual arms, and the prohibition of their manufacture or development, I do not myself believe that they will enjoy complete success What I believe is required for complete disarmament is a recognition by the opposing powers not simply of the dangers of the continuance of the present arms race, but of a prior need for co-operation in projects as exciting and as expensive as the struggle to maintain the uneasy balance of terror which constitutes at present our somewhat precarious guarantee of peace In other words, I would like to see the Communist and the Western World agree to spend a proportion of their national income not less than they are now spending on arms and defence on ascertainable projects of a different order—internal and external—education, building, research, civil engineering, agriculture, and health The inspection and verification of these programmes could not present the difficulties to national security envisaged by the present disarmament negotiations, and if they were expensive enough and actually undertaken, preferably in co-operation, they would offer a fairly definite guarantee that disarmament would proceed

At the same time I am not myself prepared to proceed on the assumption that our present pre-scientific political institutions are necessarily to be regarded as immutable for all time or changeable only under the pressures, sometimes logical, and sometimes fortuitous, of events

I hope I shall not be regarded as one of those who regard war as an ineluctable biological necessity But I wish that more politicians and more scientists would examine the hypothesis to which I myself incline, that it is the invariable *sequela* of wholly independent and separate sovereignties, in close physical association with one another, in which case the creation of an effective world political organization for the human race which will respect human liberty, and afford a reasonable measure of national independence, but none the less impose limitations on both, becomes a prime necessity for the ultimate success of meetings such as the Pugwash Conference

Nor am I prepared to accept as presenting a stark and permanent dilemma the apparent antagonism presented by the alternative systems of socialism and free enterprise Both systems derive their principal economic and political ideas from traditions and writers whose point of view and even whose technical language largely antedate Darwin, and whatever of permanent value there may be in either, the greater part of the human race is at present living in conditions to which neither is self-evidently completely relevant

However this may be, I do not regard either the West or Communism as having reached a state of perfection which entitles either to adopt a purely negative, patronizing or destructive attitude towards the other The mere pressure on both of problems like population and food production will cause each to modify his practice, and, one hopes, not too long afterwards, to alter his political theories In the meantime aggressive or even moral talk unaccompanied by achievement in elevating the national and moral condition of mankind is a barrier to further progress which ought to be based on the interchange of technical, cultural and moral ideas by discussion, and on co-operation on objectives which can offer advantages to each What the world wants at the present time is less political polemics but deeper study and insight, more co-operation and more discussion, and greater concentration on practical and technical problems

The need for a central political authority, of which I have spoken, seems to me to be emphasized by two practical considerations The first is the nature of the nuclear weapon, and the second the magnitude and nature of the claim on resources likely to be made if human life outside the highly industrialized nations (or even including them) is to be substantially improved at an acceptable rate

Apart from pressing issues of testing, verification, and inspection which I do not propose to discuss, the core of the problem of nuclear weapons lies in the fact that they are not very secret, not very difficult to make, and that if nuclear energy for peaceful purposes is developed to anything like the extent we expect and hope, the quantity of plutonium (quite apart from enriched uranium) which will be available in the world will be substantial and widely diffused The so-called problem of the *n*th power will, therefore, always be with us whether or no the large powers conclude an effective disarmament agreement If, therefore, such an agreement is to achieve its purpose, it is plain that some international mechanism armed with effective powers must be created to contain this threat

The second argument which I use is related to the undoubted need of the so-called under-developed countries for aid I have made no attempt to calculate what this need amounts to since it is pretty obvious to anyone with even a nodding acquaintance with the communities and nations concerned that they could absorb without difficulty all the capital resources now being spent on armaments and a great deal more without their needs being met At present there seems to me to be neither rhyme nor reason for much that is being done, and I personally have no doubt that much of the resources at present being devoted by East and West to the provision of aid is either wasted, or even, as in the case of the provision of modern armaments, actually detrimental

Yet the dilemma presented is a genuine one New nations prize their independence more than any other asset It follows that it is difficult to assume any other means for identifying projects worthy of priority than the wishes of the Governments concerned—which are quite frankly not always very sensible—and there are perhaps few methods open to a developing country to secure favourable treatment other than a rather squalid attempt to offer, in return for aid, some degree of qualified political support, or the reverse, in the struggles for superiority between East and West

The need for an objective organization with adequate resources capable of selecting types of projects suitable for assistance, with a due regard to priority, and administering them without being drawn into the major ideological struggle would seem to be overwhelming in the interest of East and West alike and, if the proper means were discovered of carrying it out, a fertile field for co-operation would have been opened for cultivation

There is also clearly an established opportunity for international co-operation in the purely scientific field By 'international co-operation' I do not necessarily mean world co-operation in every part of the field, because I myself envisage much more complex and sophisticated patterns on which different groups of nations of different sizes and requirements co-operate for different purposes related to their special needs and responsibilities Still less by 'co-operation' do I necessarily mean 'centralization', for my own experience has led me to believe that certain types of international scientific co-operation can be achieved between nations supporting national programmes of scientific education and research of individual excellence

But I would identify the following fields in which international co-operation on some scale and with some kind of organization is becoming a practical necessity

The first of these in the field of the earth sciences—such as oceanography, geography, the study of the Earth itself, its mantle, its core, its magnetic field, the ionized belts beyond its atmosphere and so on, where quite apart from the expense involved the observations necessarily presuppose a world-wide chain of observers and observations Clearly, optical and radio astronomy are cognate fields in which parallel considerations apply

The second is where the mere cost of the apparatus necessary to carry out first-class research is such and its life as a research tool so short-lived that it is beyond the power of any nation and perhaps of any single group of nations to provide a complete range of the facilities required I would myself list here high-energy physics, nuclear physics, and, almost certainly, space research But as each science and discipline develops there are probably many other fields in which the same conditions will develop

The third is the whole range of studies connected with health Experience with the U K Medical Research Council has convinced me that in all the more radical aspects of medical research a single nation with, *ex hypothesi*, a limited geographical habitat is often too small a unit of study for positive results It is not simply that certain diseases are prone to attack all humanity wherever they live but also that new light on general problems can often be known only by study of local peculiarities I cite only the effect on the study of human genetics of the discovery of the relationship between sickle cell anæmia and resistance to malaria, or how the very suggestive facts recently come to light about the geographical distribution of a rare form of infantile cancer may throw a light on the general nature of cancer itself

But, of course, the whole problem of international co-operation comes to a head again on the subject of aid, with which I have already dealt in a slightly different connexion. For the greater part, human immunity to disease and want does not require any great advance in scientific knowledge so much as the application of known techniques and adequate resources, such as water, transport, fertilizers, power, engineering and building construction of all kinds I have already indicated that I do not myself believe that the use of aid by the two Power Blocs as a means of pursuing the ideological struggle is not really in the interests of either, or of the recipients of the aid I therefore identify as my last and most significant field for international technological co-operation the application of known technology for the development of human happiness and culture throughout the planet by means which will not by themselves secure to any Power Bloc a political advantage over the other

HAZARDS OF THE ROAD

By DAVID NAPLEY

Chairman of the Executive Council of the British Academy of Forensic Sciences

THE third annual scientific meeting of the British Academy of Forensic Sciences, held at the Law Society's Hall during July 28–29, was called to consider "The Hazards of the Road", a subject to which, having regard to the increasing public danger deriving from motor traffic, the sciences appear to have devoted disproportionately little research Following the presidential address by Sir Thomas Lund, secretary of the Law Society (in which he outlined the results of a comparative study which he had conducted into the practice and value of expert testimony throughout the world, and the merits of a panel of experts available to assist the judges), the meeting considered its subject, under four main headings the driver, the pedestrian, the vehicle and the road No doubt remained at the conclusion that the fitness, ability and skill of the driver transcended in importance every other single factor

As Prof H J Eysenck, of the Institute of Psychiatry (University of London), in the opening session estimated, while 10 per cent of traffic accidents are caused by mechanical and technical faults, something like 90 per cent are due to human factors Research work (much of it carried out in Finland, Austria and the United States), he said, in the form of psychological tests on those involved in accidents, for comparison with the results of such tests on those not so involved, tended to show personality traits such as aggressiveness, carelessness, impulsiveness and the like which are not present to the same degree in those persons who have been free from accidents

While noting this fact, the Law Section of the Academy had already observed how relatively little attention is paid to the physical and mental fitness of a person to drive before he or she is issued with a driving licence That this should be so is, perhaps, conditioned by the climate of public opinion exemplified by a speaker from the floor, who claimed "that, the driving licence, being a fundamental human right, the State has no right to deprive a man of such a licence unless it is absolutely certain that he cannot drive" This view was at direct variance with that of the Law Section as later expressed by Dr Ian Milne, H M Coroner for the County of London, who declared that the holding of a licence to drive a motor-vehicle is not a right but a privilege, for which the citizen must accept the responsibility of satisfying the authorities of his fitness, both mental and physical, to control the vehicle To take only two examples of the inadequacies of the present system: a driving licence need not be completed in the handwriting of the applicant Yet, is it not a significant factor in determining the qualifications to drive that the applicant is quite illiterate ? While, as Dr Milne remarked, a test of literacy is, perhaps, not always a test of intelligence, it is some guide. It would certainly afford no defence to a charge of disregarding traffic signs, it may be added, that a defendant had been unable to read them In the second place, driving licences are now issued for three-yearly periods, if one accepts the premise that in general applicants for licences truthfully and accurately answer the limited questions required of them (and there is clearly a predisposition to answer the questions in such manner as is most likely to induce the granting of a licence) there is no protection for the road-using public should some physical or mental disability supervene between the issue of the licence and the renewal at the end of the three-year period

If then a case is made out for more rigid control in relation to the granting of licences, what are the limits within which this control should be exercised ? Accident proneness is a concept, continued Prof Eysenck, which has haunted psychology for a long time There is, he asserted, much truth in the proposition that while most people tend to be relatively accident-free the great majority of accidents happen to a rather small sample of the total population at risk, nor, it appeared, was advancing age a significant cause of accidents Reaction-time is by no means the potent factor in the causation of accidents which popular opinion appears to believe The evidence is fairly strong that simple reaction-times in most situations are useless in identifying accident-prone drivers Older people tend to make up for their longer reaction times by driving more slowly, and Dr K G Norman, of the London Passenger Transport Board, while questioning the existence of accident-proneness at all, added that although as a man grows older, into middle age or further, his reaction-time is slowed, his eyesight is not quite what it used to be and his hearing is impaired, he nevertheless becomes a better driver Conversely, people with very fast reaction-times may tend to run greater risks and rely too much on their quick reflexes

A further series of tests have revealed that over large groups of drivers the relationship between ability and accident proneness is quite small, ability apparently making no difference to driving safety once an intelligence-quotient level of eighty or thereabouts has been reached Below eighty, however, there is a steep rise in the number of accidents encountered, and it does not seem to matter much which test is used to establish the mental level From this fact Prof Eysenck deduced that considerable caution should be exercised in allowing the dullest 20 per cent of the population to drive vehicles at all Of still greater importance, in his view, were tests of personality traits This work tended to show that on the whole the more emotional, more neurotic person tends to over-act to stress, to decline in performance and to take longer to recover his previous level of performance There is thus good reason to suspect that emotional people are contributing more than their share to the group of accident-prone drivers To what extent, therefore, should factors of this nature be involved in determining a citizen's right to be granted a licence to drive a motor-vehicle?

The application of greater stringency in the testing of applicants for driving licences would not, as Dr Francis Camps, secretary-general of the Academy, pointed out, be directed primarily to laws excluding from the roads those who were suffering or had suffered bodily or mental disability On the contrary, there are among those at present excluded, or who in the popular conception ought to be excluded, a number who would, as a result of properly conducted tests and investigations, be found to be within the safety limits, and thus eligible for a licence The current application form reads "Do you suffer from epilepsy ?" For all practical purposes an affirmative answer to-day debars the applicant from receiving a driving licence In the opinion, however, of Sir Francis Walshe, who presided over the first scientific session of the meeting, based on his own experience over a great many years of epileptics, the number of accidents which is due to epileptic attacks at the wheel seem to be extraordinarily small He appeared to lean against the automatic deprivation of driving licences in respect of all epileptics, especially, as one example, those who throughout their lives had fits only during sleep While in the view of Dr Walter Somerville, coronary artery disease and all heart diseases carrying a risk of sudden loss of consciousness should disqualify persons from driving public-service vehicles, long-distance lorries and taxis, he did not consider it feasible to ban persons from driving who are subject to occasional anginal attacks or who have recovered from a coronary thrombosis In his opinion, the application form for a driving licence should screen out those who know they are subject to fainting attacks, especially those with Stokes-Adams attacks, fainting due to vaso-vagal attacks, aortic stenosis, sensitive carotid sinus and other disease The difficulty, in this connexion, which the Law Section of the British Academy of Forensic Sciences had endeavoured to anticipate, is to be found in the words "those who know they are subject to fainting attacks, etc " The procedure, it was believed, should be sufficiently comprehensive to include in addition, and so far as practicable, those who might be subject to fainting attacks but who, until subjected to some compulsory tests, were unaware of that fact The difficulties, however, of designing such tests were not to be underestimated There must, moreover, be considerable support for the view expressed by Prof A L Banks that it would be invidious to draw a distinction between those persons who drive public-service vehicles and the like and the ordinary individual If, due to physical or mental disabilities, a driver is a menace on the road it seems reasonable to remove him from the road whatever the type of vehicle he may drive and however often he performs that function

Between 1949 (when the Road Research Laboratory first prepared comprehensive records) and 1961, casualties to pedestrians have been increasing as traffic increased but not in direct proportion On the other hand, casualties to non-pedestrians, that is drivers, motor-cyclists, cyclists and passengers, have been increasing more or less in direct proportion to the amount of traffic Since the number of motor-vehicles coming on to our roads tends to increase rather than diminish, the time may well come when all persons requiring a licence to take a potentially lethal weapon on to the roads may be required to subject themselves as a preliminary to tests, although much research remains to be done in this field before such tests are brought within the orbit of practical reality For the present, Dr Milne, in presenting to the meeting the recommendations of the Academy in this regard, suggested that the application form should be so worded as to make the questions regarding health difficult for the applicant to lie about without sound medical knowledge It should then be possible to divide the applicants into three classes those who were fit to drive on the face of their answers, those who were unfit to drive, and those who should be further assessed. The applicant would be expected to provide evidence from his own medical advisers, if such existed, and, additionally or in substitution therefore, would be required to attend before a duly constituted medical tribunal Dr Milne submitted to the meeting a suggested form of application, of which limited space prevents reproduction here but which will be published in *Medicine, Science and the Law*, the official journal of the Academy

If the emphasis in the granting of driving licences is to be moved from one of right to one of mere privilege should there not, as a corollary, be a substantial increase in the responsibility resting on Government authorities, both central and local, to ensure the maximum degree of safety in the construction of our roads, and on vehicle manufacturers in the construction of the vehicles? In a lively and informative contribution to the meeting, Mr J J Leeming, the county surveyor for Dorset, disputed the proposition that no matter what problems the road conditions may present to the driver it remains his responsibility to ensure his ability to solve them or take the consequences In reporting the results of his investigations he asserted that dressing curves on which the surface had polish, and applying no other treatment than the dressing, caused accidents to fall by 88 per cent It was, he said, his experience that it is not the places which look dangerous which have the accidents If the danger is obvious the motorist will take care, it is when the danger is hidden that he will fall into the trap He instanced an actual case in which two men having had enough, though not too much, to drink, disregarded a halt sign and drove into the intersection of cross-roads where they came into collision with a lorry and were killed It could be said that this was an accident caused by taking drink, but in fact a great number of other people who had taken no drink had done exactly the same thing at exactly the same cross-roads Following the death of these two men a roundabout was built at the cross-roads in question, since when there has been no accidents for two years despite a very heavy accident record theretofore

Dr John Bull, of the Road Injuries Research Group, Birmingham Accident Hospital, stressed the importance of accident design in the diminution of the number of road accidents He included within the term 'design' such terms as improved tyres, high hysteresis rubber for tyre construction and automatic releases from locking of wheels so as to continue control during skidding He also underlined the dangers to pedestrians of such things as car fins put on as a styling feature, mascots and projecting parts in general

Would the public interest be better served were a statutory obligation placed on both road authorities and manufacturers of motor-vehicles so that a claim to damages might lie, where an accident could be shown to have occurred due to some feature of the road or the vehicle which, while not such as might fairly be described as a defect in construction of the road or the vehicle, was nevertheless a contributing cause in the ultimate damage or injury which reasonable foresight, applied against the background of the facts and technical knowledge, might have avoided? Thus, where a collision occurs at the intersection of cross-roads, which, it may be reasonably inferred, would have been avoided had the appropriate authorities inserted a roundabout within the intersection, is it just that the responsibility to pay damages for the collision should fall solely on the motorists to the exclusion of the highway authority? Again, should not the manufacturers be held responsible, if not wholly at least in part, for damage resulting from injuries caused or aggravated by the presence of unnecessary or dangerously positioned bars, handles and ornamental gadgets?

It is in regard to the ascertainment of the causes of accidents, the causes of death and the placing of responsibility both criminally and civilly that the forensic sciences have their greatest application to the subject of the symposium One questions, however, whether the contribution which the law can make towards ameliorating the hazards of the road is likely to prove decisive Certainly there is room for new thinking about the subject Should there not be more prosecutions for bad driving rather than limiting the prosecutions, as tends to be the case to-day, to those instances in which an accident involving injury or damage follows? In cross-road collisions one party is seldom wholly to blame, should the police continue to choose one of two drivers and prosecute him to the exclusion of the other? Should not both parties be brought before the court, and their relative responsibility assessed and suitably punished? Too many defendants, particularly in cross-road collisions, leave the court believing that, while they may have been wrong they were not wholly wrong, and that it is unjust that the other party to the collision should have suffered no penalty whatsoever Ought not some clearer distinction be drawn between those persons who are guilty of dangerous or reckless driving, those who are guilty of careless driving and those whose driving, while falling short of deliberate recklessness or carelessness, involves a reduction in the standards of driving required to ensure public safety? At present a person driving dangerously, but whose offence has been committed without deliberation on his part, is, since a specific intent is not a necessary ingredient of dangerous driving, convicted of the same offence as the man who wantonly or recklessly drives his motor-vehicle in a dangerous manner Should not a new offence be created of driving a motor-vehicle in a manner inconsistent with the safety of the public and the offences of dangerous or reckless driving amended so as to require proof of a deliberate intention to drive in a dangerous or reckless fashion?

The last two sessions of the proceedings at which questions of this nature were canvassed were each held under the chairmanship of a High Court judge, namely, Sir Frederick Lawton and Sir Roger Omerod. The range of the discussions was extensive and was designed to illuminate the current methods and procedure for investigating the causes and responsibility for road accidents. These discussions will be fully reported, as will the remainder of the proceedings, in *Medicine, Science and the Law*.

If, at the conclusion of the meeting, one was left with the impression that more questions had been raised than problems solved, this served only to underline how much remains to be done in the field of road-accident research. That stimulus was given to such research there can be no doubt, and there may still be many, both within as well as outside the ranks of the forensic sciences, who may yet have cause to thank those participating in this scientific meeting for the knowledge which was imparted, the thought that was provoked, and the lives and freedom from injury which such greater knowledge will have preserved.

SATELLITE OBSERVATIONS OF THE ENERGETIC PARTICLE FLUX PRODUCED BY THE HIGH-ALTITUDE NUCLEAR EXPLOSION OF JULY 9, 1962

By A. C. DURNEY, PROF. H. ELLIOT, DR. R. J. HYNDS and DR. J. J. QUENBY
Imperial College of Science and Technology, London

THIS is a short account of some results obtained from a preliminary analysis of data on the energetic particle flux produced above the atmosphere by the recent high-altitude nuclear explosion in the vicinity of Johnston Island (latitude 16.7° N., longitude 169.5° W.). According to press reports, this explosion occurred at 0900h 15s U.T. on July 9, 1962, at an altitude of about 320 km and was in the megaton range. These results were obtained by means of a Geiger counter carried in the joint U.S./U.K. satellite *Ariel*. *Ariel* was launched from Cape Canaveral on April 26, 1962, into an orbit with inclination 54°. On July 9, 1962, apogee was 1,209 km and perigee 393 km. The Geiger counter is an Anton 302 which, together with a heavy-particle Čerenkov detector, makes up the cosmic ray package in this satellite. The counter is shielded by approximately 2 gm/cm^2 of assorted material, including 1 mm of lead, and responds by direct penetration to protons with energy $\geqslant 43$ MeV and to electrons with energy $\geqslant 4.7$ MeV. It also responds with an efficiency $\ll 1$ to γ-rays and to bremsstrahlung from electrons below the penetration energy. For technical reasons the circuitry associated with the counter was designed so that it would not record counting-rates in excess of ~ 45 counts/sec.

Information is available in the literature[1] on the results of three high-altitude explosions carried out in 1958 under the code name of 'Project Argus'. On the basis of these results it was to be expected that the July 9 explosion would result in the trapping in the geomagnetic field of energetic electrons from fission products together with protons and electrons from neutron decay, and that this trapped particle flux would probably still be detectable after a period of months. This expectation has been borne out.

Fig. 1 is a chronological plot of the intensity recorded by the Geiger counter for the period 0800 U.T.—2200 U.T. on July 9, 1962. (The apparent Geiger counter-rate is plotted. For rates above 300 there is an appreciable correction for the counter deadtime.) Points of special interest have been numbered and these numbers are used in the discussion in the text and in Fig. 2. This latter figure shows the track of the satellite for the same period as Fig. 1. Apogee occurs at a latitude of about 7° N. between longitudes 94° E. and 58° W. for the period under consideration, while perigee occurs near latitude 6° S. at longitudes between 96° W. and 108° E. The positions of apogee and perigee and north and south apices are indicated in Fig. 1. It can be seen from Fig. 1 that up to 0900 U.T. the Geiger counter shows the normal latitude effect for cosmic rays as *Ariel* moves from its northern apex down past the equator to its southern apex. The small peak (1) corresponds to passage through the lower edge of the inner radiation belt. At 0900h 15s U.T. (the time of the explosion) *Ariel* was at an altitude of 819 km in position latitude 52° S. and longitude 163° E., at a distance of 7400 km from Johnston Island. An initial burst of particles (2), which saturated the counter, occurred within 20 ± 10 sec of the explosion and lasted for 2 min. Three different explanations could be advanced for this prompt burst of particles: (i) they are β-particles from the decay of fission products, (ii) they are electrons resulting from neutron decay, (iii) they are outer radiation belt electrons the mirror point distribution of which is perturbed by the hydromagnetic disturbance resulting from the explosion.

Explanation (i) requires that the heavy fission fragments should be situated close to the magnetic line of force passing through the satellite at this time. Simple calculation shows that the minimum distance the fission fragments would have had to travel in the maximum permissible time of 30 sec is about 5,600 km, and this leads to velocities of 180 km/sec for the fission products. Such velocities are improbably high and therefore make this explanation correspondingly unlikely. Furthermore, the fission fragments would have to be neutral in order to move freely through the geomagnetic field. Explanation (ii) has also to be rejected because the flux of neutrons required appears to be higher than that which could be supplied by the explosion, which is assumed to produce a total of $\sim 10^{26}$ neutrons. We therefore believe that (iii) is the most likely explanation, that is to say, a magnetic field disturbance propagated outwards from the site of the explosion, with a velocity of the order 10^7 cm/sec, leads to a breakdown

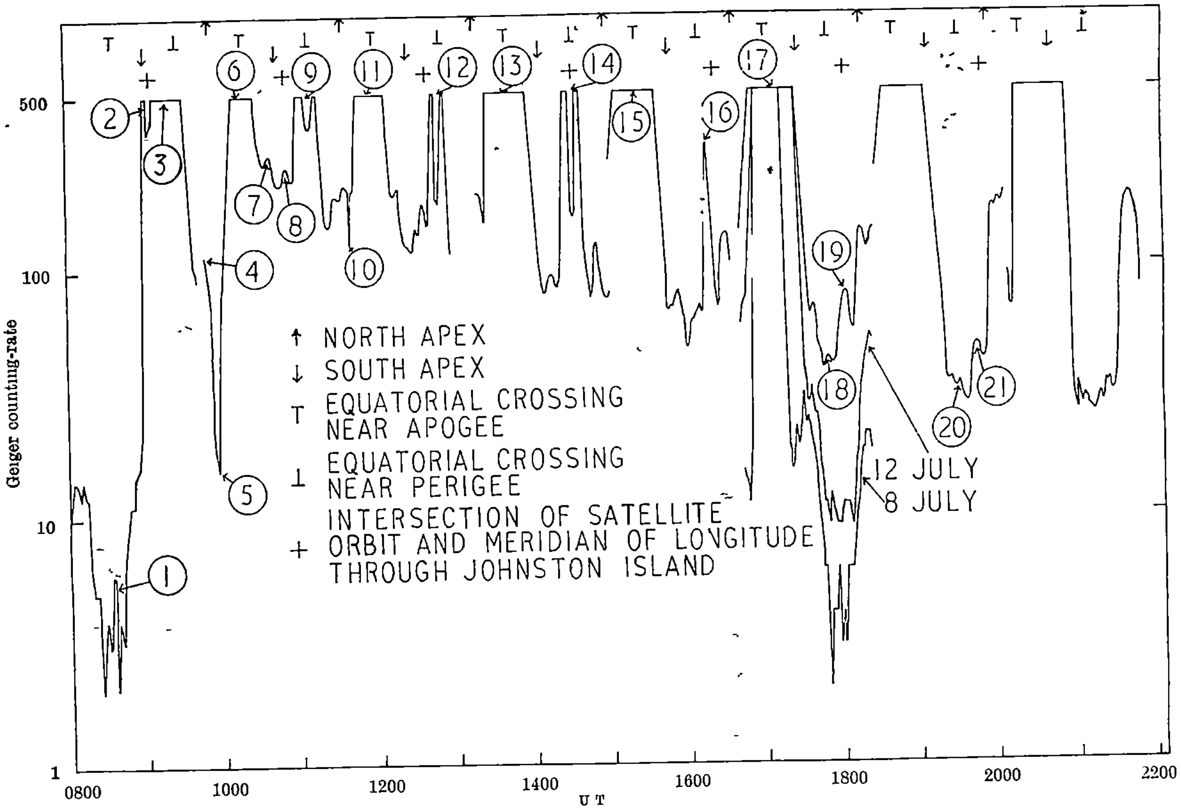

Fig. 1. Plot of *Ariel* Geiger counter-rate against time on July 9, 1962. The Geiger-rate is scaled by 8 and is taken over an interval of 92 sec. Corresponding data are shown for one orbit on July 8 and July 12, 1962

of the Alfvén adiabatic invariant of motion of the trapped particles and to a lowering of their mirror points with a consequent increase in intensity at the altitude of the satellite.

At 0908 U.T. the counter again saturates (3) as the satellite encounters a high flux of fission product β-particles drifting eastwards over the Pacific from the site of the explosion. As the satellite crosses the north Atlantic the intensity falls again, but at (4) it is still much above the pre-explosion background, indicating that there are additional trapped particles on the magnetic field lines which intersect the satellite at this time. These field lines go out as far as 4 Earth radii in the equatorial plane. The magnetic line of force passing through the point of explosion, on the other hand, attains a maximum altitude of ~800 km in the equatorial plane, and the radius of curvature of the β-particle trajectories being not more than a few kilometres, we would expect them to be rather closely confined to the magnetic shell containing this line of force. It is not immediately obvious, therefore, how the electrons find their way on to magnetic shells extending as far away as 4 Earth radii. There would appear to be two possibilities: either the electrons are neutron decay electrons, or else they are neutral fission fragments endowed with sufficient kinetic energy to enable them to travel on ballistic trajectories and so reach the appropriate lines of force, where they decay. In order to do this they do not, of course, need to reach heights of 4 Earth radii. It is sufficient that their trajectories carry them to high latitudes. At the present time we are unable to distinguish with certainty between these two possibilities, but the former is perhaps the more likely.

Returning to Fig. 1, it is seen that a minimum value (5), corresponding to normal pre-explosion intensity, is reached at 0956h. The eastward drift velocity for electrons with energy ≥4.7 MeV is such that electrons injected into the geomagnetic field at sufficient height to clear the atmosphere will occupy a shell completely encircling the Earth in a time of the order 20 min. Thus this shell will be complete before 0956, and it is necessary, therefore, to account for the apparent gap observed at this time and position. It can be shown that this gap arises because of the geomagnetic anomaly in the South Atlantic. These particles which we might expect to be observed by *Ariel* when it is in this position have their conjugate mirror points below sea-level in the South Atlantic, and have therefore already been absorbed west of the satellite's magnetic meridian. Thus, in a sense the satellite is at this time in the shadow of the geomagnetic anomaly and cannot observe the shell of additional electrons. When the satellite is in a corresponding position on its next orbit, a similar but much smaller dip in intensity (10) occurs at 1138h 30s. On this occasion, however, the intensity does not fall to the level prevailing prior to the explosion, as it did on the previous orbit. This behaviour appears to be consistent with the change in mirror point altitudes to be expected from the rather different magnetic field strength at the appropriate conjugate points.

After passing through this position of minimum intensity (5) the counting-rate rises again to saturation-level (6) as the satellite nears apogee in the equatorial region. In this position it is sufficiently far into the natural inner radiation belt for saturation to occur even in the absence of additional particles

Course of Theoretical Physics — Volume 2

The Classical Theory of Fields

Revised Second Edition

L. D. LANDAU and E. M. LIFSHITZ, *U S S R Academy of Sciences*

A valuable and unique addition to the literature of theoretical physics This revised second edition gives a completely up-to-date presentation of the theory of electromagnetic and gravitational fields

"The clarity of style, the conciseness of treatment, and the originality and variety of illustrative problems make this a book which can be highly recommended". *The Physical Society*

"This is an excellent and readable volume" *Science*

410 pages Numerous Illustrations 80*s* net

The Application of Organic Bases in Analytical Chemistry

E. A. OSTROUMOV, *U S S R Academy of Sciences*

A collection of systematic studies by the author, on the applications of a particular class of organic compounds—organic bases—in the analytical chemistry of inorganic substances Since the Russians have a large background knowledge to call upon in the methods of analysis involving precipitation by pyridine, this book will be of the utmost interest to all specialists in the field

CHAPTER HEADINGS The precipitation of metals using pyridine , The precipitation of metals by pyridine in the presence of its salts , The precipitation of metals with hydrogen sulphide in the presence of pyridine , The precipitation of metals using α-picoline , The precipitation of metals with hydrogen sulphide in the presence of hexamethylenetetramine , Methods for the separation of metals using pyridine α-picoline and hexamethylenetetramine

180 pages 50*s* net

Foundations of the Galois Theory

M. M. POSTNIKOV, *The Mathematical Institute of the Academy of Science of the U S S R*

A lucid and concise description of the Galois theory of equations and its application to the question of the solvability of equations by radicals This book covers the basic definitions of group theory and leads the reader to the proof of the unsolvability by radicals of the general equation of degree $n \geqslant 5$

CONTENTS THE ELEMENTS OF GALOIS THEORY The elements of field theory Necessary facts from the theory of groups Galois theory

THE SOLUTION OF EQUATIONS BY RADICALS Additional facts from the general theory of groups Equations solvable by radicals The construction of equations solvable by radicals The unsolvability by radicals of the general equation of degree $n \geqslant 5$

115 pages 42*s*. net

PERGAMON PRESS

HEADINGTON HILL HALL OXFORD

Out of Print Soviet Scientific, Technical and Medical Books and Serials

Do you have difficulty in obtaining Soviet Publications?

Do they quickly become out of Print?

There is a solution!

Soviet libraries receive books from the publishing houses of the USSR. which they exchange for foreign publications, and I R Maxwell & Co Ltd is able to obtain a regular flow of these publications, on order only, from several famous Soviet libraries.

The Maxwell organization is recognized by librarians and book-buyers the world over as the leading and most reliable University and Industrial booksellers It offers you and your library a unique and comprehensive service for publications from all countries

ATLAS OF ANALYSIS LINES

by Halina Jaffe

assisted by N. Turkeltaub

An ability to identify spectrum lines quickly is among the first needs of the spectrochemical analyst Halina Jaffe's atlas derives from a new and simple concept and is unique in depicting but a single spectrum—the arc spectrum of pure iron—in considerable enlargement and as a photographic negative Its purpose is to facilitate identification of the analysis lines of sixty-nine other elements, the positions of which are marked above and below the spectrum The atlas is divided into three parts

Details on application

Price 10 guineas individual parts, 25 guineas complete

SPECTROCHEMICAL ABSTRACTS

VOL. VII, 1956–1959

by E. H. S. van Someren
and F. Lachman

The scope of this well-established series has been widened to include X-ray fluorescence spectroscopy

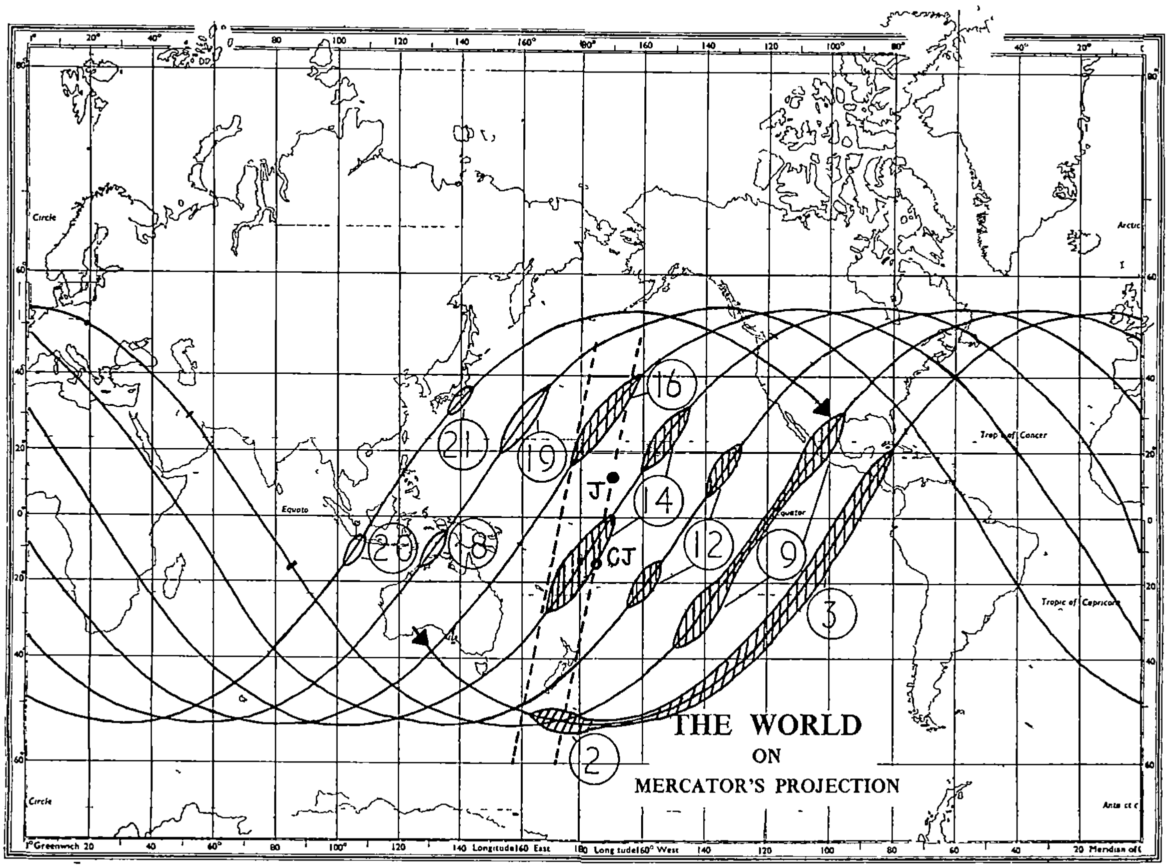

Fig 2 Geographical position of the low-altitude Johnston Island shell on July 9, 1962 Shaded areas indicate positions where the Geiger counter was near saturation Unshaded areas indicate relatively small intensity peaks Numbered positions are referred to in the text Position of Johnston Island (*J*) and its magnetic conjugate (*C J*) are indicated together with the magnetic meridian through Johnston Island (broken line)

from the explosion The Geiger counter, therefore, gives us no information about the additional particle flux in this region However, the behaviour of the Čerenkov counter reveals the presence of a high intensity of additional particles in this region

The twin peaks (7) and (8) correspond to the motion of the satellite, at high southerly latitudes, across the magnetic lines of force connecting with the heart of the outer radiation belt, indicating that the trapped particle intensity is greatly enhanced out to at least 5 or 6 Earth radii

The twin intensity peaks (9) occur on three successive equatorial crossings, and their geographical positions are shown approximately in Fig 2 These peaks correspond to the passage of the satellite through the magnetic shell containing the point of explosion over Johnston Island, and indicate the presence of fission product electrons drifting eastward on the surface of this shell From the distribution of geomagnetic field strength we know that particles on this shell must plunge into the atmosphere either over, or just to the east of, the South American sub-continent Consequently, this shell cannot extend completely around the Earth and the lifetime of particles on it is therefore only a matter of minutes A vestige of this particle shell can still be detected the following day, and in order to account for this we must conclude that it has been continuously fed by the decay of fission products remaining in the neighbourhood of the line of force connecting Johnston Island and its conjugate point It would seem likely that these fission products were charged and trapped in the magnetic field. The drift velocity for heavy ions of this kind is very low and is in a westerly direction, so that the western edge of the electron shell would be expected to creep westward only very slowly That there is a rather clearly defined western boundary to this shell can be seen from Fig 2 The regions of enhanced intensity to the west of Johnston Island, which are shown without hatching, represent much lower peak intensities than those to east of the magnetic meridian shown by the dotted line

Returning to Fig 1 once more, (15) represents the passage of the satellite through the inner radiation belt at apogee, while the peak labelled (16) lies in the western edge of the low-altitude Pacific shell which stretches from the longitude of Johnston Island to the Atlantic, and (17) is the inner radiation belt again For this particular orbit directly comparable data are shown for July 8, 1962, the day preceding the explosion, and also for July 12, 1962 Comparison of these three traces gives some indication of the rate of decay of the additional trapped electrons resulting from the explosion In this connexion it should be emphasized that the decay is not exponential, and consequently it is not possible to predict the probable life-time of the trapped particles A non-exponential decay is to be expected since the life-time of the trapped electrons observed at any particular point is a function of energy and pitch angle

For particles trapped in the geomagnetic field, the intensity at any point on a particular magnetic shell should depend only on the scalar magnitude of the

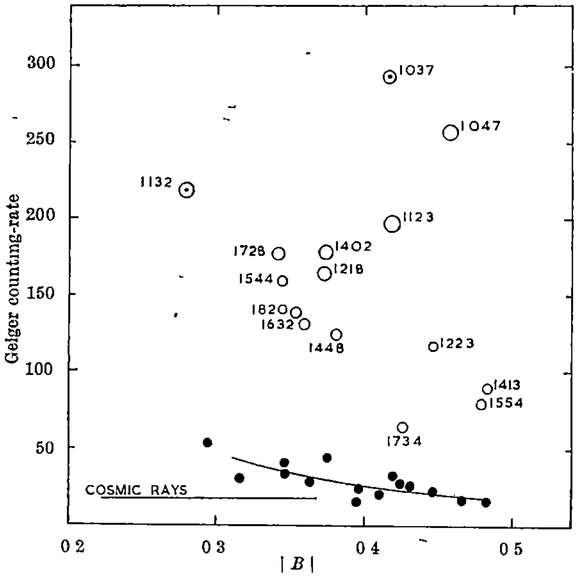

Fig 3 Plot of Geiger counter-rate against scalar magnitude of the magnetic field in gauss, | B |, for the magnetic shell intersecting the geomagnetic equatorial plane at 3 87 Earth radii O, July 9, 1962, observations, ●, April 30, 1962, observations Observation times are given in U T next to the July 9 points The Geiger-rate is scaled by 8 and is taken over a 92-sec interval

field at that point Fig 3 shows the distribution of intensity as a function of field strength on the magnetic shell which intersects the equatorial plane at approximately 3 9 Earth radii The open circles represent the counting-rates on July 9, 1962, and the black circles the corresponding rates for April 30, 1962 The background cosmic-ray rate is also shown It will be seen that for all times on July 9, 1962, the particle intensity is above normal, as represented by the April 30, 1962, data, and that it varies monotonically with $|B|$, indicating that we are observing genuinely trapped particles at this time The points at 10 37, 10 47, and 11 23 lie above the curve and probably contain a contribution from short-lived particles which disappear within 2 5 h of the explosion

This account is based on an analysis of only a part of the total data available, but, in view of current interest in the geophysical phenomena associated with this event, it seemed worth while to produce a preliminary report even though some of the interpretation is rather tentative Continued examination of these artificially trapped electrons during the next year or so will provide information on the trapping times for particles in the radiation belt This information is crucial in understanding the origin of the trapped radiation, but unfortunately it is unlikely to be forthcoming from *Ariel*, which has operated only intermittently since July 13, 1962, as a result of deterioration of the solar cells presumed to be due to the effects of this additional radiation—a result which was not foreseen

Our conclusions may be summarized as follows

(1) There is evidence for the redistribution of the mirror points of the naturally occurring electrons in the outer radiation belt This redistribution was probably the result of a hydromagnetic disturbance propagated outwards from the site of the explosion

(2) Following the explosion, an additional population of electrons remained trapped in the geomagnetic field These electrons occupied the region of the natural radiation belts out to a distance of at least 5 or 6 Earth radii and at large distances were most likely the product of neutron decay

(3) A low-altitude shell of fission product decay electrons was formed over the Pacific Ocean, stretching westward from Johnston Island to the neighbourhood of the Atlantic coast of the American continent This shell lasted for more than a day and was continually supplied with electrons by the decay of charged fission fragments supported in the Earth's magnetic field in the neighbourhood of Johnston Island

(4) A considerable part of the additional radiation had disappeared by July 12, 1962, as shown in Fig 1, but the decay is not exponential and consequently the life-time of the trapped radiation cannot be predicted until the decay law is established

We are indebted to the N A S A for making this joint U S /U K project possible, and to all those members of the N A S A team who were concerned in the preparation and launching of *Ariel* We wish particularly to thank the two project managers, Mr R C Baumann and Mr M O Robins

CONVECTION CURRENTS IN THE EARTH'S MANTLE

By Prof S K RUNCORN

King's College, Newcastle upon Tyne, and Jet Propulsion Laboratory,
California Institute of Technology, Pasadena, California

In a recent attempt to provide an explanation of continental drift[1], I postulated that convection currents were occurring in the Earth's mantle This supposes the mantle to have zero strength under stresses persisting over millions of years and to have a Newtonian viscosity I then applied Chandrasekhar's[2] theory of convection in spherical shells under a radial gravitational field, in which he showed that instability in the marginal state occurs through a convection pattern described by a spherical harmonic, the degree of which depends on the ratio (η) of the radii of the inner to the outer spherical boundaries Vening Meinesz[3] had argued that spherical harmonic analysis of the present topography of the globe reflects the convection pattern in the Earth's mantle, as the continents would tend to lie above the descending currents He showed that the present positions of continents and oceans implied that the convection currents in the mantle had strong harmonics of third, fourth, and fifth degree Chandrasekhar's calculation showed that, as η for the Earth's mantle is at present 0 55, these harmonics are those through which the thermally induced instability would be expected to occur

Therefore, I argued that if the accretion theory of the origin of the Earth was accepted and it was supposed that the Earth's iron core had only separated gradually through the Earth's life, as originally suggested by Urey[4], and its radius was still increasing, a change in the number of convection cells in the mantle might recently have occurred. This increase in the degree of the convection was taken to be the mechanism for the dispersal of the continents since the Palæozoic. Thus the surprisingly recent time—compared with the life of the Earth—at which continental drift, as understood by geologists and palæomagnetic workers, occurred is given a rational explanation.

It has recently been possible to obtain new evidence for this process. The ratio η of core radius to the Earth's radius, at which the Rayleigh number of a given harmonic becomes less than that of the harmonic of next lower degree and therefore may be expected to develop in place of the latter, can be calculated from Chandrasekhar's theory; but the values depend on the boundary conditions used. It is clear that for the Earth these are a free inner boundary and a rigid outer one, for shearing stresses at the core-mantle boundary must vanish and there can be no doubt of the strength of the rigid crust of the Earth. If these boundary conditions are used one can derive[5], from Chandrasekhar's work, that the ratio of the radii of core to Earth at which the second harmonic replaces the first harmonic as the mode through which instability occurs is 0·06; for the transition from second to third the value of η is 0·36; and for third to fourth 0·49. During these transitions the continents will be under considerable stress as the convection-pattern changes to its new form. The last such transition from fourth harmonic to the fifth is observed in the geological column as continental drift.

The question now arises whether there is any record in the Earth's crust of the earlier transitions; these mode changes would be expected to cause world-wide orogeny, involving extensive recrystallization of crustal material. Radioactive age determinations have been made on igneous and metamorphic rocks which have been formed in the deeper parts of the crust as the result of orogenic forces. It is therefore of great interest that the ages obtained for such rocks have been found to be grouped in peaks of about ± 100 m.y. around the dates 200 my., 1,000 m.y., 1,800 m.y., and 2,600 m.y. ago. The most recent peak covers much of the geological record since the middle Palæozoic, and we have seen that this is associated with continental drift and the transition from a fourth to fifth degree convection pattern in the mantle. It is natural to identify the 1,000-m.y. peak with the transition of the third to fourth degree convection pattern, the 1,800-m.y. peak with the transition from the second to third degree, and the 2,600-m.y. peak with the transition from the first to second. Gastil[6] has reviewed the radioactive age dates and has shown that the peaks are present whether the ages are determined by the rubidium–strontium method, the lead method, or the potassium–argon method. American rocks give a peak at 1,300 m.y., which is thought to result from later metamorphism. He also shows that in spite of the poor coverage in some continents, the peaks appear to represent world-wide events. Davis and Tilton[7] had also come to a similar conclusion concerning the reality of these events: they are not simply due to deficiencies of sampling. It must, however, be emphasized that the peaks are broad (of the order of 200 m.y.) and further proofs that they are truly world-wide are much needed[8].

In this way the dates at which the core attained these critical values is determined as shown in Fig. 1. Before this new information was available, I had assumed that the core started its growth 4,600 m.y. ago—at the time of the Earth's origin[1]. Fig. 1 shows that it must have started its growth a little over 3,000 m.y. ago. But this, of course, is in fact entirely reasonable: one must allow time for the Earth to heat up to temperatures at which the creep processes necessary for convection will become important. As these depend on a factor exp (E/kT), where E is an activation energy, k Boltzmann's constant, and T the temperature, it may be supposed that the creep process rather suddenly became important and then convection commenced. The source of the heat is the uniform distribution of radioactivity. Thereafter, it may be supposed that the convection just carries off the heat generated by radioactivity within the Earth and by the release of potential energy due to the settling of iron into the core.

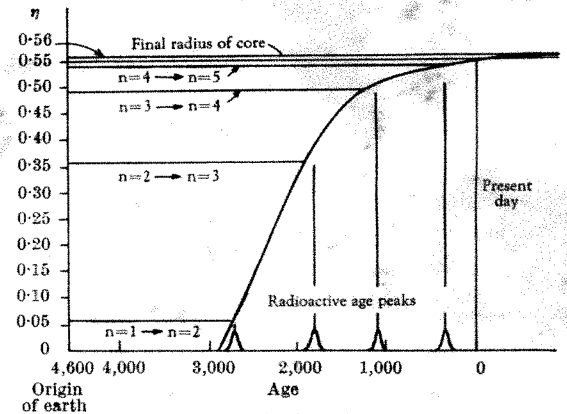

Fig. 1. Growth of radius of Earth's core

The law of growth of the core found by the above argument fits well with the simple model suggested previously by me[1], that is, that the rate of movement of iron into the core is proportional to the surface area of the core and to the mass of iron remaining in the mantle. Initially, the radius will grow linearly with time as equal increases in radius represent increments of mass proportional to the surface area of the core. Eventually, the curve will become asymptotic to the final radius (g) of the core when all the iron has left the mantle. It is therefore worth fitting by least squares the theoretical equation previously derived on this basis[1] :

$$\log_e \frac{(r/g-1)}{(r/g)^2+(r/g)+1} + 2\sqrt{3}\,\tan^{-1}(-2\,r/g-1)/\sqrt{3} = Kt + c$$

where K and c are constants and r the radius of the core at time t. The fitted curve is shown in Fig. 1. The value of g is found to be 0·56: thus about 6 per cent of the free iron still remains in the mantle.

A NEW SEISMIC RESEARCH GROUP FOR EDINBURGH

By P. L. WILLMORE
Royal Observatory, Edinburgh

THE formation of the Seismic Research Group in Edinburgh is a symptom of a deep-seated revolution in seismology—occasioned fundamentally by the impact of electronics on an old-established science. The developing pressures have been noticeable for the last decade; but their growth had been delayed, more than in most sciences, by the sensitivity, economy and reliability of the traditional electromagnetic seismographs. The photographic-drum seismogram produced by these instruments is so compact and inexpensive, and it contains so much information, that it still remains the best type of record for certain purposes. However, the data content is not readily convertible into a form suitable for electronic manipulation, and this fact is now imposing grave limitations on the utilization of such records.

A less-fundamental but more-potent demand for technical advance arose from the recognition that seismic observations offered the best prospects for the detection of underground nuclear explosions. The inadequacies of seismological technique began to emerge at the Geneva Conference of Experts in 1958, when the first proposals for a world-wide detection system were drawn up, and were further demonstrated when the analysis of underground tests in the United States in the autumn of 1958 revealed a number of unsatisfactory features in the proposed detection system.

The American reaction to this situation was to set up the Panel on Seismic Improvement which, in 1959, produced its report entitled "The Need for Fundamental Research in Seismology". Acting on the conclusions of this report, the United States expanded its already substantial effort by an order of magnitude, and now has a research programme which is prodigious by the standards of a decade ago.

In Britain, expansion had to start at a much lower level, because very little effort had been going into observational seismology beforehand. However, the Atomic Energy Authority set up a vigorous research group under the leadership of Dr. H. I. S. Thirlaway, the Meteorological Office established its Gassiot Fellowship as a step in the expansion of its own

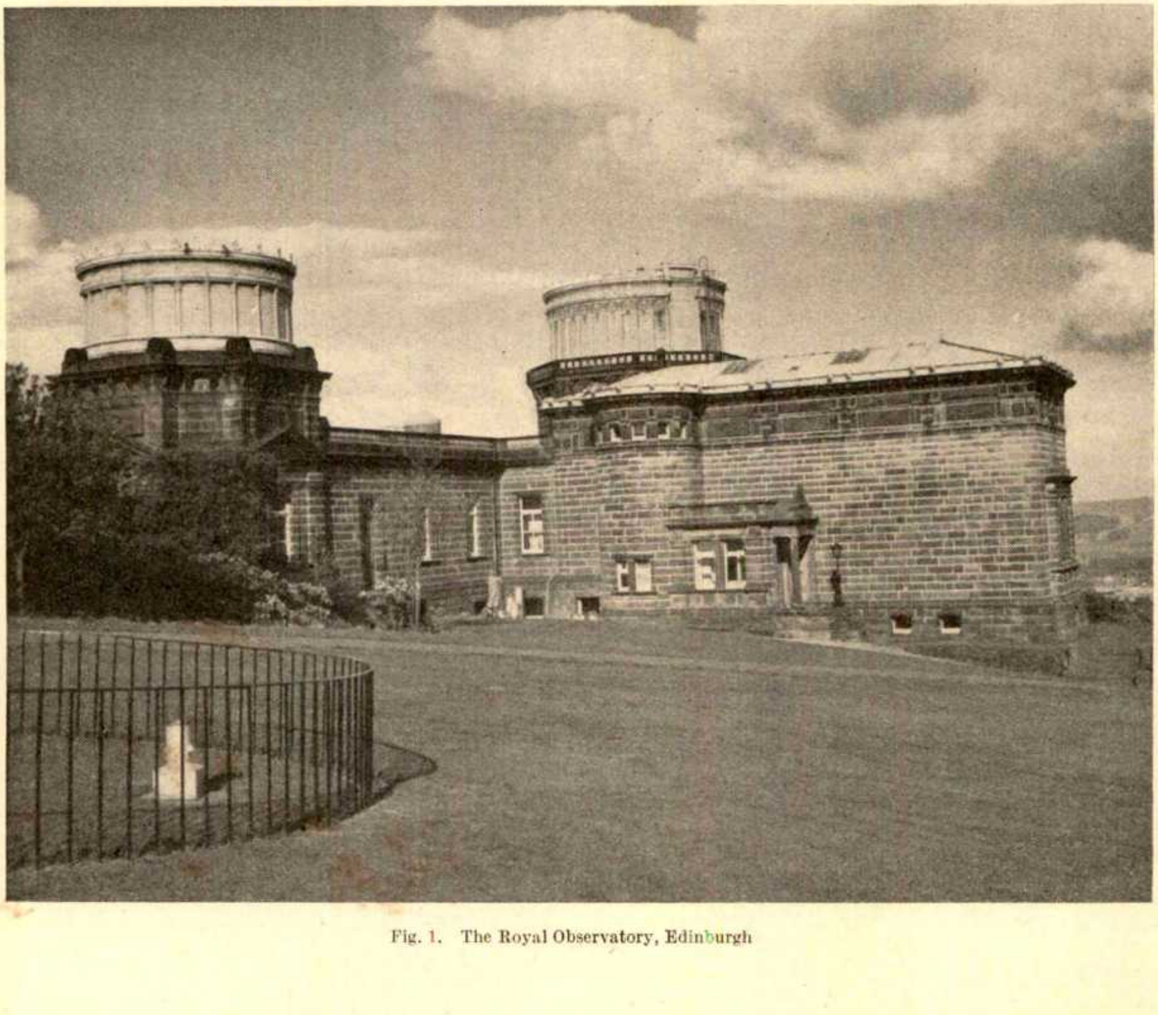

Fig. 1. The Royal Observatory, Edinburgh

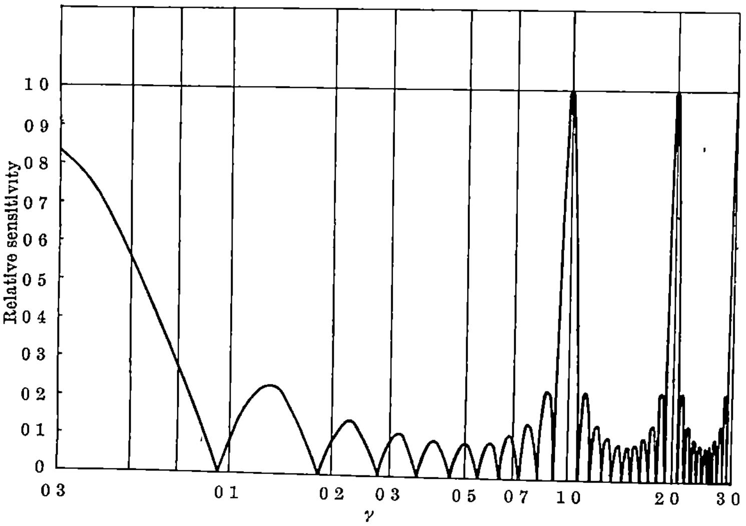

Fig 2 Output of a linear array γ is a parameter which depends on the velocity and frequency of the incoming wave (*By courtesy of the Atomic Energy Authority*)

effort in seismology, and the Advisory Council on Scientific Policy recommended that two university research groups should be set up These groups were to be at Cambridge and Edinburgh respectively

At the beginning, it was expected that the Edinburgh group would be a small one, but as plans advanced and field tests by the Atomic Energy Authority became available, the advantages of Scotland as a recording base began to emerge A modern seismograph can detect the vibration of a car moving a mile away, or of a train at 5–10 miles By such standards the whole of south-east England is intolerably noisy, and even secluded rural sites experience something like 100 times the amplitudes of high-frequency vibration which can be found in parts of Scotland The difference in noise-level does not apply to the movements of about 5-sec period which are generated by waves in the oceans, but probably reappears for periods of the order of minutes, which correspond to the tilts generated by the movement of heavy vehicles

As a consequence of the difference of noise-level, it was decided that the major recording centres of the Atomic Energy Authority and of the Meteorological Office should both be set up in the vicinity of Eskdalemuir, in the Southern Uplands of Scotland At this stage, the other advantages of Edinburgh as a centre of training and research came to be more fully appreciated and plans for development there were enlarged accordingly The seismic project is being housed in the Royal Observatory (Fig 1), which is related to the University through the fact that its director, the Astronomer Royal for Scotland, is also the University's professor of astronomy The numerous facilities available on the Observatory side include mechanical and electronics workshops, a library and a time service, and the support of senior research staff who are already applying advanced techniques in the fields of electronic instrumentation and data processing The University provides the academic opportunities with which it is hoped to attract students and research fellows to the project

The staff of the Seismic Group at present includes the senior seismologist, two experimental officers

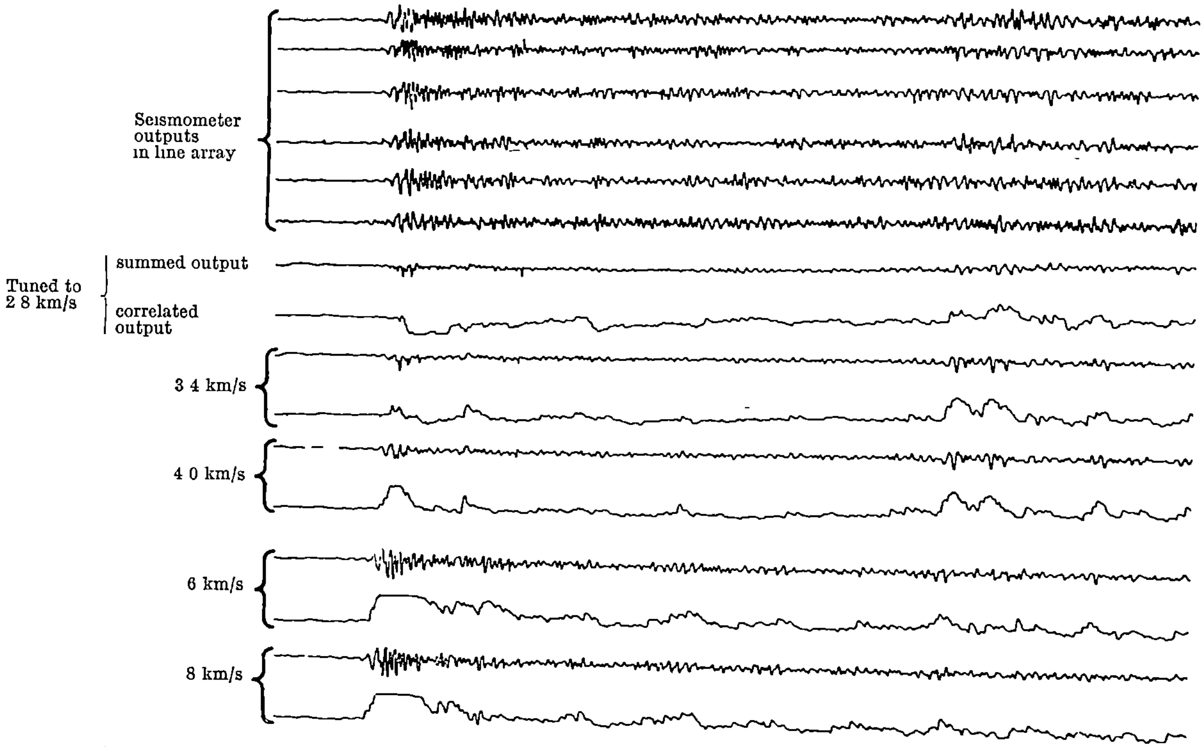

Fig 3 Outputs from six channels of an array, with phased sum and cross-correlator output for an explosion seismogram (*By courtesy of the Atomic Energy Authority*)

and a Department of Scientific and Industrial Research Fellow, who between them are responsible for field-work, fixed-station recording and data processing. The most urgent outstanding staff requirement is to strengthen the group on the theoretical side, and a second research fellowship is available for this purpose.

The first objective of the Research Group will be to exploit the possibilities of large seismic arrays for teleseismic studies. Several of these (including one at Eskdalemuir) are in service or under construction by the Atomic Energy Authority, each consisting of two lines of seismometers, 10 km or more in length, and having 11 seismometers in each line. The individual outputs are recorded side by side on magnetic tape.

The Authority analyses the data in a way which has been highly developed in radio astronomy, but which is comparatively new to seismology. First, the outputs from each line are added together, phase delays being introduced such that outputs corresponding to a set of waves travelling across the array in a given velocity and direction are added in phase, whereas the outputs from other types of event are distributed in time. As a result of this procedure, the ratio of the signal to the noise which is uncorrelated from one element to another is reduced in proportion to the square root of the number of elements. Disturbances which propagate coherently across the array, but at a velocity different from that which has been set up for playback, may be rejected more or less strongly than this (Fig. 2).

Next the summed outputs from the two lines are multiplied together, and the product smoothed so as to yield the cross-correlation of the two sets of data. As a result, signal components common to both lines are squared in the output, and therefore smooth to a positive value. Other signals, and random noise, yield products of fluctuating sign, the effects of which are reduced by the smoothing process. The results of this procedure are illustrated in Fig. 3, which shows a few of the outputs from one line of a cross, together with summed and correlated outputs for various lags. The correlator peaks for S waves are clearly visible in the velocity range of 3.4–4 km/sec, even though these waves are hard to see on the individual channels. The P-wave correlation at 6–8 km/sec saturates the playback system.

In addition to its preparations for utilizing data from the Atomic Energy Authority arrays, the Edinburgh Research Group is building up a set of portable seismographs capable of detecting earth movements in the range of periods from 0.1 to 100 sec. The outputs will be recorded on magnetic tape, in a form similar to that used in the fixed arrays. When the equipment becomes operational, it should be possible to set it up either for conventional studies of explosions and local earthquakes, or as an array for the study of teleseisms. In the latter case, the use of self-contained field stations removes the limitations on the scale of the array, and hence on the range of wave-lengths which can be handled. On the other hand, it will not generally be possible to lay out a set of detectors in exact conformity with an optimum geometrical pattern, and we shall also lose the convenience of having the outputs recorded side by side on a single tape. The theoretical and instrumental problems which arise from this situation will provide a challenging field of investigation.

The third problem of interest to the group is to improve the performance of detecting elements, for it is clear that progress in many fields of seismology has been limited by the lack of records having adequate band-width and dynamic range, adequate freedom from cross-coupling and the effects of parasitic oscillations, and adequate long-term stability. During the past two years seismometers have been much improved, and in Great Britain we now have two types in production, having periods adjustable up to 3 sec and 20 sec respectively. In each of these the minimum frequencies of parasitic oscillations have been pushed up to more than 100 c.p.s., and excellent temperature stability has been achieved. With the aid of appropriate electronic circuitry, there is now a good prospect of recording up to the limit of Earth noise, for all periods up to and including that of the fundamental period of the Earth's free oscillations.

The final problem of data acquisition is to set up the instruments in the right places. Although Scotland is the most favourable part of the United Kingdom for this purpose, there will be many types of problem for which it is not the best place in the world. For this reason we feel that our emphasis on mobility offers advantages over any approach which relies solely on the output of fixed stations.

OBITUARIES

Prof. R. Ruggles Gates, F.R.S.

REGINALD RUGGLES GATES, professor emeritus in the University of London, who died in London on August 12 at the age of eighty, held the chair of botany at King's College from 1921 until 1942. During this period, the Department grew considerably and attracted many research students, especially from overseas. He was made a Fellow of the Royal Society in 1931 and of King's College, London. He was a supporter and at various times an officer of many societies, especially the Eugenics Society, the Royal Anthropological Institute, the Linnean Society and the Royal Microscopical Society, of which he was an honorary member.

Gates was born on May 1, 1882, in Middletown, Nova Scotia, and educated at Mt. Alison University, McGill University and the University of Chicago. He also worked at the Woods Hole Marine Biological Station and at the Missouri Botanical Gardens. In London, he was lecturer in biology at St. Thomas's Hospital for two years from 1912, also lecturing on cytology at Bedford College and on heredity in relation to cytology at Oxford. During 1915–16 he was associate professor of zoology in the University of California, during 1917–18 he was instructor in aerial gunnery to the Royal Air Force.

Gates had wide scientific interests, and he was a prolific writer. Much of his botanical work was descriptive, dealing with the cytology of various plants and with the microspecies of *Œnothera* (evening primrose). The latter interest grew out of his early work on the mutants of *Œnothera lamarckiana*, discovered by Hugo de Vries, of whom he was an enthusiastic adherent. This led to his first book, *The Mutation Factor in Evolution*, published in 1915 He had strong and lasting views on the significance of mutations, not least those of large effect, in evolution, a view expressed in his *Mutations and Evolution* (1921)

The most important early work of Gates was the discovery (independently made by Miss Lutz) that the *gigas* mutant was tetraploid, with twice the chromosome number of the normal species He also found triploid and trisomic mutants and the dominant *rubricalyx*, but the tetraploid was of especial interest since it had arisen directly from the normal diploid, differed from it in certain small characters and was isolated from it reproductively, hybrids between diploid and tetraploid being infertile This first discovered instance of autotetraploidy was a great stimulus to further research His later work was on the evolution of the wild species of *Œnothera*, differing from one another only slightly, true breeding but easily crossed artificially, and perhaps rather impermanent in nature In it he came to accept the views of Renner, Darlington and Cleland, though grudgingly and preserving some of his own earlier misconceptions The disagreements which were involved at least served to stimulate useful research

Early in his scientific life, Gates developed a keen interest in human genetics and evolution and anthropology His books, *Heredity and Eugenics* (1923) and *Heredity in Man* (1929), were good introductions to their subjects and undoubtedly stimulated many people to gain an interest Later, he published an immense two-volume compilation, *Human Genetics* (1946), followed by *Human Ancestry* (1947) and *Pedigrees of Negro Families* (1949) He was particularly interested in primitive peoples, collecting data on blood groups and other characteristics, more recently he investigated the genetics of skin pigmentation in negroids

Gates was an inveterate traveller, whether collecting *Œnothera* species in North America or traversing Africa in the pursuit of anthropological data Travelling, indeed, was his sole recreation and one he never relinquished, in his seventies he visited Cuba, Mexico, Japan, Africa, Australia and India in furtherance of his studies of primitive peoples *A Botanist in the Amazon Valley* (1927) records observations which were often recounted to appreciative undergraduate classes

In outlook, Gates was primarily an observer, describer and systematist He made experiments rather blindly, for he had little capacity for conceiving scientific hypotheses and for devising experimental tests His early work, which was his best, was observational He had a strong faith in what the microscope would reveal to his eye, scorning theoretical principles which controverted these observed 'facts' His research students were closely supervised and expected daily to demonstrate a good cytological preparation, they were well trained in microscopical techniques, though conservatively

As a colleague he was difficult to get to know at all intimately, for he seemed unable to relax and be at ease Though generally mild-mannered, he could be most stubborn and would rarely admit to an error or retract a view previously expressed Through scientific controversy, not always on the right side, and his abundant writings, he certainly stimulated scientific thought and research

His first wife was the late Dr Marie Stopes, the well-known botanist and pioneer advocate of birth control and sex education, this marriage was annulled In 1930 he married Miss Jenny Williams, the singer, and in 1955 he married Mrs Laura Greer (*née* Nowotny) of Texas

D G CATCHESIDE

Prof. F. P. Dwyer

PROF F P DWYER, head of the Biological Inorganic Chemistry Unit in the Australian National University, died suddenly at his home in Canberra on June 22, from a coronary occlusion, at the age of fifty-one years

Prof Dwyer was born at Nelson Plains, New South Wales, and was educated at the Marist Brothers' College, Maitland, and the University of Sydney, where he graduated in 1932 From 1934 until 1945 he was senior lecturer and head of the Inorganic Chemistry Department at the Sydney Technical College, and during 1945–46 he was senior lecturer in inorganic chemistry in the University of Sydney He was a visiting professor at Northwestern University during 1953–54, and in 1956 he was appointed to a new chair in inorganic chemistry in Pennsylvania State University, but he resigned from this appointment in 1957 without taking up the post to become reader and head of the Biological Inorganic Chemistry Unit in the John Curtin School of Medical Research of the Australian National University For his outstanding contribution to inorganic chemistry he was elected, in 1960, to one of the first personal professorships created in the Australian National University

The versatility of Prof Dwyer and the breadth of his interests in research are shown by more than 150 publications spread over the following topics X-ray analysis, micro-analytical reagents and procedures, isomerism of the triazines and diazoamino compounds and their metal derivatives, the chemistry of platinum, palladium, rhodium, iridium, ruthenium and osmium, the redox potentials of simple compounds and complexes of the platinum metals, the optical activity and kinetics of racemization and substitution of Group 8 metal complexes, the diastereoisomeric effect and the principle of configurational activity, the stereochemistry of multidentate chelates, electron transfer reactions, the effects of metal complexes in biological systems and stereospecific influences in octahedral complexes

For his work on diazoamino compounds, their metallic salts and metallic hydroxide lakes, he was awarded the degree of D Sc of the University of Sydney, the Royal Australian Chemical Institute's Rennie Medal (1940) and the Smith Medal (1945) In 1953 he was awarded the University of Melbourne's David Syme Medal and Prize for distinguished work in natural science

In later years, as his international reputation grew, he held the George Fisher Baker non-resident lectureship in Cornell University (1954) and the first Chemical Society lectureship instituted by the Chemical Society of London for the purpose of encouraging the study of chemistry in Australian universities Shortly before he died he had given a series of lectures at the invitation of the American Chemical Society. He is survived by his widow, two sons and a daughter.

Prof Dwyer's colleagues will remember him for his outstanding ability, his personal charm, friendliness and modesty His students will remember not only these qualities, but also his unfailing cheerfulness, sense of humour, encouragement and enthusiasm in the face of their many problems and errors Scientifically, he is a great loss and he leaves many sad friends

A SARGESON

NEWS and VIEWS

Oceanographical Branch, Hydrographic Department, Admiralty:

Commander F W Hunt, M.B.E

COMMANDER F W HUNT, lately superintendent of the Oceanographical Branch of the Admiralty under the Hydrographer, has been appointed in command of H M Surveying Ship *Cook* operating in the Western Pacific Commander Hunt received his initial training in the *Conway*, entering the Royal Navy in 1939, and specializing in hydrographic surveying in 1942 He was appointed a member of the Order of the British Empire in 1945 for his hydrographic surveying work in connexion with the opening up of the ports in the Adriatic during the advance of the Eighth Army Since the War he has served in a succession of surveying ships on most stations including the R R S *John Biscoe* in the Falkland Islands Dependencies In 1955 he assumed command of the East Coast of England Survey and during 1957–60 served as hydrographer of the Royal New Zealand Navy, being the last Royal Navy officer to hold this post

Commander J Paton

COMMANDER J PATON has been appointed to succeed Commander F W Hunt as superintendent of the Oceanographical Branch of the Admiralty Commander Paton specialized in hydrographic survey work in 1947, after serving as a junior officer in the fleet for five years Since then he has served at sea in surveying ships at home and when abroad, mainly in Pacific Ocean waters For the past sixteen months he has been in command of H M S *Cook*, working in the Fiji Islands and Gilbert and Ellice Islands, and during this period undertook deep-sea surveys in connexion with the laying of the Pacific section of the projected Commonwealth cable

The Royal Armament Research and Development Establishment, Fort Halstead :

Dr D. H Black, C M G

DR D H BLACK is retiring from the directorship of the Royal Armament Research and Development Establishment, Fort Halstead, Kent He was born in New Zealand in 1899 and received his early education there, obtaining first-class honours in physics at Canterbury, and then went to work under Lord Rutherford in the Cavendish Laboratory, Cambridge, in 1923, gaining his Ph D in 1925 He spent some fourteen years in industrial research with Standard Telephones and Cables, ultimately as head of the Valve Laboratory, before joining the Government service in September 1939 when he was appointed superintendent of the then Air Defence Experimental Establishment In 1943 he was seconded to the Admiralty for special liaison developments for radar and communications He returned in 1945 as superintendent in charge of research at the now re-named Radar Research and Development Establishment, and in 1947 he moved to Ministry of Supply Headquarters, becoming director of electronics research and development in 1949 In 1953, Dr Black was appointed head of the U K Ministry of Supply mission in Australia During his three years in this post, the interests of the Ministry in Australia expanded considerably with the development of the Guided Weapon and Atomic trials at Woomera and Maralinga For his work in this post Dr Black was appointed C M G On returning to England in 1956, Dr Black was appointed director-general of electronics research and development at the Ministry of Supply Headquarters He assumed the appointment of the then Armaments Research and Development Establishment in 1958

Mr E. W Chivers

MR E W CHIVERS has been appointed to succeed Dr Black Mr Chivers, who has been principal superintendent of the Electronics Division of the R A R D E , graduated in physics (special) with honours in 1927 at Queen Mary College, London After a short period of postgraduate research he entered Government service in 1928 and went to the Research Department, Woolwich, where he was engaged on acoustical research in connexion with sound ranging In 1951 he was transferred to the Searchlight Department at the Air Defence Experimental Establishment, Biggin Hill His work there was concerned with physical problems associated with searchlights and their use, later extending to problems of searchlight design and automatic control In 1940 he was transferred with the remainder of the Biggin Hill establishment to Christchurch to join the Army Radar Group which had been transferred from Bawdsey There he became leader of the team responsible for the application of radar to the control of searchlights, the introduction of which into the Services made such a great improvement in searchlight operation He continued in radar work when the Establishment (by this time the Radar Research and Development Establishment) was transferred to Malvern and was concerned with a number of Army radar projects throughout the War In 1953, when the Radar Research and Development Establishment and the Telecommunications Research Establishment were combined as the Radar Research Establishment, he was promoted to deputy chief scientific officer and became head of the division responsible for ground radar for both the Army and the Royal Air Force In 1954, he was appointed director of atomic weapons (Development and Production) at the Ministry of Supply Headquarters

Mathematics at Dublin: Prof H Halberstam

PROF HEINI HALBERSTAM, who succeeds the late T S Broderick as Erasmus Smith professor of mathematics in the University of Dublin, is one of the group of distinguished mathematicians who were students at University College, London, immediately after the end of the Second World War He was on the mathematical staff of the University of Exeter from 1949 until 1957, with leave of absence to spend most of the session 1955–6 as a visiting lecturer at Brown University, Providence, R I, and the rest as a visiting lecturer at the University of California, Berkeley California Since 1957, Halberstam has been reader in mathematics at Royal Holloway College in the University of London He has been playing an increasingly prominent part in all aspects of the mathematical life of the University, where his presence will be sadly missed. As organizer of the seventh British Mathematical Colloquium in Exeter in 1955, and as a vigorous secretary of the London Mathematical Society since 1959, he has played a much appreciated part in the mathematical life of the whole country In 1961, for example, he undertook the organization of the London Mathematical Society's highly successful first 'instructional course' on functional analysis Halberstam is well known for his work in the theory of numbers, particularly on statistical properties of arithmetic functions and on various topics in additive number theory Apart from some present work connected with finite fields, he is collaborating with Prof K F Roth on a book about general arithmetic sequences In Royal Holloway College he has stimulated much work by colleagues and research students, he can be expected to build up a notable school in Dublin

The Grassland Research Institute

THE annual report for 1960–61 of the Grassland Research Institute, Hurley (7*s* 6*d*), records results of research on a wide field of scientific and practical interests The work is essentially concerned with the grass crop, and the broad object is to determine the right food for cattle and sheep and the type of sward which will most benefit the underlying soil The Department of Herbage Agronomy has continued the intensive study of introduced grasses and pure swards have been established to follow seasonal growth and reaction to management Further work has been concerned with methods of incorporating autumn- and winter-growing grasses into seed mixtures New chemical herbicides have made possible complete sward replacement by the combination of sprays, re-seeding and top dressing all done as one sequential operation without the plough or cultivator Investigations have been initiated in the Plant Physiology Department to elucidate the relative importance of leaf area and carbohydrate reserve on re-growth of pastures following defoliation It was found that some ecotypes of tall fescue from North Africa made better growth during winter at Hurley compared with indigenous grasses, and growth analysis revealed that this was in part due to a greater leaf-area ratio and in part to greater photosynthetic efficiency Preliminary results from a study on flowering of white clover indicated that low temperatures induced flowering which was augmented by long days although low temperature was not essential for flowering

Among the various experiments carried out by the Ley Agronomy Department may be mentioned the attempt to grow wheat after killing leys with herbicides and without disturbing the soil deeper than required to sow the seed In general, grain yield was the same from ploughed land as from the herbicide treatment Results from the Department of Microbiology suggest that there is a correlation between soil fertility and certain soil micro-organisms but absolute proof is lacking Ryegrass and cocksfoot have been successfully cultivated in an atmosphere of carbon dioxide labelled with carbon-14 to obtain uniformly labelled material for decomposition experiments on the soil Digestibility trials with six grasses were performed by the Department of Biochemistry and Animal Nutrition which confirmed that herbage digestibility depended both on species and stage of growth A new method for analysis of organic acids in silage was developed The Grass/Animal Ecology Department analysed the grazing system in so far as it affects milk supply, lambing percentage, stocking-rate and season, all of which influence the growth-rate of lambs The Animal Agronomy Department has been concerned with assessment of animal production (beef cattle and sheep) under different management conditions and on differing sward types

The Society for Folk Life Studies

THE second annual conference of the Society for Folk Life Studies was held in the University of Reading during September 7–9 It was attended by seventy people from all parts of the British Isles as well as overseas The meeting began with a lecture on "The Study of Folk Life from a Swedish Standpoint" by Prof Sigurd Erixon of Stockholm, one of the world's foremost authorities on folk-life studies The remainder of the conference was devoted to a consideration of folk-life studies in relation to other disciplines, and among the speakers were Dr R B Wood-Jones of the University of Manchester, the well-known architectural historian, Mr Basil Megaw, director of the School of Scottish Studies, University of Edinburgh, Dr Ronald Buchanan, a geographer from the Queen's University of Belfast, and Mr David Murison, editor of the *Scottish National Dictionary* In addition there was an excursion to the Cotswolds, where the domestic architecture of that region was studied, while the University of Reading provided a reception for delegates at its Museum of English Rural Life

The first volume of *Folk Life*, the Society's new journal, should be ready early in 1963 It will be a well-illustrated publication of some two hundred pages, edited by Stewart Sanderson of the University of Leeds The next conference of the Society (1963) will be held in the University of Leeds Membership of the Society is open to all those interested in the traditional life of Great Britain and Ireland, and the annual subscription is two guineas Members will receive *Folk Life* free of charge and they will be able to attend all the meetings organized by the Society Further information can be obtained from the secretary, J G Jenkins, Welsh Folk Museum, St Fagans, nr Cardiff

Index Biologicus

FOR many years biologists have felt the need of at least as comprehensive a cover of their literature as has been achieved in chemistry and physics With the setting up of the Department of Scientific and Industrial Research Library at Boston Spa a realistic appraisal of the problem became possible The Council of Management of Biological and Medical Abstracts, Ltd , with encouragement from a number of British biological societies and financial support from the Pergamon Press, carried out in 1961 an investigation as to the size, nature and cost of an *Index Biologicus* It was found that the number of journals which would contain material of biological information, excepting purely applied material and clinical papers already covered in *Index Medicus* would exceed 5,500 and total no less than 200,000 titles per annum If these were classified in an author and subject index the total number of entries to give a reasonable coverage would be 1,000,000 and require at least 10,000 pages per annum Such a mass of material would have to be handled with the maximum of automation It was estimated that the time from the appearance of an article to its publication in the

Index Biologicus would take six weeks and the annual cost would be £72,000 The Council and its publisher are very conscious of the lack of such a rapid, but by no means ideal, collation of the biological literature, but feel that if the cost has to be borne entirely by the subscriber it would be uneconomic and regret their inability to undertake the publication of the *Index Biologicus*

Oak Ridge National Laboratory Publications

THE brochure, *ORNL*—3300 (Volume 1), consisting of special lists by title of publications, reports issued and papers delivered at scientific meetings which originated from Oak Ridge National Laboratory during 1961, covers biology, chemistry, mathematics, physics, metallurgy and instrumentation Articles for which reprints are obtainable on request are indicated by the letter *R* as part of the index number and in requesting reprints only the index number need be quoted Papers listed in the section "Reports Issued" are available for use at the Atomic Energy Commission Depository Libraries or copies may be purchased The brochure concludes with a list of nine theses and an author index

ABC of the Universe

A BOOKLET recently issued under this title by the British Broadcasting Corporation consists of a set of seven broadcast talks by well-known astronomers (Pp 39 London. British Broadcasting Corporation, 1962 2*s* 6*d*) The series is designed to present a view of how the universe appears in terms understandable by the layman To this end the publication appears most lucid and informative, and at the price it is one of the best in the whole field of popular astronomical literature Dr Lyttleton conducts us through the solar system while Dr Reddish examines the life, birth and death of a star This leads naturally to a discussion of the galaxy from the point of view of optical astronomy by Dr Willstrop and from the point of view of radioastronomy by Prof Hanbury Brown The observational approach to cosmology is discussed in the final three lectures by Dr Baldwin, Prof Ryle and Sir Bernard Lovell Dr Baldwin discusses the expansion of the universe while Prof Ryle discusses the limits which are imposed on our observing capabilities He points out why radioastronomy can take us further into space than optical astronomy Sir Bernard Lovell finally links the various theories about the universe with the present state of our knowledge and demonstrates the exciting possibilities of future researches The B B C has done astronomers a service by the publication of this well-balanced account of present-day views at such a modest price

The International Commission on Zoological Nomenclature

NOTICE is hereby given of the possible use by the International Commission on Zoological Nomenclature of its plenary powers in connexion with the following cases, full details of which will be found in *Bulletin of Zoological Nomenclature* (19, Part 5, published on September 10, 1962) (1) Validation of *Ictonyx* Kaup, 1835, and *striatus* (*Bradypus*) Perry, 1810 (Mammalia) *Z N* (*S*) 758 (2) Designation of a neotype for *Rana fasciata* Burchell, 1824 (Amphibia) *Z N* (*S*) 1253 (3) Validation of *elegans* (*Arizona*) Kennicott, 1859 (Reptilia) *Z N* (*S*) 1454 (4) Designation of a type-species for *Eucypris* Vávra, 1891 (Crustacea, Ostracoda) *Z N* (*S*) 1462 (5) Validation of *rostrata* (*Aelia*) Boheman, 1852 (Insecta, Hemiptera) *Z N* (*S*) 1490 (6) Validation of *Tetrastichus* Haliday, 1844 (Insecta, Hymenoptera) *Z N* (*S*) 1503 (7) Designation of a type-species for *Dicellomus* Hall, 1871 (Brachiopoda) *Z N* (*S*) 1504 (8) Validation of *Lingulops* Hall, 1872 (Brachiopoda) *Z N* (*S*) 1505 (9) Designation of a type-species for *Orbiculoidea* d'Orbigny, 1847 (Brachiopoda) *Z N* (*S*) 1506 (10) Suppression of *piperita* (*Cypraea*) Gray, 1825 (Gastropoda) *Z N* (*S*) 1510 (11) Validation of *Jovellania* Bayle, 1879 (Cephalopoda) *Z N* (*S*) 1511 (12) Suppression of three specific names of Spanish Palæozoic Crinoidea *Z N* (*S*) 1513 (13) Validation of *Vanikoro* Quoy & Gaimard, 1832 (Gastropoda) *Z N* (*S*) 1524 (14) Validation of Phasmidae (Insecta, Orthoptera) *Z N* (*S*) 1167 Any zoologist who wishes to comment on any of the above cases should do so in writing to the Secretary, International Commission on Zoological Nomenclature, c/o British Museum (Natural History), Cromwell Road London, S W 7, before March 10, 1963

Pest Control

SOME of the results of the work carried out by the Infestation Control Laboratory of the Ministry of Agriculture, Fisheries and Food are shown in a publication, the second of its kind, issued by the Ministry of Agriculture, Fisheries and Food (*Infestation Control a Service to Agriculture and Food Storage* H M S O 6*s* 6*d*) Outlined first is the scientific work done by the Ministry on the control of pests of stored products and harmful mammals and birds during a period of sixteen years up to 1958 The second part covers the subsequent period to 1961 Since 1958, additional facilities have been acquired by the Ministry to meet the growing need for work on the scientific aspects of the control of land pests and birds One of the most difficult and urgent problems being investigated is the large increase of the numbers of coypus in East Anglia Following a description of the organization of the Laboratory, the three main sections of the booklet, insect pests of stored products, rats, mice and coypus, and land pests and harmful birds, give useful information on the habits of the pests, together with the latest available information about their control

Birds in Suffolk

1961 was noteworthy in Suffolk for the addition of two new species to the county list (*Transactions of the Suffolk Naturalists Society*, 12, Part 2, 1962) In April, a Bonelli's warbler was trapped and ringed at Walberswick and, on September 1, a buff-breasted sandpiper was seen at Minsmere Although examples of this American wader had previously occurred on Breydon, they had all been claimed for Norfolk Thanks to the intensive watching that now takes place in all likely areas on the coast, as well as the increase in mist-netting and trapping, it will be surprising if one or more species that are new to Suffolk are not recorded annually for some time to come Rarities from Minsmere included a gull-billed tern in June, followed by a Caspian tern and three roseate terns in July and August, a long-tailed skua, icterine warbler and pectoral sandpiper in August, and a yellow-browed warbler in October The long-tailed skua, which was seen at close range, was the first known record for Britain during this century Minsmere was also visited, for the second winter running, by a kite Another, or more probably the same, bird was seen at Tunstall and Snape a fortnight later An immature purple heron was found injured beneath electric pylons at Herringfleet on September 9, and an ortolan, the first definite record for many years, was identified at Walberswick on September 1

Requirements for Poliomyelitis Vaccine

OVER the past four years, a number of World Health Organization Study Groups have met to consider requirements for biological substances which could be recommended for international adoption Recommended requirements for inactivated poliomyelitis vaccine were published three years ago, but, since that time, live poliomyelitis vaccine, administered orally, has come into use for mass immunization programmes in many countries It has therefore become necessary to formulate requirements for the oral vaccine The recommendations of a recent report are restricted to the preparation of oral poliomyelitis vaccine in monkey kidney cultures, since, so-far, only vaccines prepared by this method have been extensively used in man (*Technical Report Series* No 237 *Requirements for Biological Substances* 7. *Requirements for Poliomyelitis Vaccine* (*Oral*) Pp 29 Geneva World Health Organization, London H M S O, 1962 1 Swiss franc, 1*s* 9*d*, 0 30 dollars) In drafting the requirements, the Study Group took into consideration the regulations and requirements already proposed by a number of national authorities, as well as data submitted by experts in the field, including the authors of three oral vaccines which have been tested in large-scale immunization campaigns in man

Ramsay Memorial Fellowships

THE following Ramsay Memorial fellowships in chemistry for the year 1962–63 have been awarded A Canadian fellowship to Dr R C. Thompson, University of Manchester, an Indian Fellowship to Dr R S Thakur, University of Cambridge, a Netherlands Fellowship to Mr A Schuyff, Imperial College of Science and Technology, London, a New Zealand Fellowship to Mr D T Dixon, University of Reading, a Spanish Fellowship to Dr D Vazquez Martinez, University of Cambridge, a United States Fellowship to Mr Jack H Freed, University of Cambridge

The following fellowships have been renewed for the same year to Dr H Suginome (Japanese Fellowship), University of Cambridge, Mr B. A Grigor (New Zealand Fellowship), University of Leicester, Dr F Alonso Matthias (Spanish Fellowship), University of Cambridge

University News : London

PROF R A L BLACK, Chamber of Mines professor of mining engineering in the University of the Witwatersrand, has been appointed to the chair of mining at the Imperial College of Science and Technology as from October 1, 1963

Dr J F Kirkaldy, reader in geology at Queen Mary College, has been appointed to the chair of geology tenable at that College Dr R L Bell, lecturer in metallurgy in the Imperial College of Science and Technology, has been appointed to the readership in science of materials tenable at Queen Mary College Dr P M Cohn, lecturer in the University of Manchester, has been appointed to the readership in pure mathematics tenable at Queen Mary College

The following titles have been conferred *Professor*, on Dr A M Cook (pharmaceutics), in respect of his post at the School of Pharmacy, on Dr B Dawes (zoology-parasitology), in respect of his post at King's College *Reader*, on Mr B B. Boycott (zoology), in respect of his post at University College, on Dr R E Burge (biophysics), in respect of his post at King's College, on Mr W H Gosney (mechanical engineering), in respect of his post at King's College

Announcements

THE Medical Research Council Clinical Chemotherapy Research Unit at the Western Infirmary, Glasgow, has been reconstituted as the Atheroma Research Unit under the direction of Dr. B. Bronte-Stewart The Unit will be primarily concerned with research on occlusive vascular disease

A MEETING on "Scattering of Elastic Waves", arranged by the Materials and Testing Group of the Institute of Physics and the Physical Society, will be held on October 12 Further information can be obtained from the Institute of Physics and the Physical Society, 47 Belgrave Square, London, S W 1

THE annual Pittsburgh diffraction conference will be held at the Mellon Institute, Pittsburgh, during November 7–9 Subjects under discussion will include instrumentation and techniques, structures, metals and alloys, defect lattices and/or radiation damage, X-ray and electron diffraction microscopy Further information can be obtained from W H Robinson, Carnegie Institute of Technology, Pittsburgh 13, Pennsylvania

THE autumn meeting of the British Society for Parasitology will be held at the Zoological Society of London on October 19 Subjects under discussion will include biochemical techniques, ionizing radiations and radioisotopes, *in vitro* cultivation and serological techniques, electron microscopy Further information can be obtained from Dr L P Joyner. Central Veterinary Laboratory, Ministry of Agriculture, Fisheries and Food, New Haw, Weybridge Surrey

THE thirty-sixth annual conference of Aslib will be held in Blackpool during October 2–4 Subjects under discussion will include sharing skills, technical aid to developing countries, the foreign language barrier in science and technology, monitoring current technical information with the British technology index, linking research and design, relations between a central information unit and sectional units, a multi-purpose, computer-integrated system for centralized information dissemination, storage and retrieval Further information can be obtained from Aslib, 3 Belgrave Square, London, S W 1

A CONFERENCE on "The Epilepsies and Society", arranged by the Scottish Epilepsy Association, will be held at Dunblane Hydro during November 9–11 Subjects to be discussed will include the challenge of the epilepsies in the welfare state, the scope and limitations of present-day treatment of the epilepsies, the management of the epilepsies in Germany—vocational guidance, settlement in employment, problems within the family, the social integration of persons with epilepsy, the employment of persons with epilepsy Further information can be obtained from Mrs Christina G Kilgour, Scottish Epilepsy Association, 24 St Vincent Place, Glasgow, C 1

THE NUFFIELD FOUNDATION

THE seventeenth annual report of the Nuffield Foundation, covering the year ended March 31, 1962*, records allocations during the year totalling £1,823,996, of which £26,600 was for biological research and £219,150 for other scientific research. Repayable grants totalling £43,850 included interest-free loans of up to £25,000 repayable within 10 years to the University of Glasgow for rebuilding the freshwater biology research station on Loch Lomond and of up to £25,000 for 5 years to the Society for the Promotion of Nature Reserves to establish a loan bank so that when a site or area of scientific interest comes on the market they can buy it without delay. The sites which this Society and the County Trusts have been able to acquire are becoming more and more valuable to scientists, and biological and physiographical work of outstanding importance, both amateur and professional, is being carried out in these reserves. A further, final grant of £7,500 over 3 years has been made to King's College, University of London, for Prof. J. F. Danielli's studies of the cell cortex, cell movement and transport. A two-year programme of research on the chemistry and biochemistry of pteridines at the Royal College of Science and Technology, Glasgow, is being supported with a grant of £3,850 over two years, while a special grant of £3,000 was made to Armagh Observatory to complete and furnish the library, in the expectation that future needs of the Observatory will be met by the Government of Northern Ireland. A grant of £10,000 was made to Birkbeck College, University of London, to cover installation and initial working of a computer for mechanical translating.

Grants totalling nearly £650,000 in medicine included £200,000 over 10 years to the Institute of Child Health to enable it to develop its department of growth and development to become the basic science of the department of pediatrics, on the understanding that at the end of 10 years it would have been absorbed into the University of London, and £55,000 over 5 years, also to the Institute of Child Health, to establish a Nuffield Neonatal Research Unit at the Hammersmith Hospital, £200,000 to the University of Edinburgh towards the establishment of a tissue and organ transplantation unit, to be called the Nuffield Unit for transplantation surgery, on the understanding that the Department of Health for Scotland will provide about £100,000 over 5 years, up to £25,000 over 5 years to the Unit of Biometry, University of Oxford, for a programme of operational research methods applied to the improvement of health services, £15,000 to the University of Birmingham to enable Prof. Ian Bush to build up his department of physiology and create a research group in chemical physiology, a concluding grant of £7,050 over 3 years to the University of Leeds for extension of the work in the Departments of Diagnostic Radiology and Medical Physics on developing techniques of X-ray image detection by television methods, and a grant of £50,000 to the British Medical Association towards the conversion of a wing for the library: the reconstructed library will be known as the Nuffield Library of the Association.

In social research and experiment a capital grant of £50,000 was provided for the National Institute for Social Work Training towards the cost of putting the buildings in good order, this, with the grant of £250,000 over 10 years previously promised, assures the Institute of continued existence for 10 years, within which period help is expected to be forthcoming from public funds and other sources. A grant of £22,500 was offered towards the cost of an inquiry being conducted by the University College of Swansea into the lower Swansea Valley as a basis for subsequent development. £56,000 over 4 years to the London School of Economics and Political Science and the School of Oriental and African Studies is for a scheme of field research in south-east Asia and the borderlands of southern China into modern social economic, political and cultural changes in the region, a third survey of London life and labour, to be conducted by the Centre for Urban Studies, University College, London, and the London School of Economics and Political Science is being supported by a grant of £30,000 over 3 years, and an investigation into the functions and development problems of town centres by King's College, Newcastle upon Tyne, by a grant of £10,500 over 3 years. Of special significance at the present moment is the grant of £23,000 over 2 years to Political and Economic Planning for a study of management attitudes in industry, and the ways in which these attitudes may retard growth of the economy and the development of the export trade.

Among grants for the Commonwealth Overseas, besides those for the newly independent territories, those of up to £13,000 for 3 years on a tapering basis to the Government Central Pedagogical Institute, Allahabad, in support of a diploma course in teaching English (on condition that the Government took over the full cost at the end of the period) and of £3,200 to the Universities of New South Wales and Sydney for a joint research project into crystal-structure analysis using X-ray data from a rotating-anode source at low temperature may be mentioned. No change is reported in the types of awards in medicine and dentistry, but a considerable extension of the programme for scholarships in tropical medicine is to take effect in 1962–63. One medical research fellowship, three medical fellowships, three fellowships and three assistant fellowships, three Heinz fellowships, one dental research fellowship, two dental fellowships and two dental scholarships were awarded. There was an unusually promising group of applicants for biological scholarships and bursaries and one scholarship and four bursaries were awarded. Under the scheme for the Dominions and Colonies ten awards were made in medicine, 13 in the natural sciences (including one Indian fellowship in engineering), and 11 in the humanities and social sciences: there were also 10 Canadian travel grants. In addition to scholarships to three African farmers from the Federation of Rhodesia and Nyasaland, eight scholarships were awarded to farmers from Australia,

---

* The Nuffield Foundation. Seventeenth Report for the year ended 31 March, 1962. Pp. xiv+159. London: The Nuffield Foundation, 1962 (see also p. 1235 of this issue).

Canada, Rhodesia and New Zealand The scheme of awards for Indian civil servants is to be continued, and recommendations for three fellowships have been accepted for 1962 The report notes that some 50 recipients of the Foundation's fellowships now hold chairs or appointments of similar status in universities overseas Under the Royal Society and Nuffield Foundation Commonwealth Bursaries scheme, to which the Foundation contributes £5,000 a year, 18 bursaries were awarded in 1961

THE NATIONAL CHEMICAL LABORATORY

WHEN the work of the National Chemical Laboratory was last laid open to public view, in October 1960, a good deal of what could then be shown represented the early stages of a thorough-going revision of its objectives Open days were again held this year between September 25 and 28, and provided an opportunity for visitors to the Laboratory to see what progress has been made in the interval On this occasion there was perhaps more scope for the Laboratory to show by the manner of development of its programme that its contribution to the totality of pure and applied chemical research in Great Britain is distinctive and is of the character appropriate to a national laboratory Unquestionably, open days, as a means of bringing the efforts of the Laboratory directly into public notice, are indispensable the large influx of visitors from other Government departments, from industrial laboratories and from universities, colleges and schools makes this quite evident In all, some 129 exhibits were displayed in 55 separate laboratories But to arrange for the movement of large numbers of people through many small laboratories where space is at a premium was a difficult exercise

Research on metallic corrosion is one of the Laboratory's oldest interests, and over the years noteworthy contributions have been made to knowledge of corrosion mechanism and corrosion inhibition A substantial element of the present work is concerned with the microbiological factors that come into play when metals are buried in soil or clay, or exposed to mud or saline and polluted waters Several exhibits illustrated the manner in which field studies are used to supplement controlled laboratory experiments Thus, information is secured which is of the greatest practical value to civil engineers who must devise adequate protection for buried metal structures, pipes or cables A series of sites representative of different soil conditions has been chosen where metals can be buried and left undisturbed over periods of time The soils are examined for resistivity, redox potential, *p*H, uptake of hydrogen, sulphate-reducing bacteria population, etc , and the results are compared with the aggressiveness of the soil as shown by the corrosion of the test metals It has been revealed by laboratory experiments that when the corrosion of iron and steel in waterlogged clay is kept going by bacterial activity, various strains of the bacteria differ in their power to stimulate corrosion, probably through differences in enzyme make-up With many strains, corrosion stimulation is proportional to the hydrogenase activity of the bacteria, but one salt-water strain from California causes rapid corrosion although apparently deficient in this enzyme In collaboration with the Port of London Authority a study is being made of the aggressiveness of Thames water and mud towards unprotected mild steel at different sites along the estuary between Richmond and Southend In these experiments information is being sought on the role (if any) of water-borne pollution

Whether subject to bacterial stimulation or not, corrosion is the resultant of chemical and electrochemical factors, and several exhibits illustrated how these factors are being identified and studied The rate at which oxygen or other reactant is transported by diffusion or convection to a metal surface exposed in aqueous solutions often controls the corrosion process It is not easy to design experiments for defining the hydrodynamic factors precisely, a system amenable to analysis involves the conditions of flow over a metal disk rotating at an accurately controlled speed The adsorption of certain anions on a mild-steel surface is believed to be important in initiating the inhibition of corrosion Methods for measuring the amount of adsorbed phosphate (tagged with a radioactive atom) were shown Adsorption was found to vary with the electrode potential of the steel Electrode potentials of mild steel in aerated solutions of a wide range of electrolytes have shown that all anions stimulate corrosion at low concentrations and all tend to become inhibitive at high concentrations, the concentration at which this change occurs being characteristic of each anion

Primary processes occurring on metal surfaces are studied in the Director's laboratory using the twin techniques of field-emission and field-ionization microscopy Exhibits illustrating both these techniques were presented They allow magnification of more than a million diameters, and the high resolution of the field-ion microscope renders single atoms visible, thus, both techniques allow processes to be examined in atomic detail Condensation of metal vapour on clean metal surfaces in ultra-high vacuum is studied by field-emission microscopy and the field-ion microscope is used to study chemisorption and reaction of gases on metal surfaces

In the Inorganic Group an increasing amount of attention is being devoted to the rare earths Separation processes utilizing ion-exchange chromatography and reduction by sodium amalgam were demonstrated, the latter method being used for the separation of the more readily reducible elements samarium, europium and ytterbium In a search for uses for the rare earths a section has been formed to study the solid-state chemistry of some of the rare earth compounds, particularly the chalcogenides The preparation of rare earth selenides from the anhydrous chlorides and hydrogen selenide was shown together with some preliminary work on phase relationships Equipment for studying adsorption, catalytic activity, electrical and thermal conductivity was on view together with induction-heated furnaces for the preparation and pre-treatment of specimens It is hoped that this work will not only have its applied value but also that it will lead to a fuller appreciation of the characteristics of solids, especially the nature of internal and surface bonding

The Extraction of Metals Group showed the progress it has made in developing a rotary-disk contactor for the solvent extraction of solutes from slurries. A 5-stage unit utilizing 4-ft diameter disks with a processing capacity of 1–2 tons/day was exhibited. This is an element of a full-scale plant. Solvent extraction in the presence of mineral solids can be rendered troublesome by the chemical adsorption of extractants on the solid surface. Measurements of the specific adsorption of amine-type extractants on different minerals have been undertaken. Several exhibits were concerned with the study of processes for the extraction of beryllium from mineral concentrates containing from 2 per cent to $>$ 10 per cent beryllium oxide as beryl. Sufficient understanding of the reactions involved has led to the establishment of conditions under which beryl can be rendered water- or acid-soluble by heating the concentrate with sodium silicofluoride or with calcium carbonate. The variety of products formed by the devitrification of the glasses obtained on melting and quenching beryl-containing materials (on which the subsequent chemical processing depends) was illustrated by results obtained from differential thermal analysis, X-ray diffraction, hot-stage microscopy and cooling-curve studies. Solvent extraction methods have been newly worked out for beryllium. Recovery from sulphate leach liquors by solvent extraction was demonstrated in a continuous counter-current unit, while the possibility of selectively leaching beryllium from suitably sulphated products with aqueous ethanol formed the subject of a further exhibit.

A most interesting new research project was an investigation into high-temperature reactions undergone by solid inorganic compounds introduced as fine particles into flames. Two flame sources were exhibited, one an oxy-acetylene torch and the other a plasma jet through which particles of simple refractory compounds or minerals could be blown continuously. Projected experimental work includes a study of the reconstitution of minerals, carbothermic reduction of minerals to metals and the chemistry of the condensation processes after complete atomization of minerals in flames of suitable temperature. A marked interest in solution equilibria was indicated by a number of exhibits dealing with the use of ultracentrifugation, potentiometric titration, ion-exchange and cryoscopic techniques for the study of the hydrolytic polymers present in solutions of silica, gallium and aluminium salts and spectrophotometric techniques for the study of complex cyanides. Developments in ion-exchange processes were illustrated by the demonstration of a method for the separation of copper, cobalt and nickel by selective elution from a cation-exchange resin with organic solvent-mineral acid mixtures and by anion-exchange resins, prepared by the amination of polyvinylchloride, which show little tendency to absorb silica from acid solution.

For visitors interested in organic chemistry the New Materials Group displayed exhibits illustrating recent progress in four distinct fields of study. These are the organo-metallic chemistry of boron and aluminium with nitrogen, a quest for organic polymers resistant to heat and oxidation, charge-transfer and semi-conduction phenomena, and ion- and electron-exchange polymers. It will be recalled that the original discovery of ion-exchange resins (now so vastly important in chemical technology) was made at the Laboratory some thirty years ago. New compounds (borazynes) based on the $-B=N-$ monomer unit were shown. These are related to borazoles in the same way as *cyclo*-octatetraene to benzene. The chloro compound $[t\text{-BuNBCl}]_4$ is an effective anti-knock, and serves as a starting point for the preparation of other derivatives, for example, the remarkably stable tetra-azide. Work on the preparation of dichloroborazoles and their application to the synthesis of polymers containing the borazole structure has been continued. An achievement worthy of notice is the discovery of tetrameric alazynes, analogous to the tetrameric borazynes above mentioned. A typical example is $[C_6H_5NAlC_6H_5]_4$. X-ray crystallographic data are consistent with two molecular structures—a cubic form or an 8-membered ring of alternate aluminium and nitrogen atoms. The latter would be the first example of π-bonding between aluminium and nitrogen. New technological possibilities exist in a class of organic polymers—the polypyromellitimides, formed from pyromellitic dianhydride and aromatic diamines—remarkable for their thermal and chemical stability. In addition to this synthetic work, the exhibits of the Group illustrated the progress that has been made with physico-chemical studies of ion-exchange resins and membranes and in the characterization of polymers, particularly by the use of gel-filtration. Other exhibits included demonstrations of the use of polarography, electron spin resonance and nuclear magnetic resonance to elucidate the structure and behaviour of charge-transfer complexes and of ion-exchange resins.

The world's common stock of precise physico-chemical (and especially thermochemical) knowledge is the necessary basis both for considering chemical reactions in the research laboratory and for designing processes on the manufacturing scale. The Chemical Thermodynamics Group has been set the task of surveying published data on the thermodynamic properties of substances, identifying deficiencies and undertaking new measurements where these are most obviously needed. Work started earlier on phenols is now being supplemented by work on aliphatic oxygen-containing organic compounds. A programme on inorganic compounds has been initiated which embraces phosphorus compounds and the thermodynamics of non-stoichiometric metallic oxides. The measuring equipment exhibited covers a full range of properties: heat of combustion, low-temperature heat capacity, vapour heat capacity, latent heat of vaporization, vapour pressure, critical temperature pressure and volume, and gas imperfections. The precision of these measurements is the highest attainable. Work on infra-red absorption and Raman spectra—including new work on the observation and identification of frequencies in the far infra-red—was also to be seen, since the computation of thermodynamic properties by the methods of statistical mechanics from vibrational assignments is being developed *pari passu* with their direct measurement.

New exhibits illustrated the measurement of the free-energy of formation of an iron–phosphorus alloy by the study of the vapour pressure of phosphorus above the alloy and free energy measurements on non-stoichiometric oxides by means of solid electrolyte cells. The use of shock tubes for the investigation of high-temperature reactions of inorganic gases could be seen in the Aero-Physics Laboratory of the National Physical Laboratory.

Precise measurements are only meaningful if made on specimens of high purity. Although raw materials can sometimes be bought and purified, considerable ingenuity often has to be exercised in the synthesis of specimens free from troublesome and persistent impurities. The chemical purification of *n*-pentanol and the synthesis of *m*-ethylphenol illustrated some facets of this work. Purification techniques now being used include fractional distillation and freezing, zone melting and sublimation. Purity control is by gas chromatography, mass spectrometry, differential thermal analysis, cryoscopy and high-resolution nuclear magnetic resonance spectroscopy. The above-mentioned techniques are also used to prepare and certify pure materials as 'Standard Samples'. This work was illustrated by the purification of fatty acids for the synthesis of higher paraffins and by the synthesis of compounds in the indane series. An apparatus for ampouling pure gaseous and liquid samples was on display. National Chemical Laboratory Standard Samples supplied by this Group are purchased by industry at the rate of about 400 per year for the calibration of mass and other spectrometers which are in use for the analysis of chemical plant streams.

E. A. Coulson

BROOM'S BARN EXPERIMENTAL STATION

By Dr. R. HULL

On July 27, the Minister of Agriculture, Fisheries and Food, the Right Hon. Christopher Soames, formally opened Broom's Barn Experimental Station, Higham, Bury St. Edmunds, Suffolk, in the presence of about 250 guests. The Right Hon. the Earl of Radnor, chairman of the Lawes Agricultural Trust Committee, welcomed the Minister and invited him to open the Station, and Sir Peter Greenwell, chairman of the Sugar Beet Research and Education Committee, thanked the Minister.

Broom's Barn farm was acquired in 1959 by the Lawes Agricultural Trust Committee, the governing body of Rothamsted Experimental Station, and has been developed as a research station to study sugar beet growing. The land, new farm buildings and laboratories have been paid for by grants amounting to nearly £250,000 from the Ministry of Agriculture's Sugar Beet Research and Education Fund, to which both sugar beet growers and the British Sugar Corporation, Ltd., subscribe.

Broom's Barn Experimental Station replaces the Rothamsted Field Station, Dunholme, near Lincoln, where research for the Sugar Beet Research and Education Committee has been carried out since 1947. Work on diseases of sugar beet, which began at Hackthorn in Lincolnshire in 1935 in association with the Midland Agricultural College, became a charge of Rothamsted Experimental Station after the Second World War and a field station was established in temporary buildings on a disused airfield at Dunholme. The work extended to include the manuring and pests of sugar beet, but was handicapped by lack of land and suitable buildings.

The ultimate aim of all the work is to improve the health and yields of both the root and seed crops. To this end, field experiments and observations, supported by the necessary glasshouse and laboratory work, are made to elucidate the biology of pests and pathogens, to assess the damage they cause, and to find how the losses can be lessened. The research workers co-operate closely with the field staffs of the sugar factories in field experiments, in recording the incidence of pests and diseases, in organizing a spray-warning scheme to advise growers when to spray the crops against aphids that threaten to spread yellows, and in the certification of mangold and sugar beet stecklings.

The work on manuring aims at ensuring that fertilizers are used most efficiently and economically. Each year many field experiments, performed in conjunction with the British Sugar Corporation, test responses to a range of fertilizers applied in different ways. Laboratory methods of forecasting these responses are investigated. This work will continue and be expanded at Broom's Barn, where it will also be possible to do long-term experiments on the effect of fertilizers, cultivations, crop rotations and agricultural chemicals (weed killers, insecticides and fungicides), and to study irrigation of sugar beet.

The Buildings

The new buildings consist of an administrative block with offices, library, meeting hall and mess room (3,740 sq. ft.), chemistry and biological laboratories (4,040 sq. ft.), field laboratories (3,700 sq. ft.), tarehouse (3,000 sq. ft.), glasshouses (2,830 sq. ft.), cloakrooms (790 sq. ft.), circulation areas (1,650 sq. ft.) and a service block (2,160 sq. ft.). There are five cottages for Staff and a house for the Head of the Station (Dr. R. Hull).

The buildings were designed by Cowper, Poole and Partners, Chartered Architects, to blend into the open Suffolk landscape. The choice of the traditional rural pantiles as roofing set limits on the pitch of roofs and width of buildings. The layout of the buildings and their interior design give flexibility and allow for expansion should this prove necessary. The service mains within the buildings are at high level and have a 'fishbone' layout, so that they are easily accessible and altered. The courts between buildings give sheltered outside working space—a boon on this windswept exposed site.

In the administrative building the offices occupy the south side, the library, mess room and cloakroom the north and the meeting hall lies between them. This airy hall, with underfloor heating, will seat more than 200 people. It will be used only occasionally for such large audiences, so the furnishings have been designed to divide it into parts suitable for small conferences, staff meetings or demonstrations.

The laboratory building provides a large chemistry and a biology laboratory with eight smaller laboratories on the south side. The north-facing, large laboratories are lit by the south-facing clerestory windows. The circulation area is cut off from the laboratory only by pillars, an arrangement which avoids tunnel-like corridors. There are a photographic studio and dark room, balance room, chemical dark room, inoculation room and medium room and main store.

The field laboratory is the same basic construction as the main laboratory, but has a cheaper finish.

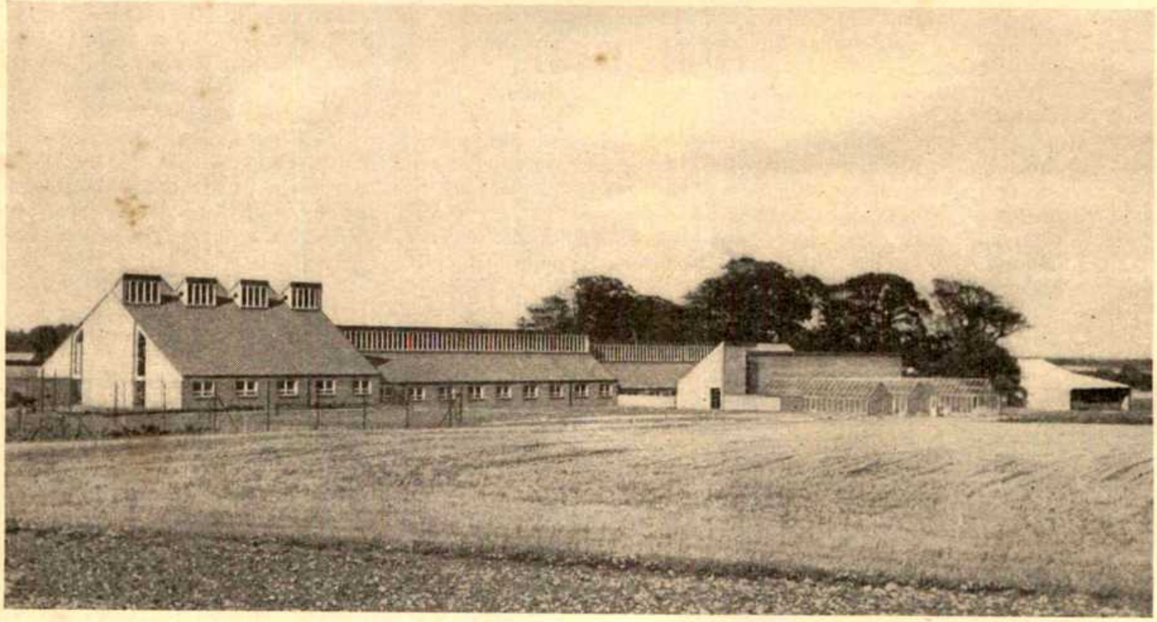

Fig. 1. View of Broom's Barn Experimental Station from the south-west. From left to right are the administrative building, laboratories, field laboratories, and tarehouse. In front of the latter is the headerhouse with four compartmented glasshouses. On the right, among the trees, are the farm buildings

It contains a room for preparing and storing potting-soil, a soil-sample store, an area for drying, treating and storing seed, a general reception area and a laboratory.

The adjoining tarehouse has the sample reception and storage platform at high level and the machinery at low level. The two washers use recirculated water from a settling pond situated near the farm buildings. One of the spray washers serves an automatic line in which the roots are not handled after being tipped into the washer hopper; from the other, the roots are delivered to baskets on roller conveyors so they can be examined, topped, etc., after washing. Both lines feed a multiple saw, and the dross is delivered into a lorry or heap outside. The brei from the saws goes for test of sugar content and juice purity into the adjacent tarehouse laboratory, which is part of the field laboratory.

The Farm

The farm lies 230–280 ft. above sea-level and consists of 190 acres in a rectangle approximately 1,200 yd. by 770 yd. The soil is glacial deposit over chalk. On the north side of the farm it is light and sandy (Moulton and adjoining series) grading through medium loam with flints (Newmarket and Ashley series) to a heavy loam (Stretham series) as the land rises to the south.

The old farm dirt tracks have been ploughed and a concrete road laid to give access to the farm buildings and to all fields. There is a concrete beet-loading platform at the south end of the farm. All but one of the eleven fields into which the farm has been divided are roughly rectangular and most boundaries are parallel to the sides of 5-chain grid squares, marked by permanent sockets around the farm boundary. Soil samples have been taken from each square chain, analysed for available phosphorus, potassium, *p*H and organic matter and stored for future reference.

A 5-in. irrigation main runs the length of the farm, and temporary surface mains can be taken from hydrants to irrigate any part. The water is pumped electrically from a 400 ft. borehole near the farm buildings, which yields more than 12,000 gallons per hour, enough to irrigate 2 acres at a time, and also supplies the buildings. The pumping mechanism is arranged so that experimental watering can be done from the irrigation main at a delivery rate much lower than that needed for farm crop irrigation.

The farm buildings are surrounded by a concrete apron. The old timber Broom's Barn is used for storage, and a new general purpose building (2,250 sq. yd.) is used for machinery, workshop and storage. A new covered cattle yard (6,750 sq. ft.) has a centrally placed self-fed silage silo for feeding 80 bullocks in winter. The pumphouse, tarehouse settling pond and sewage plant are near the farm buildings.

The current farming system aims to get the land into good condition for experiments. The basic crop rotation is sugar beet, three cereals and temporary ley, but each field in turn carries a silage crop for cutting in June, after which it is fallowed. This will help to free the land of a heavy weed infestation.

At present, the sugar beet crop provides the site for annual experiments on the control of downy mildew (*Peronospora schachtii*), chemical weed control, the use of insecticides as seed dressings, soil applications and sprays for controlling aphids and virus yellows, testing and selecting yellows-tolerant varieties and the effect of nitrogen and sowing date on yield. Experiments on the cereal crops determine nitrogen responses. When the land is clean and in good condition, long-term experiments will be started. The experiments will be designed to investigate sugar beet as a crop of the rotation and determine how treatments applied to it affect following crops and how treatments applied to previous crops affect the sugar beet. A subject of immediate importance for investigation is the sugar percentage and juice purity of beet, both of which have decreased as the yield of beets and sugar have increased in recent years.

HYDRAULICS RESEARCH STATION, WALLINGFORD

"WERE water a perfectly non-viscous inelastic fluid, whose particles, when in motion, always followed sensibly parallel paths, hydraulics would be one of the most exact of the sciences. But water satisfies none of these conditions, and the result is that in the majority of cases brought before the engineer, motions and forces of such complexity are introduced as baffle all attempts at a rigorous solution."

These words, written in 1908 by the late Prof. A. H. Gibson, might still serve as a *raison d'être* for the science of experimental hydraulics and for the large research stations at (for example) Delft, Vicksburg, Grenoble and Wallingford. Such stations are largely concerned with problems in free-surface hydraulics, but when one expresses this academic phrase in terms of water-supply, flood prevention, and sea defences, its impact on everyday life becomes apparent. One needs only to think of drought at any time or place, the catastrophic floods at Lynmouth, or the *seiches* of the North Sea in 1953.

So much for the reality of the problems demanding experimental study. But the cost of experimentation on the full scale is generally too high in money and, perhaps, in lives. Thus, most of this laboratory work is scaled down in space and time, so that the accuracy of the results depends on the degree of dynamical similarity achieved.

*Hydraulics Research 1961** embodies the annual report of the Hydraulics Research Board and the report of the Director of Hydraulics Research, and in 90 pages summarizes the work of the Hydraulics Research Station, Wallingford, for the year. There is a brief section on hydrological research, an activity to be developed considerably after the attachment to the Station of a special Hydrological Research Unit. This unit is expected to concern itself particularly with the problem of rainfall and run-off in natural catchments. Such a development, clearly of national importance, will be widely welcomed. Much of the hydraulic work undertaken is necessarily of an *ad hoc* nature, in the sponsored solution of diverse practical problems. Nevertheless, there is evidence of a fundamental approach, for example, to the question of dynamical similarity in sediment transport, and again in the study of vortices.

It is stated that about one-half of the sponsored schemes originate overseas, so that the Station has already attained a measure of international recognition: its work, in fact, may be compared with that of the Waterloopkundig Laboratorium at Delft. The principal study-groupings are: *hydraulic structures* (including interesting reports on critical-depth gauging-flumes, vortex formation at intakes, and hydro-pneumatic ship-fenders), *unidirectional channel flow* (including, for example, the measurement of sand transport with the aid of radioactive tracers), *estuarial studies*; *waves and sea defences* (including full-scale field studies of littoral drift, and laboratory studies of the forces exerted by waves and currents on a submarine pipe), and there are short sections on *instrumentation and mechanization* which might usefully be expanded in future years.

These casual references do little justice to the variety of the problems studied (in fact, no fewer than forty projects are summarized in the booklet), and the ingenuity with which they are tackled can only be appreciated after a careful reading.

There is a useful appendix listing the papers written during the year by members of the Station staff, which will enable readers to follow up particular topics in greater detail. R. B. WHITTINGTON

NUTRITIONAL PREFERENCES AMONG THE NIGERIANS

THE West African Science Association was founded in 1953. Although its members were distributed throughout West Africa, they were predominantly resident in Ghana, where all its activities took place. It had been felt for some time that similar activities should take place in Nigeria, and, in May 1957, a circular was dispatched to as many scientists as possible resident in or near Ibadan. The replies received were mainly in favour of the formation of an Ibadan Branch of the West African Science Association though many persons preferred the formation of an independent association in Nigeria. A meeting was held on October 25, 1957, at which it was agreed that an organization to bring scientists together should be formed in Nigeria and should, if possible, be associated with the West African Science Association. This was later agreed, and the inaugural meeting of the Association was held in December 1958. The Proceedings of the Association have now been published, the first volume covering the first three years of its existence*.

It contains summaries of many important articles, among them being one by Dr. W. R. Stanton of the Ministry of Agriculture, Regional Research Station, Samaru, Zaria, dealing with future changes in preference among Nigerian peoples for locally grown foodstuffs.

Preference is divisible into two types—rational and irrational. The author suggests that the study of the 'irrational' causes of preferences is equally important to that of the study of 'rational' causes. These may be listed as follows:

Irrational factors (namely, those ethnobotanically or animistically developed or a result of the cultural development of the community): (1) religious dictates, (2) animistic taboos, (3) archaic survivals of the eco-biological evolution of society, (4) traditional methods of preparations and uses, (5) prestige and status value, (6) attractiveness (in the sense that attractiveness can be the result of conditioning).

Rational factors: (1) availability and price, (2) palatability alone and with other foods (palatability, however, is subject to conditioning), (3) ease of culture, harvesting, preparation, storage, handling and marketing; yielding ability, appropriate developmental time in relation to climate, soil and water, (4) use of the plant as a whole (gross as distinct from net utility).

---

* Science Association of Nigeria. Proceedings, Volumes 1–3, 1958–1960. Edited by Dr. B. Hopkins. Pp. 78. (Ibadan: Science Association of Nigeria, 1962.) 5s. 6d.

Stanton cites examples of the operation of these various types of preference particularly within and between different types of cereal grown in Nigeria. In studying the variation within and between the food crop species in a country, correlation with the biological factors (a convenient index for which is the ecological zone) is incomplete and a useful stratification is provided by maps showing the cultural units of Nigeria such as those defined previously by Buchanan and Pugh. The author compares interaction with the ecological zone of the strongly developed 'sorghum' culture of the savannas of West Africa with the development of grain cultures in equivalent zones in East Africa.

He suggests that present observed preference should not be the sole means of determining the development policy for food crops (species and type), but that account should be taken of the trend of preference as shown in more developed countries, of the weakening of religious ties and tribal taboos and of the increasing awareness of the urban elements of the community of the 'expressed preference' in other countries.

Lack of accurate statistics on food crop production of less-developed territories is becoming of increasing concern and the need for more data prior to development planning has been stressed by the Food and Agriculture Organization. This lack of data applies to Nigeria. Nigeria is favourably placed at present in respect of potential productivity in relation to the present population. This is a general situation, but signs of over-population, at present levels of agriculture, are already apparent in parts of the Eastern Region and Katsina and Sokoto Provinces in the Northern Region. It is also shown that the mean rate of population increase was approximately 2 per cent per annum. This figure is higher than that of any other West of Equatorial African territory.

If such a rate of increase is maintained without a concomitant rate of increase of productivity (which postulate demands a higher rate of increase of productivity than at present), it would vitiate any predictions of changes in the consumption of food crops based on comparison with that of more developed countries, since opportunities to develop a balanced, highly productive, high plane of nutrition agriculture would be superseded.

Other partially developed countries differ in their attitude to the awareness of a close approach to saturation-levels of population, and Stanton contrasts the educational and developmental policies of India and Japan. The latter country is far in advance of others in the active control of population structure by education and birth control, and an assessment of the probable future attitude of a people to such measures is of overriding importance in predicting a country's development.

CHEMISTRY, TOXICOLOGY, PHARMACOLOGY AND MICROBIOLOGY OF A NEW ACID-STABLE PENICILLIN, RESISTANT TO PENICILLINASE *(BRL.1621*)*

By J. H. C. NAYLER, A. A. W. LONG (Chemistry), D. M. BROWN, P. ACRED (Toxicology and Pharmacology), G. N. ROLINSON, F. R. BATCHELOR, SHIRLEY STEVENS and R. SUTHERLAND (Microbiology)

Beecham Research Laboratories, Ltd., Brockham Park, Betchworth, Surrey

THE use of methicillin, 2,6-dimethoxyphenyl penicillin, in the treatment of infections caused by penicillinase-producing strains of staphylococci is now well established in clinical practice. Its one disadvantage is that it must be given by injection since it is unstable in acid solution and poorly absorbed from the gastrointestinal tract. This article describes a new penicillin which does not suffer from this defect, and is, moreover, active at lower concentrations than methicillin. Clinical investigations are being reported concurrently elsewhere[1].

Chemistry

Acylation of 6-aminopenicillanic acid with reactive derivatives of several types of sterically hindered carboxylic acid gives penicillins which resist inactivation by penicillinase. These penicillins vary considerably in their chemical and antibacterial properties, and a particular class which combines resistance to both penicillinase and mineral acid with useful activity against most Gram-positive bacteria consists of 3,5-disubstituted 4-isoxazolyl penicillins (I). The preparation of two such penicillins, *BRL* 1400† ('Oxacillin') [I, $R = C_6H_5$, $R' = CH_3$] and its isomer, *BRL* 1454 [I, $R = CH_3$, $R' = C_6H_5$], has been described in detail[2]. Many other penicillins of type (I) have been prepared[3] and examined, and one of them, 3-o-chlorophenyl-5-methyl-4-isoxazolyl penicillin [II, *BRL* 1621], has been selected as the compound of choice.

BRL 1621 is available as the sodium salt monohydrate, which forms a colourless microcrystalline

powder It is freely soluble in cold water to give a solution stable at 5° C for one week A 1 per cent solution in water has $[\alpha]_D^{20}$ + 163° and *p*H of 6 0–7 5 The half-life in solution in 50 per cent aqueous alcohol at *p*H 1 3 and 35° C as determined by a previously described method[4] is 160 min, which is approximately equal to that of *BRL* 1400 and penicillin V

Animal Studies, Toxicology and Pharmacology

Protection tests The protective effect of *BRL* 1621 against the penicillin-resistant *Staphylococcus pyogenes* Russell (type 80) was estimated using the method of Selbie and O'Grady[5] as modified by Brown and Acred[6] Groups of 10 mice (18–22 g) were infected by injecting into the muscle sheath of the thigh 0 2 ml of a 1/2 dilution of an overnight growth of *Staphylococcus pyogenes* Russell *BRL* 1621, methicillin and penicillin *G* were administered in doses of 200 and 50 mg/kg orally and subcutaneously, daily for three days, the first injection being given immediately following the infection An infected control group received no treatment The maximum thigh diameter of each mouse was measured with calipers on the first, second, third and sixth day after infection The results are expressed as the percentage protection calculated in the following manner

$$\frac{\text{mean daily thigh enlargement infected controls} - \text{mean daily thigh enlargement penicillin group}}{\text{mean daily thigh enlargement of infected controls}} \times \frac{100}{1}$$

Acute toxicities The acute oral, subcutaneous and intravenous toxicities were determined in male mice (18–22 g), 10 mice being used at each dose level The LD_{50} values (g/kg) for the various routes were respectively > 5 0, 3 0 and 1 2 g/kg

Prolonged tests (1) *Rats* *BRL* 1621 was administered orally and subcutaneously to groups of 12 male rats over a period of 12 weeks at doses of 500 and 100 mg/kg A control group of rats received 0 2 ml /100 g normal saline subcutaneously

During the test, daily weights and food intake were recorded Weekly observations were made of packed cell volume, white cell counts, and qualitative tests for proteins, sugars and occult blood were carried out on urine specimens Spectroscopic examination of the blood of the rats in all groups and hæmoglobin concentration was determined on the last week of the experiment

All rats were killed at the end of the test and post-mortem examinations made Weights of the spleens, livers, kidneys, adrenals and testes were recorded In addition to determination of organ weights at autopsy, the following tissues were removed for histological examination salivary gland, lymph node (mesenteric), thymus, thyroid, heart, lung, liver, kidney, adrenal, spleen, testes, bone marrow, stomach, duodenum, pancreas and small intestine The tissues at the site of injection were also removed No hæmatological, biochemical, histological or organ weight abnormalities were observed Macroscopically the only untoward effect was small areas of necrosis noted at the site of injection in the rats receiving *BRL* 1621 500 mg/kg subcutaneously These tissue reactions were only seen during the first 3 weeks of the test after which time they disappeared.

Table 1 PERCENTAGE PROTECTION BY *BRL* 1621, METHICILLIN AND PENICILLIN *G* IN MICE INFECTED WITH *Staph pyogenes* RUSSELL (PENICILLIN-RESISTANT)

Penicillin	Dose (mg/kg)	Per cent protection	
		Oral	Subcutaneous
BRL 1621	200	98 3	97 6
BRL 1621	50	58 6	83 9
Methicillin	200	Inactive	84 7
Methicillin	50	Inactive	40 2
Penicillin *G*	200	Inactive	Inactive
Penicillin *G*	50	Inactive	Inactive

(2) *Dogs* *BRL* 1621 was administered in doses of 2,000 and 500 mg/kg twice daily to groups of 3 dogs for a period of 4 weeks The following biochemical and hæmatological estimations were made at the beginning and end of the test ESR (mm/h), PCV (per cent), Hb G (per cent), reticulocytes (per cent), MCHC (per cent), total white cell count and differential count, blood urea (mg per cent), blood glucose (mg per cent) serum proteins—total, albumin, α_1-, α_2-, β- and γ-globulins, alkaline phosphatase KA units, SGPT units and presence of bilirubin At autopsy the following organs were weighed brain, heart, lungs, liver, spleen, pancreas, kidneys, thyroids, adrenals and gonads In addition to these, the histology included examination of stomach, ileum and colon, cervical and mesenteric lymph glands, salivary glands, skeletal muscle and bone marrow No hæmatological, biochemical or histological abnormalities were noted

Local toxic effects There were no observable tissue reactions to intradermal and intramuscular injection of 1 per cent solutions of the penicillins in groups (3 per group) of guinea pigs and rats 3 days after the injection The only observable reactions to administration of 10 per cent solutions were a hardening of the skin and erythema around the sites of the intradermal injections

Following the subconjunctival injection in rabbits of 0 5 ml of a 50 per cent solution, *BRL* 1621 penetrates into the aqueous humor but an opacity of the cornea develops which persists for at least 14 days with only a slight decrease in the intensity. It would appear, therefore, that *BRL* 1621 is contraindicated for ophthalmological use

General pharmacology The effect of *BRL* 1621 on the blood pressure and respiration was determined in the anæsthetized cat

Four cats were anæsthetized with a chloralose (1 per cent) urethane (5 per cent) mixture Doses of up to 100 mg/kg administered intravenously had no effect on the blood pressure but doses in excess of

BRL 1400							36	74	87	20	12	1	
BRL 1621							2	66	116	40	5		1

this up to 400 mg/kg had slight hypotensive effects which usually did not exceed 10 mm mercury.

The responses to adrenaline (5·0 μg), acetylcholine (0·2–0·5 μg), histamine (0·5–5·0 μg), were unaffected by doses of 200 mg/kg of *BRL* 1621. Repeated doses of *BRL* 1621 at 5-min intervals increasing from 25, 50, 100, 200 and 400 mg/kg were given. Death occurred when the cat had received a total of 1·6 g/kg.

BRL 1621 penetrates poorly into the C.S.F. After a dose of 500 mg/kg intramuscularly in rabbits the concentration in the C.S.F. was no greater than 2·3 μg/ml 1 h after administration, while the corresponding serum concentration was 370 μg/ml.

BRL 1621 is eliminated from the body by excretion in high concentration both in the bile and urine of rats. After the oral administration of 100 mg/kg 18·7 per cent is recovered in the urine after 24 h, while after intramuscular administration 42·1 per cent is recovered. 10·2 per cent of the orally administered antibiotic can be accounted for in the bile.

Metabolism in animals. Paper chromatographic examination of the urine collected over 24 h from rats which had received 100 mg/kg *BRL* 1621 intramuscularly, indicated the presence, in small amounts, of two metabolites. Further investigation of these substances is in progress.

Microbiology

Antibacterial activity. Minimum inhibitory concentrations (M.I.C.) for bacteria were determined as described previously[7]. It will be seen from Table 2 that *BRL* 1621 is highly active against *Staph. aureus, Strep. pyogenes, Strep. viridans* and *Strep. pneumoniae*, but against *Strep. faecalis* and the Gram-negative bacilli the level of activity is very low. Penicillin-sensitive staphylococci were usually inhibited by 0·1–0·25 μg/ml. *Strep. pneumoniae, Strep. viridans* and β-*haemolytic Streptococci* were usually inhibited by 0·1 μg/ml.

Penicillin *BRL* 1621 is primarily of interest for its activity against penicillin-resistant staphylococci. Results in Table 3 show that *BRL* 1621 is appreciably more active than methicillin in this respect. Results for the activity of *BRL* 1621 against a larger number of hospital strains of *Staph. aureus* are shown in Table 4. The total of 382 cultures tested comprised 152 penicillin-sensitive (penicillin G M.I.C. < 0·1 μg/ml) and 230 penicillin-resistant (penicillin G M.I.C. 0·1 μg/ml or greater). Taking the penicillin-sensitive strains, only one required a concentration of *BRL* 1621 as high as 1·25 μg/ml to inhibit growth and approximately 95 per cent of the strains showed M.I.C. values in the range 0·05–0·25 μg/ml. Of the total of 230 penicillin-resistant strains only two required a concentration as high as 1·25 μg/ml for inhibition and 97 per cent of the strains showed M.I.C. values in the range 0·125–0·5 μg/ml. The largest single group of strains were those with an M.I.C. value of 0·25 μg/ml.

Comparative results are also included in Table 4 for *BRL* 1400 (oxacillin). It will be seen that *BRL* 1621 is slightly more active than *BRL* 1400. Of the total of 230 penicillin-resistant strains, only two showed an M.I.C. as high as 1·25 μg/ml with *BRL* 1621, whereas with *BRL* 1400 the corresponding number of strains was 36 (15 per cent).

Determination of M.I.C. values in solid media and in broth give similar results and M.I.C. values are not significantly influenced by inoculum size.

Effect of serum on activity. Activity of *BRL* 1621 is depressed by the presence of human serum to an extent somewhat greater than is the case with methicillin. Results are shown in Table 5 for 36 strains of staphylococci. In the absence of serum all were inhibited by 0·5 μg/ml *BRL* 1621 or less and most of the strains were inhibited by 0·25 μg /ml. In the presence of human serum, however, the majority of the strains required 1·25 μg/ml to prevent growth. It will be seen from Table 5 that *BRL* 1400 is also influenced by serum, the extent being similar to that with *BRL* 1621.

Table 5. Activity of *BRL* 1621 compared with *BRL* 1400 in Tests with and without Human Serum, using 36 Strains of Staphylococci recently isolated clinically

	Serial dilution in agar M.I.C. μg/ml and number of strains 5·0 and over	2·5	1·25	0·5	0·25	0·12	0·05	0·02 and below
Penicillin *G*	20		7		2		3	4
BRL 1621				8	21	6	1	
BRL 1621 +			23	10	3			
BRL 1400				13	17	3		
BRL 1400 +		3	28	5				

+ denotes agar containing 40 per cent human serum

Bactericidal activity. Viable counts in broth cultures containing *BRL* 1621 were carried out in a manner similar to that of Miles, Misra and Irwin[8]. Penicillin *BRL* 1621 is highly bactericidal to penicillin-resistant staphylococci at concentrations only slightly higher than the M.I.C. values. In bactericidal tests *BRL* 1621 is substantially more active than methicillin and also slightly more active than *BRL* 1400. At a concentration of 2·0 μg/ml *BRL* 1621, a kill of approximately 99·9 per cent is obtained in 7 h in broth cultures of penicillin-resistant staphylococci.

Activity of BRL 1621 by the paper disk method. Whatman antibiotic assay disks 6 mm diameter were used with two levels of *BRL* 1621, 2 μg and 5 μg per disk. Nutrient agar plates were inoculated with the test organism to result in dense but non-confluent growth and the dishes were left at room temperature for 3–4 h with the disks in place before incubating at 37° C overnight. For a range of staphylococci of varying penicillin *G* sensitivity the zone diameters with *BRL* 1621 showed a fairly good correlation with the M.I.C. values for the strains. Using a 2 μg disk the zone diameters ranged from 19–29 mm, depending on the strain, and with a 5 μg disk the range was 22–33 mm diameter, including the diameter of the disk. Very heavy inoculum, and

Table 6 Stability of *BRL* 1621 to Staphylococcal Penicillinase Compared with *BRL* 1400 and Methicillin

60	0 (820)	1,520	800	250

* Penicillinase at a dilution of 1/200

particularly the presence of blood in the agar, results in smaller zone diameters

Stability to penicillinase A penicillinase-producing strain of *Staph aureus* was grown as described previously[7], and the whole culture, including the cells, was used as enzyme The tests on penicillinase stability of *BRL* 1621, *BRL* 1400 and methicillin were carried out at two levels of substrate, 50 μg/ml and 2,000 μg/ml One volume of the enzyme was added to two volumes of phosphate buffer, *p*H 7, containing the penicillin The reaction mixture was incubated at 37° C and assays carried out at intervals of time Because of the extreme instability of penicillin *G* to penicillinase, a parallel test was carried out with penicillin *G* in which the penicillinase was present at a given dilution since with the penicillinase at the concentration used for the methicillin and isoxazole tests the penicillin *G* was destroyed almost instantaneously It will be seen from Table 6 that *BRL* 1621 is extremely stable to penicillinase although slightly less stable than methicillin, and that *BRL* 1621 is slightly more stable than *BRL* 1400 It should be noted that the penicillinase stability of *BRL* 1621, and also that of *BRL* 1400 and methicillin, is greatly influenced by the concentration of the compound present in the test With these compounds, the concentration of substrate is a limiting factor for penicillinase activity except at very high concentrations and the stability of these compounds is largely due to this effect of substrate concentration on rate of enzyme action Consequently, the lower the concentration of these penicillins the more stable they become to penicillinase

Penicillin *BRL* 1621, like methicillin, is a powerful inducer of penicillinase formation

Emergence of resistance to BRL 1621 By repeated sub-culture of staphylococci in the presence of *BRL* 1621, resistant strains can be selected out in a step-wise manner similar to that seen with penicillin *G*, methicillin and other penicillins Single step mutants of high resistance to *BRL* 1621 have not been encountered in laboratory experiments with staphylococci On the other hand, naturally occurring staphylococci resistant to methicillin[9] are also resistant to *BRL* 1621, although since *BRL* 1621 is a more active compound the M I C values with *BRL* 1621 against these resistant strains are lower than those for methicillin This means that although the M I C values for methicillin may be above the serum levels normally obtained, the same may not be the case with *BRL* 1621 For example, certain strains showing M.I C values of 12 5–25 μg/ml with methicillin were found to be still sensitive to 1·25 μg/ml *BRL* 1621 In general, the highly resistant strains which showed M I C values of 125 μg/ml and over with methicillin, also showed M I C values with *BRL* 1621 above the concentrations obtainable in the body but one strain showing an M I C value of 50 μg/ml. with methicillin was still sensitive to 1 25 μg/ml *BRL* 1621

Metabolite of BRL 1621 After administration of *BRL* 1621, either orally or intramuscularly, in normal human subjects a small proportion of the compound undergoes a metabolic change in the body to give rise to another penicillin This metabolite is present in the serum as well as in the urine, and in human beings approximately 10 per cent of the penicillin excreted is in the form of the metabolite A similar metabolite also occurs with *BRL* 1400

The metabolite of *BRL* 1621 has been isolated and found to have antibacterial activity very similar to *BRL* 1621 itself Moreover, using *Sarcina lutea* and also a penicillin-resistant staphylococcus as test organism, *BRL* 1621 and the metabolite both have the same ring-diameter concentration relationship in the cup-plate assays

In view of the very close similarity in the biological properties of the metabolite and *BRL* 1621 itself, and also in view of the small amount of the metabolite formed it seems quite certain that the latter does not in any way complicate the determinations of serum levels or the general evaluation of *BRL* 1621

We wish to acknowledge the guidance accorded by Mr F P Doyle, director of research, Brockham Park, in the preparation of the manuscript We also thank our many colleagues who assisted in the work discussed in this article

COMPOSITION OF CIGARETTE SMOKE : SOME LOW-BOILING COMPONENTS

By Dr R. A W. JOHNSTONE, P M QUAN and Dr W CARRUTHERS
Medical Research Council Carcinogenic Substances Research Unit, University of Exeter

CIGARETTE smoke condensate contains a fraction, volatile in methanol vapour, from which dipentene has been isolated[1] The use of preparative scale gas chromatography has enabled us to isolate and identify from this fraction a number of other constituents (Table 1)

Benzene and toluene have been detected in, but not isolated from, the gaseous phase of cigarette smoke[2], and claims based on scanty evidence have been made for the presence of 2,5-dimethylfuran (ref 3), 1,3,5-trimethylbenzene and 1,2,4-trimethylbenzene (ref 4)

The methanol volatile fractions from Russian (flue-cured tobacco) and Argentinian cigarettes ('black' fermented tobacco) were compared quantitatively by analytical gas chromatography with the corresponding fraction from British cigarettes (flue-cured tobacco) As shown in Table 1, the results are broadly similar except for the notably low content of 2,5-dimethylfuran in the smoke from Argentinian cigarettes This is probably related to the low carbohydrate content of fermented tobacco

Table 1

Substance isolated	Yield, μg/cigarette British (av wt 1 15 g)	Russian (av wt 1 01 g)	Argentinian (av wt 0 99 g)
Benzene	27	48	12
2,5-Dimethylfuran	45	48	3 5
Toluene	46	164	65
Ethylbenzene	7	20	7
m-Xylene	30	48	20
o-Xylene Styrene	22	48	20
F 5 (*a*)	32	43	23
Mesitylene	9	11	8
ψ-Cumene	11	14	7
Dipentene	200	165	126
p-Isopropenyltoluene	11	—	—

The substances listed in Table 1 do not occur in tobacco, and their origins were investigated in a number of experiments carried out with modified cigarettes, types I–V Complete extraction of British cigarettes with petrol had little effect on the composition or amount of the methanol volatile fraction (Table 2) Further complete extraction with methanol caused marked reductions in the yields of dipentene and 2,5-dimethylfuran, but the amounts of the remaining components were only slightly affected The precursor of dipentene was in a chloroform-soluble fraction and that of 2,5-dimethylfuran in a water-soluble fraction of the methanol extract

Table 2

Substance	Cigarettes Ordinary Type I	Petrol extracted Type II	Methanol extracted Type III	Water-soluble part added Type IV	$CHCl_3$-soluble part added Type V
Benzene	27	23	20	22	39
2,5-Dimethylfuran	45	35	10	25	8
Toluene	46	57	42	54	67
Ethylbenzene	7	9	8	12	10
m-Xylene	30	31	12	15	28
o-Xylene Styrene	22	21	13	21	19
F 5 (*a*)	32	31	6 5	7	32
Mesitylene	9	11	1	3	10
ψ-Cumene	11	11	3	11	11
Dipentene	200	163	11	22	160
p-Isopropenyltoluene	11	11	—	—	3

Figures refer to yields in μg/cigarette

Dipentene could arise by the dimerization of isoprene which is present in cigarette smoke, but it has been found[5] that this reaction yields, among other products, almost equal amounts of dipentene and its isomer *m*-mentha-1,8-diene The latter could not be found in cigarette smoke

The presence of the precursor of 2 5-dimethylfuran in a water-soluble portion of the cigarette tobacco increases the probability that it is a carbohydrate

The remaining aromatic substances listed in Table 1 appear to arise from complex insoluble components of tobacco, as, for example, the lignins, proteins and higher carbohydrates Carotenes, known to yield *m*-xylene on pyrolysis[6], may be a source of some of the *m*-xylene in smoke

Preparation of methanol-volatile fraction of cigarette smoke Uncased British cigarettes containing a blend of flue-cured tobaccos were smoked mechanically with a 2-sec puff of 25 ml every 15 sec The mainstream smoke from 25,000 cigarettes was collected at – 70° and the condensate dissolved in ether–methanol (1 · 1) The solvents were distilled off, and further quantities of methanol were repeatedly distilled from the residue until no more material co-distilled The combined distillates were diluted with a large volume of water and the ether layer was washed several times with water and dried (calcium chloride) Distillation of the ether gave a pale yellow liquid (77 g), b p approximately 60–200°, which was filtered through a column of 250 g of alumina (neutral, Brockman grade I) Elution with petrol (b p 40°–45°) and removal of the solvent by distillation through a Vigreux column gave 16 9 g of a mobile yellow liquid (*M*) Sodium fusion tests for nitrogen, sulphur and halogen were negative Gas chromatographic and infra-red analyses showed that chromatography on alumina had removed constituents containing hydroxyl and carbonyl groups, but had not altered the amounts of the residual substances

Gas chromatography of the petrol eluate, M The liquid *M* was gas chromatographed at 150° with a nitrogen flow of 100 ml /min on a 6 ft × 1 in column of 30–60 mesh brickdust (*C*22, Johns–Manville) coated with 20 per cent by weight of a silicone elastomer (*E* 301, Imperial Chemical Industries, Nobel Division) Seven fractions, *F*'s 1–7, were collected by cooling the effluent to – 70°. These fractions, corresponding to peaks on the gas chromatogram, were examined in more detail by gas chromatography on a 15 ft × ¼ in column of 30–60 mesh brickdust coated with 20 per cent 'Apiezon *M*' grease, at 95° and an argon flow of 40 ml /min Fractions *F* 4 and *F* 5 were mixtures and were rechromatographed to obtain fractions richer in the individual components Identifications were based on gas chromatographic and infra-red data The results are summarized as follows

F 1 Benzene, confirmed by ultra-violet absorption

F 2 2,5-Dimethylfuran, with 2,4-dinitro-phenylhydrazine and sulphuric acid it gave acetonylacetone *bis*-2,4-dinitro-phenylhydrazone, m p and mixed m p 261–262°

F 3 Toluene, 2,4-dinitro-derivative m p and mixed m p 70°.

F 4 (*a*) Mixture of *m*-xylene and ethylbenzene Nitration of the mixture and crystallization from ethanol afforded 2,4,6-trinitro-*m*-xylene, m p and mixed m p 182–184°
(*b*) Mixture of *o*-xylene and styrene Bromination of the mixture and sublimation of the product at 50°/5 mm gave styrene dibromide, m p and mixed m p 71–73°

F 5 (*a*) Mixture of unsaturated aliphatic compounds, containing vinyl groups
(*b*) 1,3,5-Trimethylbenzene, confirmed by nitration to 1,3,5-trimethyl-2,4,6-trinitro-benzene, m p and mixed m p 236°
(*c*) 1,2,4-Trimethylbenzene characterized as the 3,5,6-trinitro-derivative, m p and mixed m p 185°

F 6 Dipentene, optically inactive, tetrabromide, m p and mixed m p 124° Dehydrogenation of the hydrocarbon with platinum on charcoal at 240° gave *p*-cymene in high yield but *m*-isopropyltoluene could not be detected, thus showing the absence of *m*-mentha-1,8-diene

F 7 *p*-Isopropenyltoluene With 2,4-dinitro-benzenesulphenyl chloride (ref 7) it gave 1-methyl-1-*p*-tolyl-2-(2,4-dinitrobenzenesulphenyl) ethylene as orange red needles, m p 115–117° (from ethanol) undepressed when mixed with the derivative of the authentic hydrocarbon (Found C, 58 2, H, 4 2 $C_{16}H_{14}N_2O_4S$ requires C, 58 2, H, 4 3 per cent)

Preparation of modified cigarettes British cigarettes (type I) containing flue-cured tobacco were continuously extracted with petrol (b p 60°–80°) to give type II cigarettes, evaporation of the petrol left a residue of 0.036 g/cigarette Further continuous extraction of type II cigarettes with methanol gave type III cigarettes, evaporation of the methanol yielded a residue of 0.36 g/cigarette Partition of this residue between water and chloroform yielded part *A* (0.31 g/cigarette) from the aqueous phase and part *B* (0.05 g/cigarette) from the chloroform phase To type III cigarettes 0.31 g/cigarette of *A* was added to give type IV cigarettes and addition of 0.05 g/cigarette of *B* to type III cigarettes gave type V cigarettes All five types of cigarette were re-humidified before use

We thank Dr J W Cook for his interest and encouragement in this investigation

COMPARATIVE INVESTIGATIONS OF THE EURYHALINE CHARACTER OF *LITTORINA* AND THE POSSIBLE RELATIONSHIP TO INTERTIDAL ZONATION

By Dr P A MAYES

Royal Veterinary College, London, N.W 1

THE zonation of plants and animals in the intertidal region of the rocky shore is strikingly similar throughout the world[1] The factors determining zonation must be closely connected with the variation in tidal level[2,3], and it is reasonable to assume that species farthest up the shore and washed less by the sea have to withstand the greatest fluctuations in environmental conditions[4] The littoral flora and fauna are adapted both physiologically and anatomically to withstand this changing environment A more detailed investigation of the physiological characteristics of the intertidal species might indicate which of the many environmental factors are likely to influence their zonation

The euryhaline character of the Littorinidae has been noted previously[5–8] and the changes in weight of the British species in dilute sea-water and their relative ability to withstand various dilutions has been described in a previous communication[4] *L neritoides*, which inhabits the splash zone[6,10] where there is maximum fluctuation in environmental conditions, showed the greatest ability to withstand and adapt to change in salinity, whereas *L littoralis*, which is confined to the fronds of the seaweeds of the middle shore, showed the least tolerance to variations in salinity None of the species survived dilution of sea-water to 25 per cent of normal, demonstrating that an osmo-regulatory mechanism is not present in the Littorinids studied The present experiments were carried out to ascertain whether this group has developed a mechanism of salt loss or gain which would help to explain their euryhaline character Specimens were transferred from normal sea-water into sea-water of either decreased or increased salinity and after a suitable period of time they were transferred back into normal sea-water If there was neither loss nor gain in salt, their weight, which would increase in the hypotonic or decrease in the hypertonic medium, would return to its original value when the animals were replaced in normal sea-water As specimens in normal sea-water lose weight slowly, due presumably to absence of food, expenditure of energy and loss of fæces, the final weight attained after replacement in normal sea-water would be somewhat less than the original weight.

Littorinids were divided into batches of seven average-size specimens of the same species and were equilibrated in normal sea-water (salinity 35.5 gm /l) for 24 hr They were transferred into 50 per cent (v/v) sea-water or 200 per cent sea-water (normal sea-water plus 35.5 gm sodium chloride/l) and after several days were returned to normal sea-water. Each batch of specimens was weighed throughout the experimental run, allowing the animals to drain, drying the outside, and after retraction, absorbing excess fluid inside the shell with filter paper. The solutions were replaced every 12 hr with freshly aerated ones The live non-calcareous weight was calculated by subtracting the weight of the shell from the original weighings Results (Fig 1) are expressed as a percentage of the live weight at the end of the period of 24 hr equilibration in normal sea-water

On immersion in 50 per cent sea-water *L neritoides*, in contrast to the other species, remained loosely retracted within its shell Ultimately, it did emerge and show locomotion in this solution, but the time required for this adaptation was quite variable The other species were active, increased in weight and showed evidence of swelling of the tissues The tendency of the species to gain weight in this hypotonic sea-water was in the following order of increasing magnitude *L neritoides*, *L saxatilis*, *L littorea*, *L littoralis* (Fig 1) When immersed in 200 per cent sea-water all specimens retracted into their shells and lost weight Again, *L neritoides* showed the least change in weight and ultimately emerged from its shell in this medium

On transference back into normal sea-water, all species dropped weight if they had been in 50 per cent sea-water and gained weight if they had been in 200 per cent sea-water, but only *L saxatilis*, *L littorea* and *L littoralis* returned to a value which was slightly less than the original, irrespective of whether they had been in hypotonic or hypertonic solutions

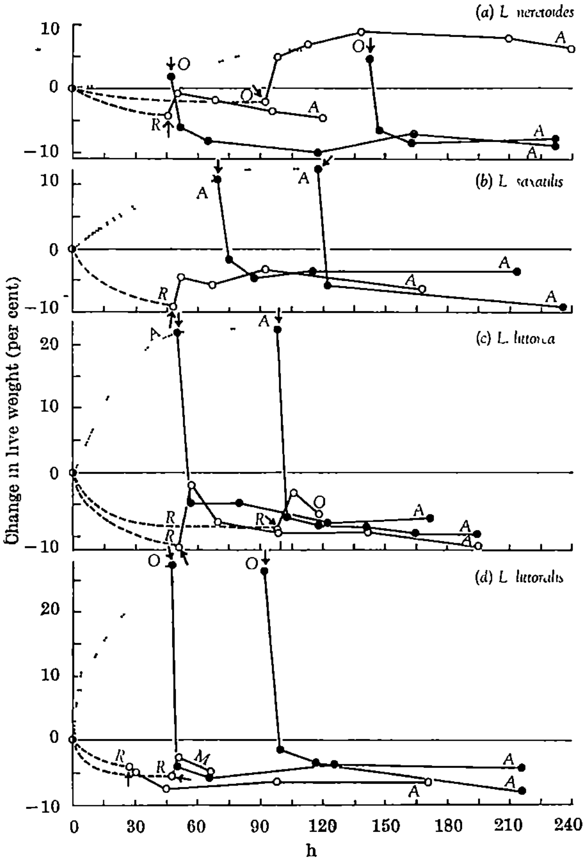

Fig 1 Changes in weight of *Littorina* when immersed in 50 per cent ( ) sea-water or 200 per cent (- - -) sea-water (after equilibration in normal sea-water for 24 hr) and the subsequent effect of transfer back into normal sea-water The arrows show when transference back into normal sea-water was made The shape of the curves in 50 per cent sea-water has been taken from a previous publication (ref 4) Each point is the mean of seven animals Live weight = total weight minus shell weight *A*, animals showing active locomotion, O, operculum open but animals partly retracted into shell, *R*, animals fully retracted into shell, *M*, moribund specimens

This is good evidence that no appreciable salt loss or gain occurs in these particular species On the other hand, *L neritoides*, when transferred from 50 per cent sea-water back into normal sea-water, showed a marked drop in weight below the original level, and when transferred from 200 per cent sea-water showed a marked increase in weight, well above the original This indicates that the small gain in weight which occurs when *L neritoides* is transferred into 50 per cent sea-water is due to loss of salt and a reduced uptake of water, and that the small loss in weight in 200 per cent sea-water is due to uptake of salts and a reduced loss of water When *L neritoides* was removed after 46 hr in 200 per cent sea-water, before the operculum had opened, and replaced in normal sea-water (Fig 1*a*), the small increase in weight was probably due to the protective effect of the operculum which in this species is most efficacious in excluding and controlling equilibration with the external medium The goodness of fit of the operculum of all four species in descending order of efficiency is: *L neritoides*, *L littorea*, *L saxatilis*, *L. littoralis*, which correlates with the time of survival in 25 per cent sea-water[4]

The euryhaline character of the Littorinidae is limited by the absence of an osmo-regulatory mechanism Within this limitation *L neritoides* appears to be better equipped for dealing with extremes in salinity than the other species because it is capable of loss or gain in salt which prevents excess swelling or shrinking of the tissues in hypotonic or hypertonic media respectively Whether this occurs as a result of the activity of a particular organ or is due to a permeability to salts of the general surface is not known The relative ability of the other species to withstand changes in salinity appears to depend on their respective capacities for tolerating hydration or dehydration and the consequent swelling or shrinking of their tissues

L neritoides and *L saxatilis* are sharply cut off at their upper limits of distribution, the former reaching a foot or so higher than the latter Colman[9] has posed the question as to what environmental factors determine such upper limits so finely The work recorded here does not seek to answer this question directly but demonstrates, in conjunction with previous work[4], the existence of physiological differences within the Littorinidae which could determine their zonation provided the appropriate conditions of salinity variation were operating in their environment

RELATIONSHIPS BETWEEN THE GENETIC EFFECTS OF DEFICIENCIES FOR CHROMOSOMES, III AND V ON MEIOTIC PAIRING IN *TRITICUM AESTIVUM*

By C. KEMPANNA and RALPH RILEY

Plant Breeding Institute, Cambridge

THE chromosomes of the hexaploid common wheat of agriculture, *Triticum aestivum* ($2n = 6x = 42$), normally make 21 bivalents at meiosis, although it has been shown that euploid plants of standard varieties usually have about 5 per cent of pollen mother cells in which one or other bivalent is not formed[1]. However, apart from these slight deviations in some euploid cells, deficiencies for two different chromosomes cause pronounced disturbance of meiotic regularity

Nullisomic plants, with 40 chromosomes, deficient for the chromosome III pair, have considerable pairing failure at first metaphase of meiosis (Table 1)[2]. 0–19 of the 20 potential bivalents are not formed (Table 2), although most commonly only one or two bivalents fail. The chromosomes which do not participate in bivalent formation are left as univalents.

Table 1. MEAN PAIRING AT FIRST METAPHASE OF MEIOSIS IN *T. aestivum* EUPLOID, NULLISOMIC-III AND NULLISOMIC-V

Plant	Chrom No	Cell No	Univ	Biv	Triv	Quad	Chiasmata per cell
Euploid	42	30	0·20	20·90	—	—	43·60 ± 0·40
Nullisomic-V	40	23	0·26	18·91	0·35	0·22	37·65 ± 0·48
Nullisomic-III	40	30	8·56	15·72	—	—	23·90 ± 1·51
Nullisomic-III	40	30	5·00	17·50	—	—	27·60 ± 0·97

Chromosome III, therefore, carries one or more genes which are responsible for the maintenance of the normal bivalent pattern, and Sears[3] has shown that the relevant genetic activity is restricted to one arm of the chromosome. The modification of the sequence of meiosis in the absence of chromosome III could result either from the failure of homologous chromosomes to synapse (asynapsis) or from the failure of chiasma-formation after normal synapsis (desynapsis). The difficulties of making adequate prophase preparations, in wheat, preclude the formation of a firm choice between the two alternatives. Nevertheless, from the examination of prophase in nullisomic-III plants, in the present work, it appears likely that the abnormality is desynaptic in origin, since no failure of pairing was detected. The conclusion may be tentatively advanced, therefore, that the activity of chromosome III is responsible for the completion of regular chiasma-formation in wheat.

One or more genes on the long arm of chromosome V are responsible for the restriction of meiotic pairing to the formation of bivalents[4,5]. In the absence of this chromosome, from nullisomics and from haploids or hybrids, homoeologous chromosomes from the three component sub-genomes can pair and multivalents are common (Table 1). The meiotic affinity between corresponding chromosomes of the different sub-genomes is therefore normally suppressed by the activity of chromosome V in euploid individuals of wheat.

The evidence so far available suggests that the restriction of pairing to complete homologues, exercised by this chromosome, does not result from any alteration in the frequency or distribution of chiasmata. Consequently the mechanism probably functions through modifications of the processes which initiate synapsis and it may be said to enhance genetically the affinity of homologues relative to homoeologues.

In view of the relaxation of the genetic control of apparently different aspects of the meiotic process, which results from the absence of chromosomes III and V, it is of some interest to determine the outcome of the simultaneous deficiency for both. Material for this purpose has been developed in the present work in the variety Chinese Spring.

Plants with 41 chromosomes, monosomic for chromosome V, were pollinated with pollen from 40-chromosome plants nullisomic for chromosome III. Plants with 40 chromosomes were selected in the F_1 generation—these were the segregants to which chromosome V of the monosomic parent had not been transmitted. At meiosis the 40-chromosome F_1 plants had 19 bivalents and two univalents and they were, therefore, monosomic for chromosome III and chromosome V. No attempt was made to obtain the doubly nullisomic segregants in the F_2 generation because of the known low rate of transmission through the pollen of deficiency for chromosome V. Instead, the doubly monosomic F_1 individuals were pollinated with pollen from the perennial rye species, *Secale montanum* ($2n = 14$).

Potentially, plants with 26, 27 and 28 chromosomes were possible in the progeny of this cross, depending on the transmission of the two univalents. Those with 28 chromosomes would carry both III and V, and those with 26 chromosomes neither III nor V. The 27-chromosome plants could be deficient for either chromosome III or V, but not both. Among the eight *T. aestivum* × *S. montanum* hybrids grown one had 28, three had 27 and four had 26 chromosomes.

Meiosis was studied in pollen mother cells in Feulgen–orcein squashes of the hybrids, and the mean pairing at first metaphase is shown in Table 3. Hybrid 1—a euploid with 28 chromosomes—had a mean bivalent frequency of 1·08, and the range in bivalent frequency was 0–3 per cell. There were no multivalents. This pattern of behaviour coincides well with that commonly reported for euploid wheat-rye hybrids[6].

The three 27-chromosome hybrids fell into two categories. Hybrid 2 had a high level of pairing with a mean of only 12·40 univalents per cell, bivalents and trivalents were common and there were occasional quadrivalents. As many as 20 chromosomes were associated in some cells—in one such there were seven univalents, seven bivalents and two trivalents. The cell with the least pairing had two bivalents and a trivalent. This is the pattern of homoeologous pairing to be expected when chromosome V is deficient and it has been shown that the deficiency of no other wheat chromosome can produce a similar increase over the level in a eulpoid hybrid[7].

By contrast, in the other two 27-chromosome plants, hybrids 3 and 4, only one cell was recorded with any pairing and this merely had one bivalent. Apparently chromosome III was deficient from these hybrids, and it is clear, by comparison with the euploid hybrid, that the absence of this chromosome had led to some bivalent failure like that which occurs in nullisomic-III wheat plants. It should be indicated that, although Riley, Chapman and Kimber[7] recorded

Table 2. FREQUENCY OF CELLS WITH VARIOUS NUMBERS OF BIVALENTS AT FIRST METAPHASE OF MEIOSIS IN *T. aestivum* NULLISOMIC-III

8	absent	absent	26	50	16·70	4·08	0·38	—	6·00 ± 0·39	4

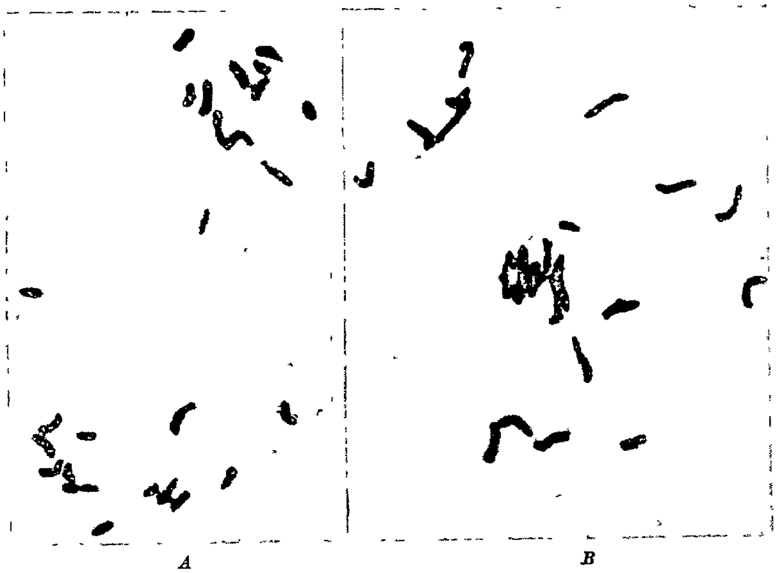

Fig. 1. First metaphase of meiosis in Feulgen and orcein stained squashes of pollen mother cells in a 26-chromosome hybrid from the cross *T. aestivum* Chinese Spring monosomic-III and -V ($2n=42-2$) × *S. montanum* ($2n=14$) (× 700). *A*, 26 univalents, arranged in two polar groups with one at the equator; *B*, 5 bivalents and 16 univalents.

a low level of pairing in *T. aestivum* × *S. cereale* hybrids deficient for chromosome III, the reduction of pairing was not so pronounced as in the present material. The difference in behaviour may relate to the use of a different rye species as a parent, or may merely be environmental determined.

It is clear that there were marked differences between the euploid and the two types of 27-chromosome hybrids. Moreover, the data for all three were different from those for the 26-chromosome plants simultaneously deficient for both chromosomes. Although there was high pairing in these (Fig. 1*B*) with bivalents, trivalents and quadrivalents—as in the *V*-deficient hybrid—the mean pairing was considerably lower (Table 3). This showed most clearly in the higher mean frequency of univalents and the low mean chiasma-frequency per cell. Thus the relaxation of the regulation normally exercised by both chromosome III and V over the course of meiosis might have been apparent in all cells.

However, the 26-chromosome hybrids displayed a pattern of pairing not shown by those with higher chromosome numbers. In all the doubly deficient plants there was a number of cells, which ranged from 8 to 28 per cent of the total, with no chromosomes paired (Figs. 1*A* and 2). This discontinuity in the distribution of cells with various numbers of chromosomes paired did not occur in the V-deficient hybrid, which the pairing of the III- and V-deficient hybrids otherwise most nearly resembled. If the cells with no pairing are excluded and the mean pairing recalculated for the remainder, the resulting means are much closer to those of the 27-chromosome, V-deficient, hybrid (Table 4). Slight differences remain, however, in that there was a higher univalent frequency and a smaller number of multivalents.

Table 4. MEAN PAIRING AT FIRST METAPHASE OF MEIOSIS IN *T. aestivum* × *S. montanum* HYBRIDS DEFICIENT FOR CHROMOSOMES III AND V OF *T. aestivum*, EXCLUDING THOSE CELLS WITH ONLY UNIVALENTS

Hybrid	Chrom. No.	Cells	Univ.	Biv.	Triv.	Quad.	Chiasmata per cell
5	26	36	13·61	5·08	0·66	0·06	8·36 ± 0·32
6	26	42	12·40	5·67	0·69	0·05	9·50 ± 0·29
7	26	44	14·86	4·85	0·47	—	7·14 ± 0·32
8	26	46	15·89	4·43	0·41	—	6·52 ± 0·32

The bimodality of the distribution of cells with various amounts of pairing demonstrates that in different cells the effects of both deficiencies were separately apparent. Those cells in which chiasma formation occurred had a pattern of pairing characteristic of chromosome V deficiency. By contrast the cells with no pairing at first metaphase matched the behaviour of the chromosome III-deficient hybrids. It is not apparent whether the slightly lower level of pairing in those cells in which there was chiasma formation implied that an influence of the deficiency of chromosome III occurred throughout and not only in the cells completely without pairing.

If the effect of deficiency for chromosome III is to cause desynapsis, chiasma-formation must have been completely inhibited in some cells in the III- and V-deficient hybrids. There was no similar discontinuity in the distribution of cells with various amounts of bivalent failure in III-nullisomic plants (Table 2). This suggests that the causal factors determining the failure of pairing, which result from the absence of chromosome III, were much closer to a threshold

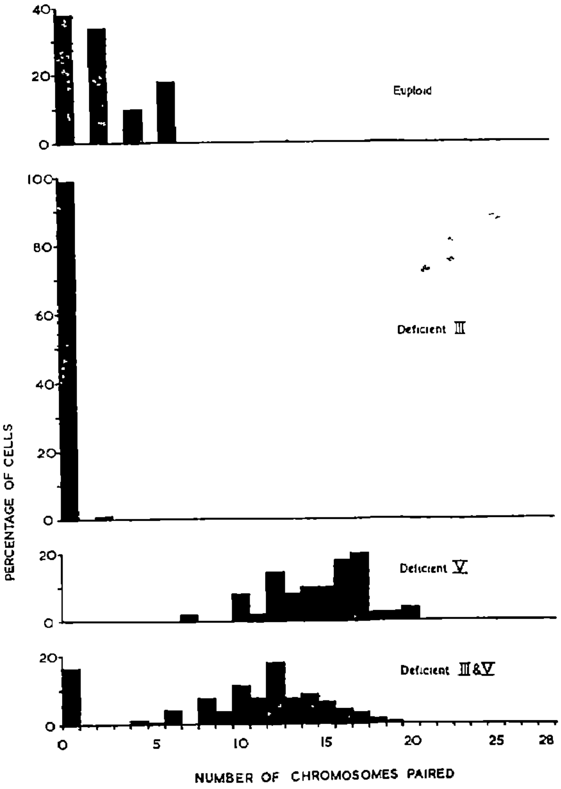

Fig. 2. A histogram showing the frequency distribution of cells with various numbers of chromosomes paired at first metaphase of meiosis in hybrids derived from the cross *T. aestivum* Chinese Spring monosomic-III and -V ($2n=42-2$) × *S. montanum* ($2n=14$). Euploid = 28-chromosome hybrid, chromosomes III and V present. Deficient III = 27-chromosome hybrids, chromosome III absent. Deficient V = 27-chromosome hybrid, chromosome V absent. Deficient III and V = 26-chromosome hybrids, chromosomes III and V absent.

value when chromosome V was simultaneously absent. Moreover, the modifications which followed an apparent switch of the determinants from one side of the threshold to the other were quite abrupt. Either the pairing was very little different from that in the simple V-deficient hybrid, or there was no pairing whatsoever. Further information on the nature of the differences between the two distinct meiotic patterns may well result from future work on environmental influences.

The choice between the possibilities of a desynaptic or an asynaptic effect of deficiency for chromosome III is not aided by the present results. If the effect were asynaptic the behaviour of the 26-chromosome hybrids would be ascribed to the complete absence of prophase pairing in some cells, if desynaptic to the complete absence of chiasma-formation in some cells. Nevertheless, there must be a functional relationship between the disturbances of the meiotic process caused by deficiencies of chromosomes III and V since only when V is deficient is there an abrupt discontinuing in the pattern of pairing. This leads to speculation concerning the possible evolutionary relationships of the systems controlled by the two chromosomes.

Modification of a function of chromosome V by mutation subsequent to its incorporation in wheat has been responsible for the diploid-like meiotic behaviour and disomic inheritance of the polyploid species[8]. It may be that the genetic influence of chromosome III, in maintaining bivalent formation, has also arisen as a result of a change in function, and that this change was in some way complementary to that on chromosome V. Both chromosomes were derived from the same diploid species, *Aegilops speltoides* ($2n = 14$), in the evolution of polyploid wheat, but although it has been possible to obtain evidence on the function of chromosome V in its original state this has not yet been done for chromosome III. Experiments with this object have now been commenced.

EFFECT OF FEEDING X-RAY IRRADIATED COLIFORM BACILLI TO TUMOUR-BEARING MICE

By Dr. ARTHUR COMPTON
Wright-Fleming Institute, St. Mary's Hospital, London, W.2

THIS article follows earlier work[1] on the feeding to tumour-bearing mice of homologous and heterologous tissues, or tissue extracts, which had been irradiated with X-rays, with the view of testing the effect, if any, of such irradiated material on tumour growth[2]. The present communication is the record of two initial experiments, utilizing bacteria instead of animal tissues, to fix the supposedly beneficial radiation.

Experiment 1. 10 silver-grey mice, to all intents of an inbred strain, were grafted subcutaneously in the right groin with tumour Compton 22, a progressively growing adeno-carcinoma, which arose spontaneously some five years ago in a white female mouse of our laboratory stock[1]. Characteristic features of this tumour are that grafts grow to enormous dimensions, frequently without ulceration, and, when the latter does occur, it remains superficial, with a noteworthy absence of suppuration. The grafting was done with a wide-bore needle and a 1-ml. Record syringe, each mouse receiving approximately the same-sized, unusually large, implant—to ensure good tumour 'takes' and vigorous follow-up growths—of an average weight 24 mg, lodged carefully in the barrel of the needle prior to being injected by the syringe. The tumour is now in its seventy-fifth generation of transplantation.

Immediately after grafting, the 10 mice were separated at random into two lots of 5 mice each, in two separate mouse cages. One lot (treated series) was fed daily, during 16 days—the equivalent of some 10 months in the human being—with 15 ml. of an equal parts mixture of 24-h broth cultures of three different coliform bacilli, which, after mixing, were irradiated in an open Petri dish of 4 in. diameter for 1–2 min at a distance of 20 cm from the X-ray anode, the apparatus being otherwise run at 30 m.amp. and 50 kV (that is, a radiation dose of 15,000–30,000 r.). After the irradiation, the mixture was transferred to a 4-oz. feeding bottle with a further 20 ml. of tap-water, making 35 ml. in all, and the bottle stoppered with a rubber teat perforated by a short length of glass tubing, inverted and placed in position on the roof of the mouse cage. During the 16 days' feeding this was interrupted on two separate days as rest-periods, when tap-water alone was given. The other lot of 5 mice were kept as controls, receiving tap-water for drinking. Both lots were fed with the same solid food throughout, small fragments of commercial sticks of 'Diet 41' (Ranks).

Experiment 2. Nine silver-grey mice—5 of medium size and average weight 32–33 g, and 4 larger of 40 g average weight—were grafted subcutaneously into the right flank with tumour 22 Compton—now in its eighty-third generation of transplantation—using a wide-bore needle as before. The point of the needle was introduced into the right groin and pushed along a pinched-up fold of skin towards the axilla. Immediately after grafting, the lot of medium-sized mice (Nos. 1–5) was fed daily during 28 days—equivalent to about 1·5 years in the life of a human being—with 10 ml. of an irradiated 24-h nutrient-broth culture of *B. coli communior Alex II*, 825 *B*(2) (ref. 3), the remaining mice (Nos. 6–9) being kept as non-treated controls. The fact that the 4 control mice were initially larger, heavier animals than the 5 treated is viewed in no way as detracting from the experiment. It may be viewed even as all to the good, since graft tumours are known to grow as a rule better in older, larger animals[4].

The irradiation dosage used was as follows. During the first 12 days the broth culture was irradiated daily in an open Petri dish for 1 min at 20 cm from

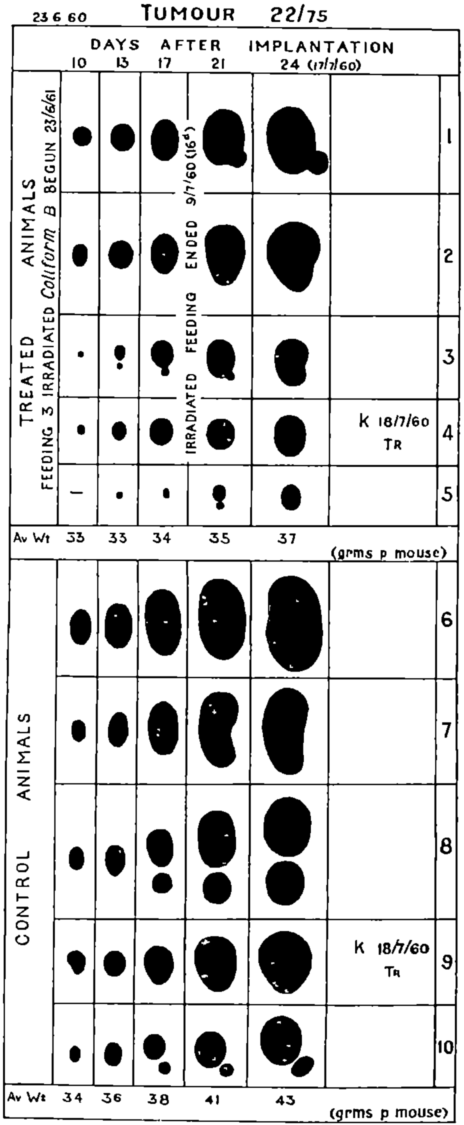

Fig 1

the anode, the apparatus otherwise being run as before at 30 m amp and 50 kV (15,000 r), then, during the subsequent 15 days, for 1 5–2 min at 15–20 cm (22,000–50,000 r)

The steps after the irradiation were about as before the 10 ml of irradiated liquid from the Petri dish, on transference to the feeding bottle, were diluted to 30–35 ml with tap-water

In brief summary, experiments 1 and 2 present the following contrasts (1) three coliforms were used in experiment 1, of which only one was used in the repeat experiment 2, (2) the daily irradiation dosage was about the same in both 15,000–30,000 r in experiment 1, and 15,000–50,000 r in experiment 2, (3) the irradiated coliform feeding was kept up for 16 days in experiment 1 and 27 days in experiment 2

The results of the two experiments are given graphically in Figs 1 and 3, where tumour growths are recorded in terms of (1) individual tumour silhouettes, as measured by calipers at various charting times, and (2) collective average weights of the animals, weighed at these charting times

Consider Fig 1, which records the results of experiment 1 The tumour silhouettes here indicate very different rates of tumour growth in the treated (Nos 1–5) and in the control (Nos 6–10) animals In the latter all 5 implants (100 per cent) show homogeneously progressive tumour growths But not so in the treated, where 3 tumours out of 5 (60 per cent) show early, comparative inhibition of tumour growth, with subsequent comparatively slower development

The defect of silhouette representation, as an evaluation criterion of tumour growth, is that it fails to reveal tumour dimensions in depth It reveals dimensions in one plane only, so that, on such representation, a tumour may occasionally be larger than it seems, and vice versa On the other hand, average body weights, the other evaluation criterion, are seen to parallel so closely the silhouette appearances that it is evident the latter can be relied on as providing fairly accurate measures of tumour progress, in spite of their limitation

But collective mean body weights, as measures of tumour development, are so instructive that they merit a brief consideration on their own At the start of the experiment (June 23, 1960) they were roughly identical in both the treated and control series, considering the 'at random' basis on which the animals, uniformly sized and healthy, were separated By the tenth day they are seen to have begun to diverge slightly, to go on diverging still more afterwards By the seventeenth day, the collective average weight of the control animals is 38 g per mouse, as against 34 g per mouse for the treated animals At the twenty-first day there is a maximum divergence of 6 g more per mouse in the controls than in the treated, which difference is still maintained at the next charting 3 days later

By plotting collective average body weights against the day of tumour growth for the treated and control animals, we get the two curves of Fig 2 Here the initial slowing of tumour growth, as reflected in body weights for the treated animals, and characterized by the initial flattening of their growth curve, is noteworthy, being in marked contrast with the steadier, upward slope of the curve for the control series

It thus becomes evident that these curves, in their contrasting shapes, provide not only factual evidence,

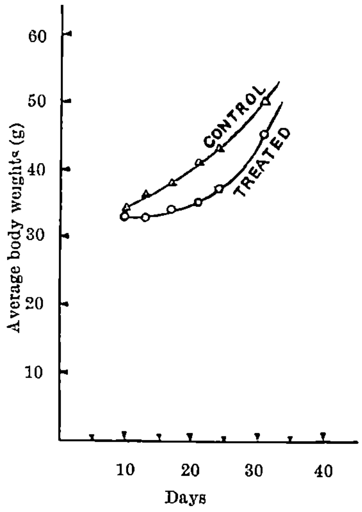

Fig 2

but also some measure, of the inhibiting influence on tumour growth of the treatment Actually, as previously pointed out[2], theoretical considerations confirm that there should occur, for the treated animals, unless the treatment is 100 per cent effective with no tumour growth occurring, such initial delay or lag in the time growth curve before it finally turns abruptly upwards

The slow rate of weight increase in the treated animals might be thought of as due perhaps to their drinking less and eating less—though proof of this is lacking If this were the explanation, one would expect the situation to change dramatically with the cessation of the treatment on the sixteenth day, to result in a very definite, sudden weight increase soon thereafter But no immediate increase of weight is seen to occur In fact, the rate of increase of weight, on suspension of the treatment, continues at the same initial rate throughout the following week, with no pronounced increase being noted until well beyond the twenty-fifth day, when the curve commences to rise rapidly to the normal ending characteristic of tumour growth in general Hence, from this *reductio ad absurdum* type of argument, it is reasonable to conclude that the early loss of weight and lessened tumour growth cannot be due to the animals merely drinking and eating less *per se*, but rather to the effect of the irradiation on the drink they received

Now, body weights are a function of (1) the rate of tumour growth, of which tumour silhouettes, as already stressed, give an only on the surface presentation; (2) the fitness, or otherwise, of the mice, in which connexion it is to be noted that the animals here appeared equally lively and fit throughout in both experiments, with no deaths in either It can, then, be assumed that the differences in body weights are not due to any lack of fitness of the treated mice in either series, but are, in the main, a simple expression of the more vigorous tumour growths in the control than in the treated animals—thus confirming the silhouette findings

Both criteria, silhouettes and body weights, are, then, mutually demonstrative of the restraint on tumour growth exerted on the treated animals by their feeding with the irradiated coliforms. It is to be remarked, in passing, that in this respect not every coliform is effective; 9 others were tested, but proved ineffective It may well be that only one of the three here used was the active radiation carrier

Why the tumours of mice 1 and 2, in the treated series (Fig 1), do not appear to have been favourably affected by the treatment cannot for the moment be explained, unless it be that these mice (1) for a day or so at the start of the treatment may have refused the irradiated feeding mixture, at a time when the grafts would normally be being established, when new blood vessels would be being formed, linking the graft in its new surroundings to the blood supply of the host, or (2) may fall into the category of one of the paradoxes of cancer, namely, that agents which at times seem to cure, at others seem to foster growth, to be in fact potential carcinogens X-rays are the classical example of this.

Fig 1 further records that two tumours, one in the treated series and one in the control series, those of mice 4 and 9, the former seemingly rather slow growing, were transplanted when 25 days old (July 18, 1960) each into 10 normal mice Both transplanted tumours gave rise to normal types of progressively growing tumours The slower-growing tumour in mouse 4 was thus seen to have reverted, on transplantation into normal animals, to its customary, rapidly progressive, growth behaviour. So then, however its growth may have been restrained and checked when undergoing treatment in the parent animal, no permanent, hereditary change had obviously thereby been imposed on it

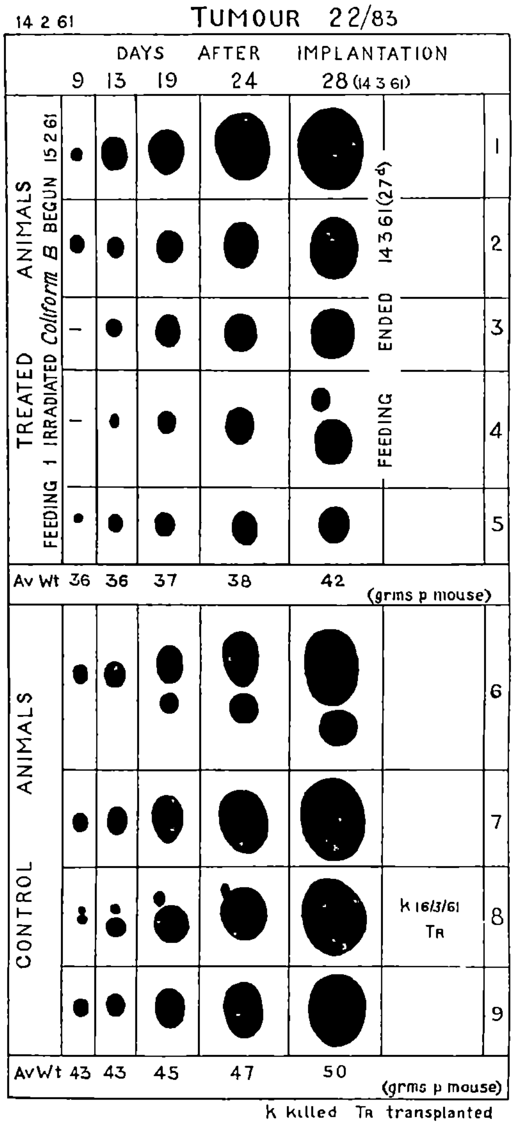

Fig 3

Turning now to Fig. 3, which records the result of experiment 2, the overall picture here is remarkably like that of the previous experiment · good, vigorous, progressively growing tumours in all (100 per cent) of the control mice (Nos 6–9), with restrained, clearly 'held-up', initial growths in 3, even 4, out of 5 (60–80 per cent) of the treated animals (Nos. 1–5) The treatment here was limited to feeding with only one type of irradiated coliform bacillus

Experiment 2 confirms experiment 1 in providing results which are, to all intents and purposes, replicas the one of the other, both showing · (*a*) a like initial 'hold-up' of tumour growth in about 60 per cent of the treated mice; and (*b*) a like 100 per cent of steadily progressive tumour growths in the controls

Such results call for prudence in their interpretation, pending repetition on a larger scale Some may be inclined to dismiss them as due to chance, others not That they are unlikely to be due to chance follows, I think, from the following, among other, considerations, which appear to me to justify publication now, in order that others can have an opportunity to take part in such further repeat work:

(1) That the mice used (a strain of silver-grey) were specially susceptible to graft cancer, the controls showing no resistance whatever

(2) That specially large tumour implants were purposely used, to enhance to the full the occurrence of good tumour-taking throughout

(3) That the mice destined for treatment and for controls were in no way selected, but were separated 'at random' after the transplantation in each experiment

(4) That the number of mice to be fed with irradiated bacteria was limited in both experiments, so that the quantity of material to be daily irradiated for the feeding might be handled with ease, and thus be satisfactorily dealt with, without haste

(5) That on the two occasions (Figs 1 and 3) when the work was done with irradiated effective, in contradistinction to irradiated non-effective, coliform bacilli, the same kind of result invariably occurred initial inhibition of tumour growth among a certain proportion of the treated animals, with good, steadily progressive, tumour growth among all the control animals

The preliminary findings thus recorded, with only a small number of animals in each experiment, can be viewed as capable of being improved on, as follows

(1) To discover other bacteria still more elective as fixers of the beneficent irradiation

(2) To perfect still further the irradiation dosage

(3) To try out other routes of administration than by the alimentary tract

(4) To isolate the hypothetical, active, inhibitory substance in a pure state, and thereby to make way for a study of its chemical constitution and possible synthesis

All four, in the hope of restraining still more effectively, even possibly reversing, cancer growth

I thank Prof C A Pannett, whose own work inspired the investigation, the Principal of the Wright-Fleming Institute, St Mary's Hospital Medical School, London, W 2, for facilities to conduct the research, and the Frederick F A Pearson Foundation, U S A , for financial support

SELECTION FOR DIGESTIBILITY IN HERBAGE GRASSES

By Dr. J P. COOPER

Welsh Plant Breeding Station, Aberystwyth

AND

Dr J M A. TILLEY, W F RAYMOND and R A TERRY

Grassland Research Institute, Hurley

THE primary factor governing the nutritive value of herbage is its digestibility, which not only determines the proportion of the feed which can be utilized by the animal, but also greatly influences the amount eaten[1-3] The development of herbage varieties of high digestibility is thus an important objective for the plant breeder

It has long been known that the leaf blade is lower in fibre and higher in protein content than the stem[4], and as these fractions have been assumed to be closely correlated with digestibility, herbage breeding programmes have emphasized breeding for leafiness However, Minson *et al* [5] have shown that there is frequently only a small correlation between herbage digestibility and leaf/stem ratio, and that leafy cuts of different herbage species may also differ markedly in digestibility perennial ryegrass, for example, has consistently been more digestible than cocksfoot at the same stage of growth This demonstration of differences in digestibility between species suggested that it might be profitable to look for genetic variation within a species, which could then be used in a selection programme

The standard estimation of digestibility by feeding trials with sheep cannot, however, be used to screen breeding material at the individual genotype level, because of the large quantities of herbage required An *in vitro* laboratory method for estimating herbage digestibility, developed by Tilley *et al* [6], requires only small amounts of herbage (In this method 0 5 g of dried milled herbage is first digested for 48 h with strained rumen liquor at *p*H 6 5–7 0, and the residue further treated for 48 h with acid pepsin to remove digestible protein *In vitro* digestibility is calculated from the weight of 'indigestible' residue) Estimates of digestibility so obtained show a high correlation ($r = 0\ 95$) with the corresponding *in vivo* results, and the method appeared promising for the investigation of the digestibility of small samples of breeding material

Preliminary analyses of individual genotypes and families of ryegrass (*L perenne*) and cocksfoot (*D glomerata*) have given encouraging results The ryegrass genotypes, all from the variety *S* 23, were harvested in April 1961, the cocksfoot genotypes included material from Brage, *S* 37, *S* 143 and *S* 341, and were harvested in the aftermath in September 1961 All plants were completely vegetative Families derived from certain of these genotypes were sown in boxes in May 1961 and two primary harvests were taken one in July and the second in August, again only vegetative material being used (*N B* The cocksfoot families were sampled for analysis before the cocksfoot genotypes)

As shown in Table 1, considerable differences in the percentage digestibility of the dry matter were found between the individual genotypes Even within the single ryegrass variety (*S* 23) a range of 63–84 per cent was recorded, although most plants were more than 78 per cent, the cocksfoot digestibilities ranged from 53 to 68 per cent The lower digestibility levels of the cocksfoot may have been due in

Table 1 Genotype and Family Differences in Digestibility

Original populations	Mean	Range	No of single plants (genotypes)
Perennial ryegrass (*S* 23)	79 5	63 3–83 5	30
Cocksfoot*	60 7	52 5–67 5	35

Families	July cut			August cut			
	Mean	Range	*LSD* 5 per cent	Mean	Range	*LSD* 5 per cent	No of families
Perennial ryegrass (*S* 23)	82 4	79 9–85 9	3 2	76 0	70 7–79 9	3 6	15
Cocksfoot*	76 3	73 2–79 6	3 2	65 5	60 3–70 0	3 6	18

(*Includes Brage, *S* 37, *S* 143, *S* 341)

Table 2 Repeatability and Heritability Estimates

Repeatability	July × August cut
Perennial ryegrass	*r* = 0 44
Cocksfoot	*r* = 0 53

Heritability	July cut	August cut
Perennial ryegrass	− 0 29^{ns}	+ 0 17^{ns}
Cocksfoot	+ 0 52	+ 0 53

part to inherent differences in digestibility and in part to the different dates of harvesting[5]

Significant variation in digestibility was also found between the families within each species, in this case the ryegrass and cocksfoot were more comparable, having been cut on the same dates and at similar stages of growth The differences within each species were greater at the second cut, the extreme families differing by about 10 units of digestibility The cocksfoot families were all less digestible than the ryegrass, although the most digestible cocksfoot family almost reached the lower end of the ryegrass range

In order to assess the possibilities of selection for high digestibility, a knowledge of the repeatability and the heritability of this character is necessary (Table 2) The repeatability between the two successive cuts of the families proved to be reasonably high (0 44 for ryegrass and 0 53 for cocksfoot) The heritability estimates, derived from parent–progeny correlation, gave little information in the ryegrass families, as all the parents which had been used for crossing were of high digestibility, and the mid-parent values thus showed little variation (79–83 per cent) As a result, no significant correlation with progeny means could be obtained, in spite of the differences between the families In the cocksfoot families, on the other hand, the heritability was + 0 52 for the July cut and + 0 53 for the August cut, this indicated that more than half the variation in digestibility between the cocksfoot families was of genetic origin The stability of these family differences from year to year has now been confirmed by the analysis of individual seedlings from contrasting ryegrass and cocksfoot families in April 1962 These analyses have also revealed considerable plant-to-plant variation even within 'high' and 'low' families, and have thus made it possible to continue with a second cycle of selection

These results thus suggest that genetic variation in digestibility exists within herbage species and can be utilized by the breeder Some advance under selection can be expected in species already of high digestibility, for example, ryegrass, particularly when at a fairly mature stage at or after flowering The margin for improvement appears greater, however, in species at present of lower digestibility, for example, cocksfoot, and it may be possible to bring the digestibility of such species up to the ryegrass level However, even a small improvement in overall digestibility within a herbage species would be of practical value, because of the much greater resulting potential of that species for animal production[3]

The development of a laboratory technique for the analysis of digestibility at the individual genotype level has thus made possible the rapid screening of breeding material, and the selection of desirable genotypes which may allow the breeding of herbage varieties of improved nutritive value

SOWING WINTER WHEAT ON LEYS DESTROYED WITH A HERBICIDE

By R. A. ARNOTT and C R. CLEMENT

Grassland Research Institute, Hurley

A PRELIMINARY investigation of the use of herbicides, instead of ploughing to kill the grass sward before growing wheat, was stimulated as a result of the success of sod-seeding herbage crops in New Zealand[1,2], in the United States[3], and in the United Kingdom[4,5] Investigations reported by Clement and Williams[6] showed that after 3 or 4 years under leys, the increase in soil organic matter and crumb stability is largely confined to the top 2 cm of soil This finding suggested the need to investigate the possibility of growing wheat after leys without disturbing the soil more than is required to sow the seed the effect of the compactness of soils under leys on the growth and yield of wheat could also be examined Another question arises concerning the release of nitrogen in the soil after the sward is destroyed by herbicides compared with that in soil ploughed and cultivated unpublished results of soil analyses from our previous experiments suggest that the mineralization of organic nitrogen occurs more slowly after destruction by herbicides

In the autumn of 1960, an experiment was started to compare the following treatments on a 4-year-old ryegrass/white clover ley (1) Ploughing and seed bed preparation in the normal way (2) Applying 10 lb of amino-triazole per acre (with ammonium thiocyanate activator) (3) Skimming the grass off just below the soil surface with a flail type forage harvester

Five rows of Capelle winter wheat were sown on six occasions The first was on September 29, 1960, the day the amino-triazole was applied The wheat was hand sown in rows seven inches apart on all three treatments This was done with the minimum

Table 1 YIELDS OF WINTER WHEAT
(Dry weight of grain in g /3-yd row)

Sowing date	Treatment mean of three replicates			
	Ploughed	Sprayed	Skimmed	*S.E.*
29 9 60	183	173	72	±15 5
30 9 60	142	145	87	± 6 5
3 10 60	120	166	95	± 8 8
10 10 60	203	199	90	± 8 9
8 11 60	217	211	63	±16 5
16 11.60	165	178	24	±13 2

disturbance of the soil on the mechanically cleared and sprayed treatments No fertilizer was applied to the wheat at any time

The herbicide killed the ley slowly but completely Residual toxicity reduced the number of established wheat plants only in the first and second sowings Skimming the soil surface reduced competition from the old sward until the following spring afterwards, the grass recovered and adversely affected the wheat Although the wheat on the sprayed treatment was shorter and lighter in colour than that on the ploughed treatment during winter and spring, there was no difference at harvest in either height or appearance

Table 1 shows that wheat grown after skimming the soil surface gave significantly lower grain yields for all sowing dates than that grown on the ploughed or the sprayed treatment Grain yields on the ploughed treatment did not differ significantly from those on the herbicide (sprayed) treatment The only significant difference between these two treatments occurred after the third sowing date (October 3 1960), that is, five days after spraying, when the sprayed gave the higher grain yield This experiment has shown that it is possible to establish winter wheat after leys killed by a herbicide, and to obtain yields similar to those after ploughing and conventional seedbed preparation There was no evidence that yields on unploughed land were limited either by soil compaction or reduced mineralization of nitrogen

We thank Mr. Lewis Jones for advice and assistance with herbicidal spraying and Dr William Davies for advice and facilities

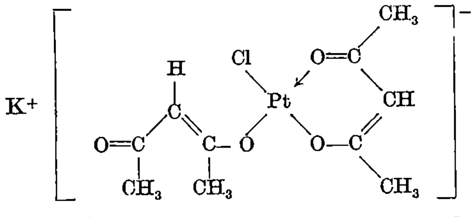
STRUCTURE OF A CARBON-BONDED ACETYLACETONE COMPLEX OF PLATINUM (II)

By Dr B N FIGGIS, Prof J LEWIS*, R. F. LONG, Dr. R. MASON, Prof R S NYHOLM, F R S, Dr P J PAULING and G B. ROBERTSON

Inorganic Crystallography Laboratory, Imperial College, S W 7, and Department of Chemistry, University College, W C 1

IN 1901, Werner described a group of compounds formed from the reaction of potassium chloroplatinite with acetylacetone[1], among these was the complex potassium *bis*acetylacetonato-chloro-platinate (II) (KPt(Acac)$_2$Cl) This compound was re-investigated by Grinberg and Chapurskii[2], who, on the basis of conductivity data, concluded that the structure (1) formulated by Werner was essentially correct The structure was based on a co-ordination number of four generally observed for platinum (II) complexes



(1)

Alternative formulations of the stereochemistry of KPt(Acac)$_2$Cl could be a five co-ordinate complex utilizing all oxygens of the acetylacetone residues and the chlorine in a way similar to the structure of *tris*-(*o*-diphenylarsinophenylarsine)iodo-platinum (II) tetraphenyl borate[3] or a four co-ordinate structure involving one of the acetylacetones bonding through the γ-carbon atom Such bonding has been previously observed in the case of some platinum (IV) complexes[4], and we can now report evidence for the existence of such bonding in complexes of platinum in the lower oxidation state

The crystals of KPt(Acac)$_2$Cl (from aqueous solution) are monoclinic a = 25 97 Å; b = 13 73 Å, c = 7 81 Å, β = 92 0° The space-group is I2/c, which is a non-standard setting of C2/c The X-ray analysis, using some 3,000 three-dimensional reflexions, was determined by Patterson and Fourier methods, the molecular geometry of the platinum ion shown in Fig 1 corresponding to the usual residual factor R = 0 10 after two cycles of least-squares refinement of atomic co-ordinates and anisotropic Debye factors

The standard deviations of the bond-lengths of Fig 1 are 0 015 Å for the Pt—Cl bond, 0 025 Å for the

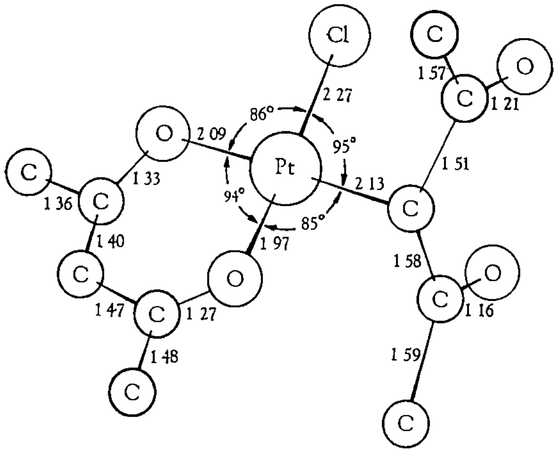


Fig 1 A view of the complex ion *bis*acetylacetonato-chloroplatinum (II) showing interatomic distances and certain angles

---

* Now in the Department of Chemistry, University of Manchester

Pt—O and Pt—C bonds and 0 10 Å for all carbon–carbon and carbon–oxygen bonds Least squares refinement of the X-ray data is continuing and we shall report more accurate values for the bond-lengths and bond-angles elsewhere

The co-ordination of the platinum is square planar with only one acetylacetone co-ordinating through its oxygens, the other bonding through the carbon atom The lengths of the platinum–oxygen bonds *cis*- and *trans*- to the chlorine may be significantly different. The chlorine is six-co-ordinated by potassium ions at distances of 3 22 Å (twice), 3 25 Å (twice) and 3 61 Å (twice) There are two crystallographically and stereochemically non-equivalent potassium ions in the molecule K_1 is six-co-ordinated by pairs of oxygen atoms at 2 73 Å, 2 76 Å and 2 89 Å while K_2 is surrounded by a pair of oxygens at 2 84 Å and two pairs of chlorines at 3 22 Å and 3 25 Å respectively All other intra- and inter-molecular distances are of the usual order

Infra-red and nuclear magnetic resonance analyses offer some evidence that the platinum ion has essentially the same structure in solution as in the crystal

(1) The infra-red spectrum of KPt(Acac)$_2$Cl in deuterium oxide shows only minor changes, due to solvent perturbation, in the carbonyl-stretching region from those in nujol In contrast to the infra-red spectra of a number of transition metal acetylacetonates[5] KPt(Acac)$_2$Cl shows the presence of some strong bands above 1,650 cm^{-1} In nujol these actually occur at 1,653 cm^{-1} and 1,695 cm^{-1} and can be assigned to the free ketonic C=O stretching modes Two distinct types of C—H's in the complex are also indicated by the infra-red data of the γ-carbon–deuterium substituted molecule

(2) The complex behaves as a uni-univalent electrolyte and the molecular weight determined cryoscopically corresponds to the monomeric formulation

(3) The H^1 nuclear magnetic resonance spectrum of the complex at 40 Mc/s shows the presence of two separate methyl absorptions of equal intensity, with chemical shifts of 1 94 and 1 46 p p m relative to dioxane The splitting of the methyl protons by coupling to the platinum (platinum-195, abundance 33 7 per cent, spin ½) was readily observable for one of the groups ($J_{Pt\text{-}H} = 5\ 6$ c p s) but not for the other ($J_{Pt\text{-}H} \sim 2\ 5$ c p s) On the basis of the structure shown in Fig 1, three groups of methyl resonance frequencies might have been anticipated since there seems no *a priori* reason for equivalence of the methyl groups of the oxygen-co-ordinated acetylacetone The chemical shift between them is not expected to be large, however, and the fact that they give rise to but one group in the nuclear magnetic resonance spectrum must be due to a chemical shift below the limit of resolution The signals from the γ-carbon–protons were not of sufficient intensity to be interpreted

Werner[1] noted that solutions of the potassium salt yielded coloured precipitates with cupric, ferric and cobaltous chlorides We have examined the copper complex, which may be formulated as

$$\mathrm{Cu[PtCl(Acac)_2]_2}$$

The infra-red spectrum of the solid is considerably changed from that of the potassium complex, the highest frequency in the carbonyl region being 1,620 cm^{-1} Unfortunately, the compound is insoluble in water and organic solvents so that no infra-red or nuclear magnetic resonance measurements have been carried out on solutions. In spite of this it seems reasonable to believe that the copper is co-ordinated to the free oxygens of the carbon-bonded acetylacetone

The unequivocal determinations of the stereochemistry of KPt(Acac)$_2$Cl and the unusual bonding raises a number of interesting questions in relation to the structure and stability of d^8 complexes in general In addition to the above complexes, the compound KPt(Acac)$_3$ has been isolated The infra-red spectrum is complex and again has unusually high C=O stretching frequencies, the nuclear magnetic resonance spectrum shows the presence of two groups of methyl protons of intensity ratio 2 1 and with Pt—H coupling constants of 6 7 and ~2 c p s respectively. This may be taken to indicate that the stereochemistry of the complex is square planar with one 'normal' oxygen co-ordinated—and two γ-carbon co-ordinated—acetylacetone residues or, possibly, is five co-ordinate with two oxygen co-ordinated and one carbon co-ordinated ligand The corresponding Ni^{2+} anion is paramagnetic with a moment ($\mu_{\text{eff}}^{295°K} = 3\ 1$ B M) typical of that usually found for octahedral nickel complexes, its infra-red spectrum shows no anomalously high C=O absorption frequencies This probable change of co-ordination number in going from nickel (II) to platinum (II) complexes is similar to the structure differences between the monomeric Pt(Acac)$_2$ and the trimeric Ni(Acac)$_2^6$ Factors which may be involved in determining the co-ordination number of complexes of the first, second and third row of the transition elements have been summarized earlier[7]

Unusual co-ordination of acetylacetone through the γ-carbon atom has already, as was mentioned earlier, been observed in the case of Pt (IV) complexes by Swallow and Truter[4] It is interesting to note that the orientation of the acetylacetone group is quite different from that which we report here In considering the structure of the Pt (IV) complexes, it was suggested that the acetylacetone anion may be thought of as a substituted methyl group In the case of Pt (II), alkyl derivatives of the type L_2PtRX (R is the alkyl group, X a halogen and L a phosphine ligand) have been recently reported[8]. The stability of these complexes has been associated with the presence of the strong π-bonding phosphine ligands, which affect the stability of the complex to radical decomposition If one of the acetyl-acetonates in KPt(Acac)$_2$Cl is considered to be a substituted alkyl, a marked contrast of the present class of complex with those previously reported is obvious since acetylacetone is not generally considered to be capable of forming strong $p\pi$–$d\pi$ bonds with the metal This difference in stability may be correlated with the more probable decomposition of an anion in the case of acetylacetone

COINCIDENCE OF SUDDEN IONOSPHERIC DISTURBANCES WITH THE EXPLOSIVE PHASE OF SOLAR FLARES

By RICHARD HANSEN and JOSIP KLECZEK*

High Altitude Observatory, Boulder, Colorado

In a recent communication, Covington and Harvey[1] demonstrated the coincidence of the 'explosive' phase of solar flares with 10.7 cm solar noise bursts. Their investigation was based on a list of flares, optically observed at the Lockheed Observatory, which Athay and Moreton[2] reported as having had apparent ejections at velocities of 500–1,500 km/sec. The time of ejection has been called the 'explosive' phase as distinguished from the times of beginning and maximum brightness in the complete evolution of certain complex flares. We wish to show that the explosive phase is also accompanied by the beginning of sudden ionospheric disturbances. Further, we present two examples of solar limb flares with the explosive phase. Finally, a possible explanation of ionospheric 'sluggishness' is given.

Since the International Geophysical Year, the McMath–Hulbert, University of Hawaii, Sacramento Peak, and High Altitude Observatories have operated a network of identical instruments recording ionospheric disturbances, as evidenced by sudden cosmic noise absorption (SCNA) and sudden enhancement of atmospherics (SEA). The equipment and principles of operation have been described by Lee[3].

All eleven of the 'explosive' phase flares reported by Athay and Moreton occurred during periods of concomitant ionospheric observation, nine were accompanied by distinct effects. In two of the nine cases (*C* – August 24, 1959, and *K* – October 12, 1960) direct measurements of X-rays in the range 20–80 keV were made above the Earth's atmosphere[4]. The relationship between the starting time of the flare, its explosive phase, the starting time of the 10.7-cm burst, and the starting time of the SCNA or SEA is represented in Fig. 1. To provide identification, each event retains the same letter notation as the flares in refs. 1 and 2. Coincidence of the sudden ionospheric disturbances with explosive phases of the flares and with 10.7-cm bursts is evident. Our result corroborates the statistical studies by Dodson, Hedeman and Covington[5], Kawabata[6], Hachenburg and Kruger[7] of the association between ionospheric disturbances and centimetre-wave bursts. The association suggests a common physical cause, namely, high-velocity electrons[8] accelerated during the explosive-phase with the "flare X-rays generated in the same region of origin of emission as centimetre-wave bursts"[4].

Further evidence for ejection of particles is given by limb flares with explosive phase. Two examples will be described separately.

The cosmic-ray flare of November 20, 1960, has already been reported in the literature[9–11]. Its most noteworthy optical feature was a high-speed ejection, having an apparent transverse velocity of about 700 km/sec (Fig. 2*a*). The ejection began at 2022

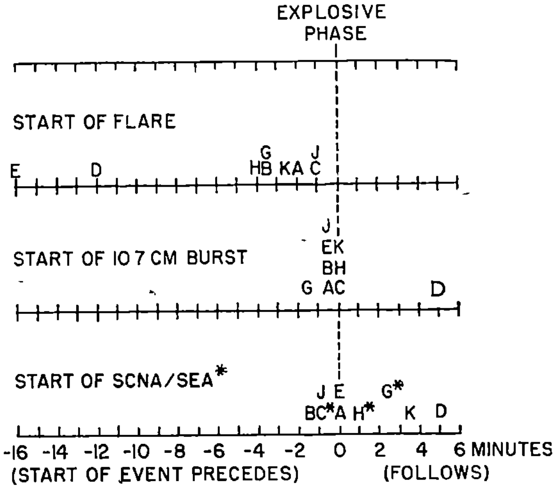

Fig. 1. Upper, distribution of the difference in time of start of the flare and of the explosive phase; middle, distribution of the difference in time of the start of the 10.7-cm burst and the explosive phase of the flare; lower, distribution of the difference in time of the start of the sudden cosmic noise absorption (SCNA) or sudden enhancement of atmospherics (SEA*) and the explosive phase of the flare. This is largely a reproduction of Fig. 1 from Ref. 1

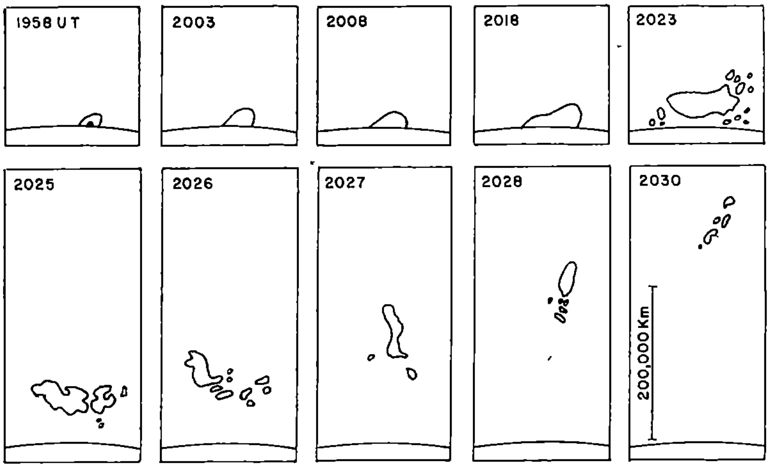
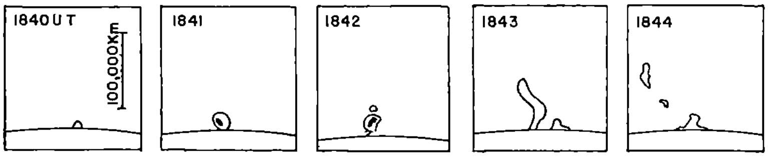


Nov 20, 1960



Aug 2, 1958

Fig. 2. Tracings of two solar limb flares with explosive ejections. The event of November 20, 1960 (25° N., 90° W.), is shown above and August 2, 1958 (13° S., 90° W.), below. All observations were made at the High Altitude Observatory, Climax

* American Astronomical Society visiting professor from the Astronomical Institute, Ondrejov, Czechoslovakia.

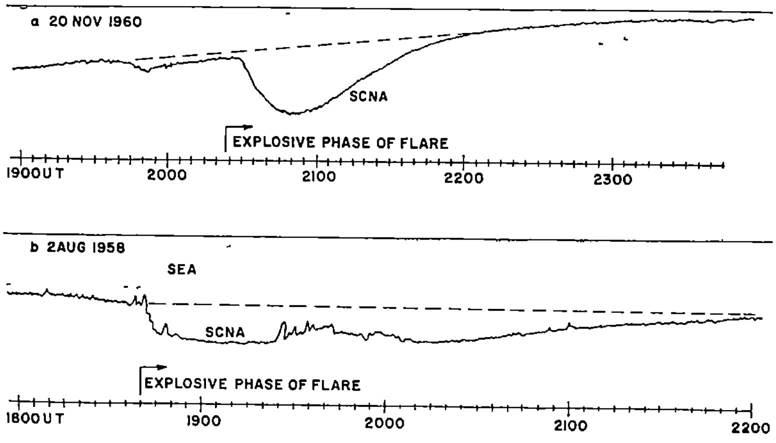

Fig. 3. Development of the ionospheric effects (SCNA and SEA) associated with the explosive phase of the solar flares shown in Fig. 2. The undisturbed trend of the 18 Mc/s cosmic noise is indicated by dashed lines

U.T. with the 10.7-cm burst starting at 2023 U.T. and the ionospheric disturbance starting from 2023 U.T. (SID and SEA) to 2028 U.T. (SCNA) (Fig. 3*a*). We believe this ejection to be the profile counterpart of the dark clouds reported by Athay and Moreton as being expelled from disk flares having explosive phase.

A very similar limb flare was observed at the Climax station of the High Altitude Observatory on August 2, 1958. A small, bright feature first appeared on the west limb at 1840 U.T., by 1842 U.T. it had clearly separated as an ejectual feature, continuing nearly radially outward from the Sun until 1847 when it was no longer visible (Fig. 2*b*). The transverse velocity was approximately 500 km/sec. Again, the microwave burst (1840 U.T.) and ionospheric effects (1841 U.T.) began essentially simultaneous with the ejection (Fig. 3*b*).

Some years ago, Ellison[12] noted the tendency for the maximum of the ionospheric effects to lag (by approximately 6 min) the maximum brightness of the optical flare. He attributed their delay to ionospheric 'sluggishness' due to the relaxation time associated with the production and decay of ionization in the ionosphere. The same author, however, has also directed attention to the 'flash of radiation' which occurs in the early stages of some great flares, intermediate between their first appearance and time of maximum brightness. This 'flash-phase' is certainly identical to what Athay and Moreton have called the 'explosive-phase', and the correct explanation of ionospheric 'sluggishness' is probably that the generation of solar X-rays is physically associated with the ejection of high-energy electrons at the explosive phase rather than with any other phase in the complex evolution of flares.

SPECTRA OF TURBULENCE AT HIGH REYNOLDS NUMBER

By Dr. M. M. GIBSON
Department of Mechanics, Johns Hopkins University, Baltimore

ENERGY spectra of streamwise and radial turbulent velocity components have been measured on the axis of a round air jet at moderately high Reynolds number, with the object of providing evidence for the Kolmogoroff universal equilibrium hypothesis[1].

Turbulent velocity fluctuations were measured initially with a conventional constant current hot-wire anemometer but afterwards, as the equipment became available, a constant-temperature hot-wire anemometer with a linearizing circuit was used. The turbulence signal was analysed with a 'Kronhite 330' variable band pass filter and a Hewlett–Packard 302*A* superheterodyne wave analyser, results from the two instruments overlapping in the wave number-range $0.2 < k < 1 \text{ cm}^{-1}$. In the use of the constant current hot-wire anemometer systematic errors arise from the inherent non-linear static (King's law) and dynamic response of the instrument to large amplitude velocity fluctuations[2] and from trigonometric non-linear response to large fluctuations in the direction of the local cooling velocity[3]. The second of these effects was reduced by using fine platinum–rhodium wires (0.000025–0.00005 in. diam.). Rough estimates of the error introduced by the non-linear static response may be made and it appears probable that the errors due to the first two effects tend to be self-cancelling in terms of the total turbulence signal, although the shape of the energy spectrum may be somewhat distorted.

Errors associated with large fluctuations in magnitude may be reduced by using a constant-temperature hot-wire anemometer with a linearizing circuit at the cost of random errors due to drift, with temperature, of the associated d.-c. coupled feedback amplifier circuits and a considerably reduced band-width due to the increased, and only approximately known, thermal noise. The errors associated with the response to the local flow direction have been examined by Rose[3] and may be corrected for the total signal.

Further systematic errors common to both systems were wire-length effects[4] (reduced in this constant current case by use of very short wires), and the assumption of the Taylor hypothesis to relate wave number to frequency $\left(k = \dfrac{2\pi n}{\bar{U}}\right)$

The results presented here have not been corrected for any of these effects, and in this connexion it is of considerable interest to compare the data obtained by the two methods. This has been done for the streamwise energy spectrum function $F_1(k)$ in Fig. 5. It is seen that agreement is surprisingly good, systematic divergence of the two curves being just apparent at very low wave-numbers. Numerical values presented here have been derived from the measurements with the constant-temperature hot-wire equipment considered to be, on the whole, the more accurate of the two.

The jet Reynolds number based on the 15·25 cm orifice diameter and the initial mean velocity was 5×10^5. On the axis, 50 diameters from the nozzle, the local mean velocity $\overline{U} = 600$ cm/sec, root mean square turbulence-levels in the streamwise and radial directions $\frac{u'}{\overline{U}} = 25$ per cent, $\frac{v'}{\overline{U}} = 26$ per cent, and the turbulence Reynolds number $R_\lambda = 780$, the value of λ being obtained from the relations valid strictly for isotropic turbulence only.

Figs. 1 and 2 are logarithmic plots of the energy spectrum functions $F_1(k)$ and $F_2(k)$ obtained directly by the two hot-wire methods with the definitions

$$\int_0^\infty F_1(k)\mathrm{d}k = \overline{u^2} \text{ and } \int_0^\infty F_2(k)\,\mathrm{d}k = \overline{v^2}$$

Fig. 3 is a semi-logarithmic plot of the energy spectrum function $F_1(k)$ of Fig. 2 and the corresponding dissipation spectrum $k^2F_1(k)$. The two spectra are reasonably well separated in wave-number space and the existence of an inertial sub-range therefore seems plausible. The curves of Figs. 1 and 2 are well fitted by a $-5/3$ power law over approximately two decades of wave-number for $F_1(k)$ and rather less for $F_2(k)$.

A method of checking local isotropy is to derive the spectrum function $F_1(k)$ from the measured $F_2(k)$ using the relation for isotropic turbulence[5]

$$\frac{\mathrm{d}F_2(k)}{\mathrm{d}k} = -\frac{k}{2}\,\frac{\mathrm{d}^2F_1(k)}{\mathrm{d}k^2}$$

in integral form. This has been done for the constant temperature hot-wire data of Fig. 2, the derived and measured values of $F_1(k)$ being plotted, for comparison, in Fig. 4. The moderately good agreement for $k > 0·2$ is, considering the limited accuracy of the method, at least an indication of local isotropy. The anisotropy of the large-scale turbulence is shown quite clearly by the systematic divergence of the experimental points from the derived curve at low wave-numbers. The same method applied to the constant current hot-wire data of Fig. 1 yielded less satisfactory results, although the error was in the opposite direction, due to the unexpected and unexplained low measured value of v'.

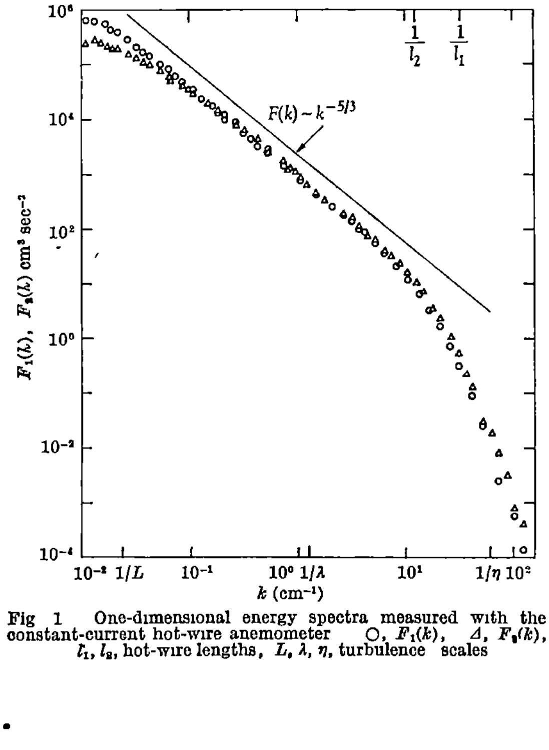

Fig. 1. One-dimensional energy spectra measured with the constant-current hot-wire anemometer. ○, $F_1(k)$, △, $F_2(k)$, l_1, l_2, hot-wire lengths, L, λ, η, turbulence scales

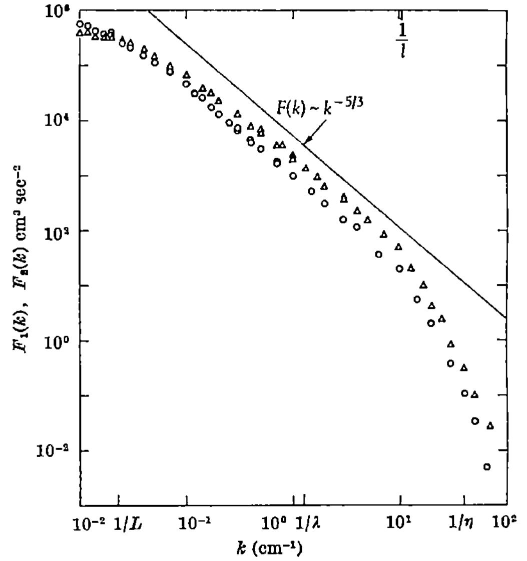

Fig. 2. One-dimensional energy spectra measured with the constant-temperature hot-wire anemometer. ○, $F_1(k)$, △, $F_2(k)$

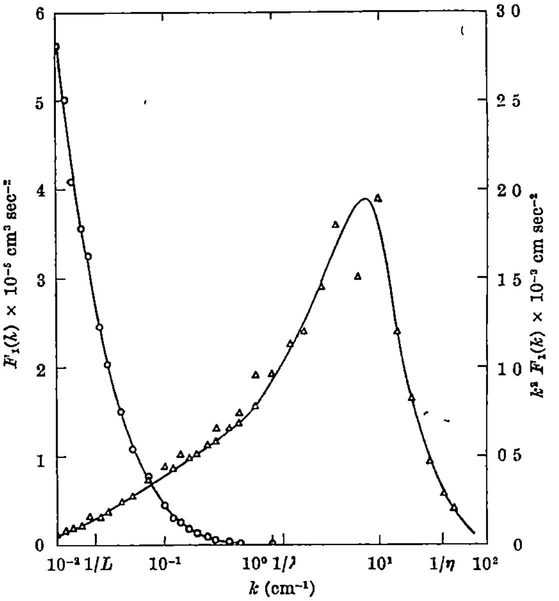

Fig. 3. ○, Energy spectrum $F_1(k)$, △, dissipation spectrum $k^2F_1(k)$

Assuming, then, local isotropy and the form of the three-dimensional energy spectrum predicted by the Kolmogoroff hypothesis for the inertial sub-range

$$E(k) = A\,\varepsilon^{2/3}k^{-5/3}$$

where

$$\int_0^\infty E(k)\,\mathrm{d}k = \frac{\overline{3u^2}}{2}$$

for isotropic turbulence, we obtain, with the relation $E(k) = -k\frac{\mathrm{d}}{\mathrm{d}k}[F_2(k) + \frac{1}{2}F_1(k)]$ (ref 5), a value for the postulated universal constant A compared in Table 1 with those found by other authors

Table 1

Ref	Flow	R_λ	A
Present work	Jet	780	1 57
6, 7	Tidal channel	3,600	1 44
8	Grid turbulence	750	2 70
9	Pipe	290	1 96

Bearing in mind the different conditions under which the data of Table 1 were obtained and the associated experimental difficulties, the four values of A reported are remarkably consistent and appear to bear out the Kolmogoroff theory for an inertial sub-range Some reservations must, however, be expressed with regard to the last two results Those of ref 8 appear to contradict the local isotropy hypothesis although, unfortunately, the wind tunnel used in this investigation was demolished before these unexpected effects could be properly examined The turbulence Reynolds number of the pipe flow of ref 9 scarcely seems high enough for the existence of an inertial sub-range and the shapes of the cross-stream spectra seem to bear this assumption out.

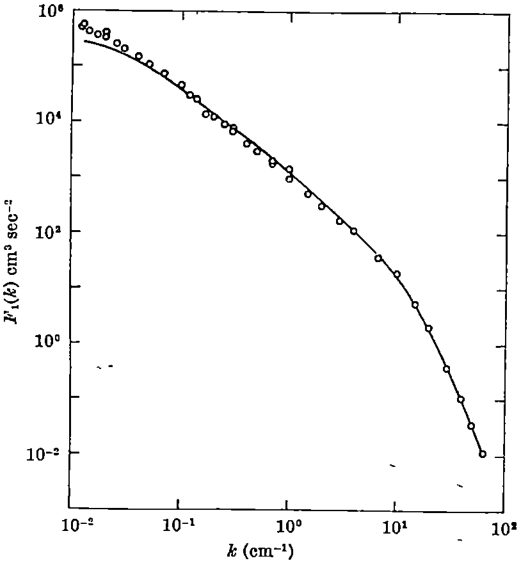

Fig 4 Solid line, $F_1(k)$ determined from $F_2(k)$, O, measured $F_1(k)$

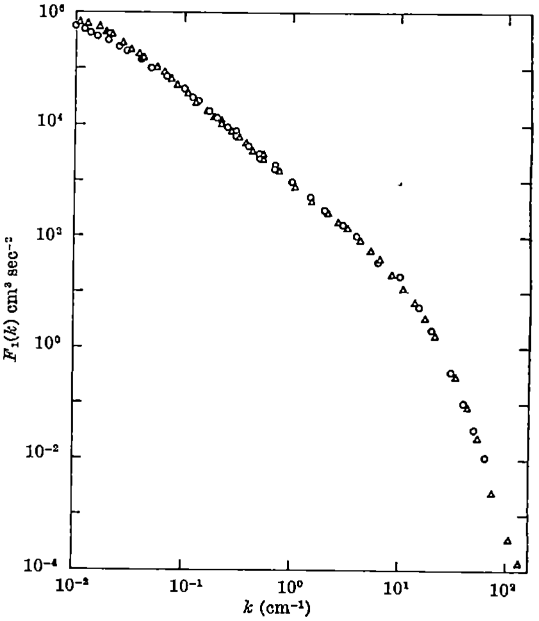

Fig 5 O, Results from constant-temperature hot-wire anemometer, Δ, results from constant-current hot-wire anemometer

Further measurements are clearly called for, and some are now being made in a region of the jet where the flow is highly non-isotropic and the turbulent shearing stresses are large

I thank Prof S. Corrsin for his advice and Dr W G Rose and Mr D A Kennedy for many helpful suggestions.

NATURE OF NUCLEAR DEBRIS IN SEA-WATER

By E C. FREILING and N. E. BALLOU

U S Naval Radiological Defense Laboratory, San Francisco, 24, California

IN a previous communication[1] 'fractionation' was defined as "any alteration of radionuclide composition occurring between the time of detonation and the time of radiochemical analysis which causes the debris sample to be non-representative of the detonation products taken as a whole" Fractionation resulting from the initial nucleation, condensation and separation processes was called 'primary fractionation' and discussed at length Subsequent fractionation due to contact of debris with radioactively inert surroundings was called 'secondary fractionation' This article is concerned with secondary fractionation in nuclear detonations occurring in the presence of sea-water Specifically, it summarizes studies carried out at the U S Naval Radiological Defense Laboratory up to the time of the moratorium on nuclear testing (October 1958) on the distribution of detonation product radionuclides between soluble, particulate and colloidal states It thus helps to establish the nature of radioactive contaminants of sea-water from nuclear detonations This information is pertinent to questions of the biological fate and the contamination and decontamination characteristics of such radioactive species. The work was carried out by a number of investigators, and involved investigations of both simulated and actual debris.

This report is essentially a progress report. Although the results presented are therefore not to be regarded as complete, they represent the best available information on this hitherto untreated subject. The extent of agreement among results from different detonations and from laboratory experiments simulating such events is greater than might at first be predicted.

Debris Formation

Little is known of the fundamental processes of nuclear debris formation in a sea-water environment. In the absence of large quantities of ballast or bottom material, the initial processes can probably be visualized, for orientation, as being similar to those of an air burst. The debris will consist initially of vaporized and dissociated water, sea-water salts and device materials. By applying an assumed efficiency to the thermal yield of a 10-*KT* device, detonated on the ocean surface, one calculates that the order of 1,000 tons of sea-water will be vaporized. If this device contains 1 ton of iron, the fireball will then contain 19 tons of chlorine, 11 tons of sodium and potassium, 1·6 tons of calcium and magnesium, 1 ton of iron, 0·9 ton of sulphur and less than 0·1 ton of any other sea-water constituent. Engulfed air will also be present. As this system cools, nucleation of the debris should be governed by iron, calcium and magnesium oxides. Thus, Stewart[2] estimates iron nucleation in an air burst would occur at 1,920° K, well above the boiling point of sodium chloride (1,686° K) and the sublimation point of sodium monoxide (1,550° K) but below the melting points of magnesium oxide ($\sim$2,880° K) and calcium oxide (2,840° K). Initial nucleation would take place in an atmosphere of undissociated water (which at this point can be neglected) and at concentrations not too different from those of an air burst. The initial nuclei would therefore be expected to consist of particles of calcium, magnesium and iron oxides of less than 20μ diameter, perhaps with a log normal, exponential or bimodal frequency distribution[2]. These would contain the refractorily behaving radionuclides. On further cooling, these would serve as nuclei for deposition of salt crystals, more volatile radionuclides, and eventually water or ice. Return to the sea-water would then be accompanied by dissolution of the condensed salt and late condensing soluble fission products, leaving colloidal particles bearing most of the activity. Due to the large surface to volume ratio, leaching of soluble radionuclides should occur with high efficiency, the more so since most of these would also be expected to have concentrated in the surface in particle formation, leaving the insoluble radionuclides in the colloidal state.

In the case of an underwater burst, a rapidly expending shell of vaporized device material first pushes the sea-water back, forming an expanding bubble. If the burst is sufficiently deep, this expansion reaches a maximum, and the bubble begins to contract. During these processes, the vaporized device material will be condensing and mixing with the vaporized sea-water. Unless bottom material is incorporated into the bubble, small particles are again formed. The greatest difference between the underwater burst and the surface burst, so far as the nature of the debris is concerned, is in the degree of primary fractionation. The degree of primary fractionation is dependent on the depth of burst. Thus, in the Shallower Underwater Burst examined here, slightly fractionated water, which was 25 per cent poor in strontium-89 in respect to the bulk of the fission products, appeared at surface zero. The missing strontium-89 appeared in the accompanying base surge, which was rich in strontium-89 by a factor of 2,000. In this case too, then, a large proportion of colloidally bound activity is to be expected in the water at surface zero.

If bottom material is incorporated, as was the case for the Lagoon Burst examined here, large particles and primary fractionation are naturally expected.

Except for Table 4, the results in this report are presented in forms which eliminate any effect of primary fractionation and illustrate only the effect of secondary fractionation.

Ultrafiltration

In view of the foregoing considerations a method of separating colloidal material from solutions is evidently required for the study of nuclear debris in sea-water bursts. High-pressure ultrafiltration through Visking dialysis tubing was used throughout these studies. The apparatus was based on a model described by Cummins[3], but metal surfaces were coated with inert material to minimize surface adsorption and voltaic cell formation. This has eventually led to the design of a plastic-lined ultrafilter by Callahan and Lai[4], although this came too late for the present work. Membrane testing has been carried out by Greendale and Ballou[5], and Chandler[6] and by Callahan and Lai[4]. Greendale and Ballou showed that the membranes would pass molecules of 12 Å diameter but retain particles of 30–40 Å diameter. The average pore diameter is rated by the manufacturer as 24 Å. In 1955, Chandler tested small fractions of the filtrate of radioactive solutions and found an ion retardation effect which was confirmed by Callahan and Lai. It is therefore important to bear in mind that ultrafiltration does not produce sharp separations but a gradation of retardations which increase with the size of the solute or colloid and may be influenced by the charge of the latter and the nature of the filtering medium as well.

Underwater Arcing Experiments

Greendale and Ballou[5] simulated the conditions of an underwater nuclear burst by vaporizing individual fission product radionuclides under sea-water in a carbon arc. The resulting mixtures were separated into particulate, colloidal and soluble fractions by centrifugation and by ultrafiltration through 'Cellophane' membranes. The results of duplicate runs (quadruplicate in the case of Sr) are shown in Table 1. The elements iodine, strontium, antimony and cæsium were found to be mainly soluble. Molybdenum was present chiefly as a colloid or particulate. Cerium, niobium, ruthenium, yttrium and zirconium were essentially particulate.

Underwater Burst

Physical-state investigations of debris from an underwater nuclear burst were carried out by Ballou, Richter, Wiltshire and Singer[7]. Surface-water samples and deep-water samples from this event were collected in polyethylene bottles, and aliquots of these were withdrawn for physical-state separations up to one month after zero time. Centrifugation was used to separate out a 'solid' fraction,

Table 1. PHYSICAL STATES OF SELECTED FISSION PRODUCT ELEMENTS FOLLOWING VAPORIZATION UNDER SEA-WATER

Element	Physical state (per cent) Soluble	Colloidal	Particulate
Ru	0.7 ± 0.5	3.5 ± 0.5	96 ± 1
	0 ± 1	6 ± 1	94 ± 1
Ce	1 ± 2	4 ± 6	95 ± 3

	53 ± 3	36 ± 6	11 ± 0.7
Sb	81 ± 1	6 ± 1	13 ± 1
	65 ± 0.3	23 ± 0.4	12 ± 0.1

and ultrafiltration of the resulting supernatant solution served to separate out a colloidal fraction. No visible solids were observable in the samples, and the significance of the differentiation between solid and colloidal fractions was afterwards discounted.

The percentage of total activity in the soluble phase as a function of time was determined by comparing β-disintegration-rates of gross samples with those of ultrafiltrates from successive separations. The decay curves of gross unseparated samples and of ultrafiltrates were quite similar, and consequently the percentage of total activity in the ultrafiltrate was rather insensitive to the length of time between the separation into fractions and the assay of activity. The results, plotted in Fig. 1, show that during the first day or so following detonation, approximately 35 per cent of the total radioactivity was in the soluble fraction. Separations at later times gave increasing relative amounts of radioactivity in the soluble fraction, and by two weeks after detonation this amount was up to approximately 60 per cent. This rise is attributed to the slow conversion of some of the constituent elements into a greater proportion of soluble material, rather than to the element composition changing through radioactive decay. Within the precision of the experiment, there is no apparent difference between samples, whether collected at the surface or at various depths.

The distribution of a number of radionuclides between soluble and insoluble fractions was determined on three surface samples. The percentages of the activity of each radionuclide in the ultrafiltrates at common reference times is given in Table 2. Sufficient data could not be accumulated to permit correlation of the above solubility behaviour of total radioactivity with that of individual constituents.

Average		42	65	50	71	34	0	35

* RE, gross rare earths and yttrium

With the exception of tellurium, in all cases where comparisons can be made, the fraction of activity in the ultrafiltrate in the arcing experiments described above is lower than that observed here. This may be due to the presence of milligram quantities of precipitate (hydrous iron oxides and carbon) in the arcing experiments.

Shallower Underwater Burst

Investigations similar to those performed by Ballou *et al.*[7] were made on a surface-water sample from a somewhat shallower underwater burst[8]. This sample was collected in a polyethylene bottle 2 h after shot time in the vicinity of surface zero. The sample contained no visible solids.

A series of sedimentation, centrifugation and filtration experiments were performed on this sample in an effort to determine the distribution of gross γ-ray activity with particle size. From the results of these experiments, the depletion of gross γ-ray activity produced by removing particles up to a given size was plotted against the calculated size of the particles. The results are shown in Fig. 2. An integral curve is drawn through the experimental points and a differential histogram has been constructed. The histogram is seen to decrease gradually with increasing particle size from 0.002 to 20μ.

Duplicate aliquots of this sample were ultrafiltered at various times over a period of 2–13 days after zero time. The fraction of gross γ-ray activity on the membrane was determined by comparing the activities of the membrane and of a standard aliquot of the gross sample immediately after ultrafiltration. The measurements were made in a γ-ray ionization

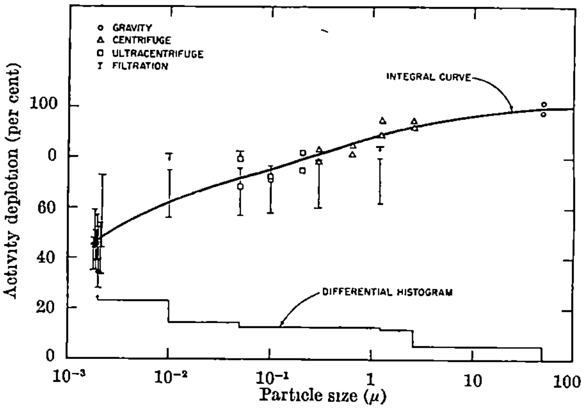

Fig. 2. Activity-particle size plot for $H+2$ surface-water sample, Shallower Underwater Burst

chamber Roughly equal divisions of gross activity were found after separation This is in agreement with the results from the Underwater Burst shown in Fig. 1 Decay measurements indicated that membrane activity decayed more rapidly than the activity of the ultrafiltrate, showing that fractionation was induced by the ultrafiltration process When the γ-ray activities of all membranes were measured at the same time, it was found that the membranes obtained later were more radioactive This observation could be explained by the gradual chemical conversion of radioactive species from the soluble to the insoluble state or by a change of gross radionuclide composition due to radioactive growth of a daughter radionuclide which associates itself with the insoluble (membrane) fraction In view of the results for the Underwater Burst and the known presence of the ^{140}Ba-^{140}La pair, the latter explanation is preferred

Radiochemical analysis for selected radionuclides was performed on duplicate aliquots of the gross samples, ultrafiltrates, and dissolved membranes. Results from successively separated fractions did not reveal any change in the physical state distribution of any radionuclide with time, but mass balance deficiencies prohibit firm conclusions in some cases The results from successive ultrafiltrations have therefore been averaged The results for each radionuclide are individually presented and discussed here and compared with the results of the two previous investigations Included in each discussion is the mass balance achieved and the effect of an additional membrane on the physical state distribution and mass balance observed Mass balance deficiency may be taken as a measure of contamination potential, since it presumably arises from adherence of the radioactive species to the walls of the polyethylene container or to the surfaces of the ultrafilter apparatus Results of experiments to determine the degree of deposit of several radionuclides on polyethylene surfaces from sea-water solutions are given in ref 8

^{89}*Sr* An average value of 4 ± 1 per cent of the strontium-89 was found to be in the insoluble phase, and an average mass balance of 116 ± 5 per cent was obtained The results show a somewhat greater solubility than that found in the underwater arcing experiments, but not outside the precision of the methods The results were unaffected by the presence of a second membrane

^{95}*Zr*–^{95}*Nb* Analyses were performed for both of these radionuclides, and no distinction between their behaviour was evident The presence of a second membrane increased both the mass balance and the percentage of activity appearing in the colloidal fraction With either a single or double membrane, 0–8 per cent of the activity was found in the soluble state, in fair agreement with the underwater arcing results With only a single membrane, an average of 48 per cent was found to be insoluble, but the results spread from 34 to 66 per cent The results from the deeper underwater burst are within this range

^{99}*Mo* Mass balance was consistently good, averaging 102 ± 5 per cent Using a single membrane, an average value of 68 ± 5 per cent was found to be soluble, in good agreement with the deeper underwater burst results With a double membrane, 26 ± 5 per cent was found to be soluble, in agreement with underwater arcing results

^{103}*Ru* It was found that 82 ± 5 per cent of the ruthenium was insoluble, the mass balance being 105 ± 6 per cent No double membrane effect was noted The solubility is therefore greater than indicated by the value of 1 per cent from the underwater arcing experiments

^{132}*Te* The insoluble fraction was found to contain 64 ± 9 per cent of the activity and the mass balance was 81 ± 12 per cent No double-membrane effect was noted These results are in better agreement with those from underwater arcing than with those from the deeper underwater burst

^{140}*Ba* This radionuclide showed a much higher solubility than the single determination made for the deeper underwater burst would indicate Only 5 ± 1 per cent was found in the insoluble fraction, the mass balance being 88 ± 4 per cent No double-membrane effect was noted The results are similar to those obtained for strontium-89

Total rare earths The insoluble fraction contained 67 ± 3 per cent of the activity, in accord with the deeper underwater burst results, but the mass balance was only 71 ± 3 per cent No double membrane effect was noted ^{141,144}Ce was found to behave similarly This behaviour is not inconsistent with the results from the underwater arcing experiment, where it was found to be soluble to the extent of 3 per cent or less

^{237}*U*. The insoluble fraction contained 46 ± 5 per cent of the activity, but the percentage of activity found in the soluble fraction was quite variable The deeper underwater burst results also indicate considerable variability No double membrane effect was noted

^{239}*Np* With single membranes, 50 ± 2 per cent of the activity was found to be insoluble, in agreement with the deeper underwater burst results. With a double membrane, however, 93 per cent was found to be insoluble As in the case of uranium-237, the percentage of activity found in the soluble fraction was quite variable

Lagoon Burst[8]

Another set of similar investigations has been carried out on an underwater burst which contacted the bottom of a coral lagoon Sample collection and treatment were similar to that performed on the shallower underwater burst, with two exceptions First, in addition to a surface water sample collected at 2 h after detonation time ($H + 2$), physical-state studies were also performed on a sample collected from the vicinity of surface zero at 20 h after detonation time ($H + 20$) Secondly, the presence of visible solids in the $H + 2$ sample allowed the initial separation of a particulate phase prior to ultrafiltration This was accomplished by filtration through a siliconed glass-wool plug in a siliconed funnel In order to achieve better definition of the particle size distribution, additional filtrations were made with 'Millipore' filters of various rated pore sizes

The distribution of gross γ-ray activity with particle size is shown in Figs 3 and 4 In the $H + 2$ sample, activity peaks corresponding to two different particle sizes are seen, one at about 10μ and one in the neighbourhood of 0 002μ The larger particle peak is missing from the $H + 20$ sample Comparison of gross activities of the filtrate and particle size fractions showed that the 10μ peak was effectively removed by the filtration with a siliconed glass wool plug

The radionuclide distributions found at 31 h after detonation in the surface water sample collected at $H + 2$ are given in Table 3 Solid phase refers to

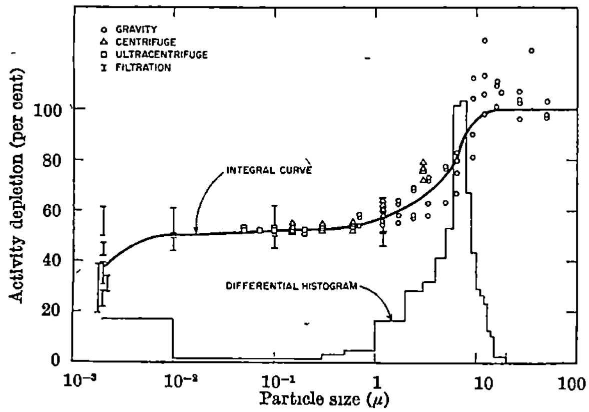

Fig 3 Activity-particle size plot for $H+2$ surface-water sample, Lagoon Burst

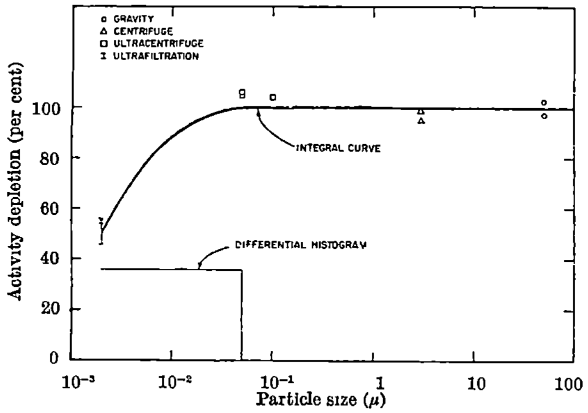

Fig 4 Activity-particle size plot for $H+20$ surface-water sample, Lagoon Burst

material removed by filtration through siliconed glass-wool, colloidal phase to material removed by ultrafiltration, and soluble phase to material remaining in the ultrafiltrate Standard deviations were calculated from duplicate analyses Deviation of sums from unity indicates lack of mass balance or tendency to contaminate

Except for molybdenum-99, the results obtained by analysis of the soluble phase are in fair agreement with the underwater arcing results As pointed out earlier, milligram quantities of hydrous iron oxide were present in the arcing experiments Although different precipitates were present in samples from the arcing experiments and from the coral lagoon burst, the presence of any precipitate would tend to make solubility results from these two situations more nearly alike Comparison of results on the other two phases, however, shows no consistency of agreement The soluble phase values for ^{89}Sr, ^{95}Zr, ^{95}Nb, ^{99}Mo and ^{140}Ba are in fair agreement with the shallower underwater burst results using a single membrane

* TRE, total rare earths

In order to compare laboratory filtration results with the results of the natural separation brought about by sedimentation in the lagoon, the gross $H+20$ surface-water sample composition is compared in Table 4 with $H+31$ and $H+41$ filtrate compositions obtained from the $H+2$ surface water samples Except for strontium-89, the values in a column are fairly constant Radiochemical analysis showed that the $H+2$ surface water samples were fractionated with respect to strontium-89 Since the $H+20$ surface water sample was taken from a different location, the strontium-89 deviation may easily be attributed to fractionation The constancy of the other ratios indicates that the natural process was well approximated in the laboratory The lower values for the $H+20$ samples are probably due to natural dilution or to sampling an originally less-active zone

Table 5 VARIATION OF SOLID COMPOSITION OF $H+2$ SURFACE-WATER SAMPLES WITH TIME (RELATIVE ACTIVITY PER μg CALCIUM)

	$H+31$ Filtration	$H+41$* Filtration	Duplicate $H+120$ Filtration	Duplicate $H+120$ Filtration
^{95}Zr	1 00	(0 52)†	1 00	1 11
^{95}Nb	1 00	(5 0)	1 00	1 09

^{103}Ru	1 00	1 14	1 52	1 67
^{132}Te	1 00	1 01	1 73	1 63
TRE‡	1 00	1 01	0 97	(4 2)
^{237}U	1 00	5 03	8 22	10 7
^{239}Np	1 00	0 89	1 21	1 33

* No calcium analysis available Calcium assay estimated to be 10 per cent lower than the value for the $H+31$ filtration † Doubtful values are enclosed in parentheses ‡ TRE, total rare earths

Finally, the solid compositions per μg of calcium were calculated for radionuclides in solid fractions obtained from filtrations of the $H+2$ sample made at $H+31$, $H+41$ and in duplicate at $H+120$ These are related to $H+31$ solid composition in Table 5 for those radionuclides which were not predominantly soluble It is seen that the zirconium-95, niobium-95 and total rare earth compositions are constant The constancy of neptunium-239 composition is borderline All other radionuclide solid phase fractions increase with time, most remarkable being uranium-237

RADIO ASTRONOMY

Solar Temperature at 2-mm Wave-length

ONE of the items developed for microwave diagnostic purposes on *Zeta* is a harmonic-mixing superheterodyne radiometer, working at a wave-length of about 2 mm. This radiometer has been used together with a small radiotelescope for measuring the apparent temperature of the Sun at a wave-length of 2·04 mm.

The radiotelescope was 43 in. in aperture, and was designed on the Coudé system to obviate the necessity of moving the receiver to follow the apparent motion of the Sun. It was also given a Cassegrain configuration to increase the effective focal-length to 163 in., as the focal-length of the primary mirror (18·7 in.) was so short that the Coudé system became geometrically impossible. The feed horn was thus behind the primary mirror, and connected by a run of oversize wave-guide (*WG* 16, 1 in. × ½ in., outside dimensions) to the receiver below the telescope. An equatorial mounting with synchronous motor drive was provided.

Recordings of received power when the aerial was aimed at the Sun were made on two cloudless days in August 1961 as the Sun declined from its noon altitude towards setting. The received powers were converted into aerial temperatures by comparison with a gas discharge noise tube, itself calibrated against a heated wave-guide load, and these temperatures plotted logarithmically against the secant of the Sun's zenith angle. A least-squares-fit straight line was drawn through the experimental points, and its intercept on the temperature axis taken to be the aerial temperature which would be obtained if the aerial were above the atmosphere. The slope of the line gave the vertical atmospheric attenuation, 3·10 db and 2·57 db on the two days, and this measured attenuation was compared with a calculated Van Vleck value, using upper atmosphere radiosonde data provided by the Meteorological Office. The calculated attenuation was found to be 1·5 times the measured value, in approximate agreement with results obtained elsewhere[1]. The temperature plots are shown in Fig. 1.

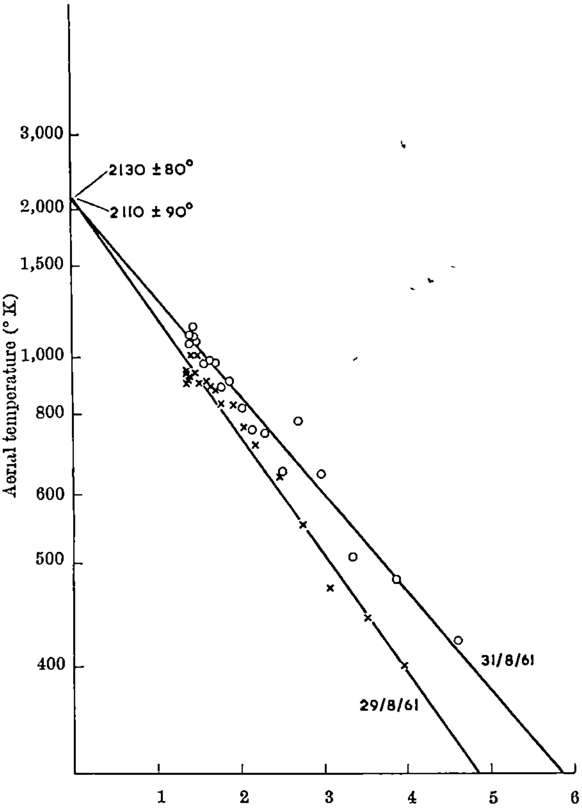

Fig. 1. Aerial temperature plots

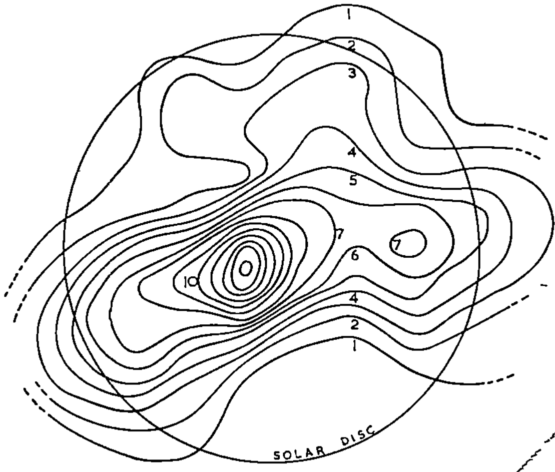

Fig. 2. Aerial gain pattern

The aerial was calibrated for the angular dependence of gain by transmitting a known power from an aerial of known gain at a distance of 930 m, which is more than twice the Rayleigh distance for the telescope, and measuring the power received as the telescope beam was scanned past the transmitter aerial. The gain pattern (Fig. 2) was integrated by planimeter over 14 contours, after superimposing the solar disk, and the result used for determining the true solar temperature from the observed aerial temperatures. Allowance was made for the atmospheric attenuation over the 930-m path.

The final result obtained was

$$T_{\mathrm{sun}} = 5{,}670 \pm 230^\circ \mathrm{K}$$

The probable error quoted includes individual errors due mainly to 'statistical' error from the least-squares fit, calibration of standard noise sources, standard aerial gain measurement. All other measurements are believed to be better than ± 1 per cent.

A drift curve, produced by locking the aerial and allowing the Sun to drift through the beam, is shown in Fig. 3 (receiver output time constant 16 sec). Theoretical points assuming the solar disk to be of uniform brightness from centre to limb are also shown.

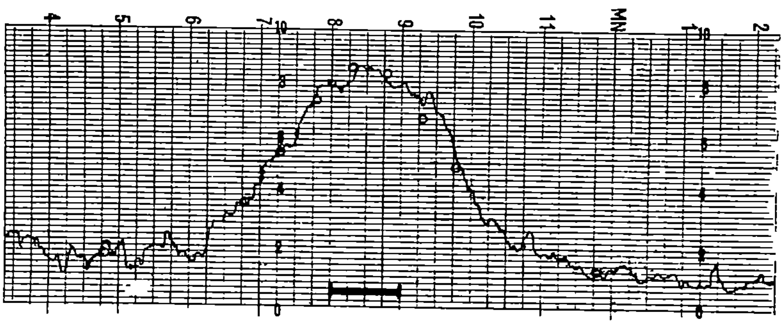

Fig. 3. Drift curve recording

This result may be compared with that reported by Tolbert *et al.*[1] of 5,433° ± 500° K at a wave-length of 2.15 mm.

These results appear to indicate that the Athay radio model of the chromosphere[2] requires some adjustment, in particular that the temperature of the 'cold' component of the chromosphere in the model is some 800° K too high.

I thank members of the Royal Radar Establishment, Malvern, who designed and constructed the radiometer, the N.I.R.N.S., Harwell, the Meteorological Office, and the Culham Laboratory.

Polarization in the Central Component of Centaurus *A*

Using the recently completed 210-ft. radio telescope[1,2] of the Australian National Radio Astronomy Observatory at Parkes, New South Wales, we have detected linear polarization of the radio emission from the central component of Centaurus *A*. Many maps of this object have been made[3,4], and more recently Hindman and Wade[5] and Bolton and Clark[6] have shown that it consists of two major extended sources several degrees in extent, together with a central core. The central component, which is closely associated with the galaxy *NGC* 5128, has been further resolved into two parts by Twiss, Carter and Little[7] and Moffet[8] using interferometers and by Little[9] using a fan-beam.

Bracewell[10] found that the fan-beam and existing interferometric data could be accounted for if the two sources were arranged on a diagonal running from north-east to south-west. An alternative disposition of the sources, at opposite ends of the dark band crossing *NGC* 5128, agreed with the equivalent ellipse established by Mills[11] and suggested a three-dimensional distribution in the form of a toroid. However, from the depth of the minimum observed between the peaks, it can be shown that such a toroid would have to be extremely thin (less than about 10″), and Little, Cudaback and Bracewell[12] and Little and Bracewell[13] concluded that it would be a more acceptable configuration if the two peaks were separate, more or less globular volumes. Maltby[14] determined the position angle of the line joining the two sources as 46.5°.

The separation of the two central sources is 7 min. of arc and they are partially resolved by the 6.7 min. beam of the 210-ft. reflector at 10.0 cm. As part of the research programme of the Observatory, studies of the object are being made at all available wave-lengths. Immediately prior to the present observations, equipment for feed rotation had been installed and tested at 10 cm on a number of known polarized and unpolarized sources by Dr. J. A. Roberts.

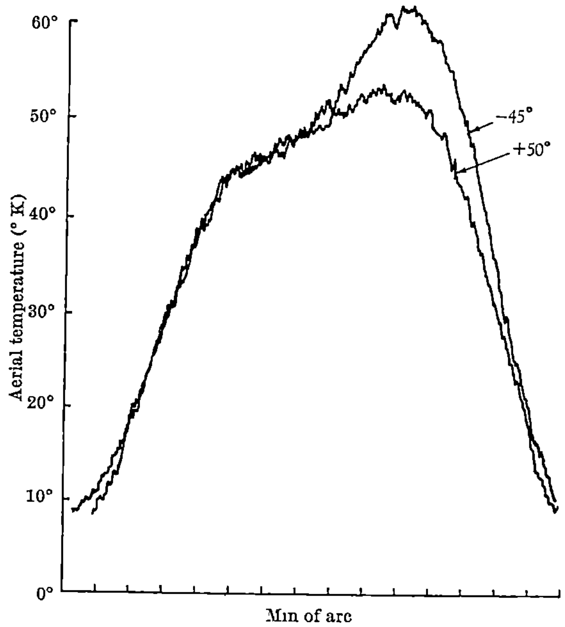

Fig. 1. Diagonal scans from north-east to south-west with polarization position angles of +50° and −45°

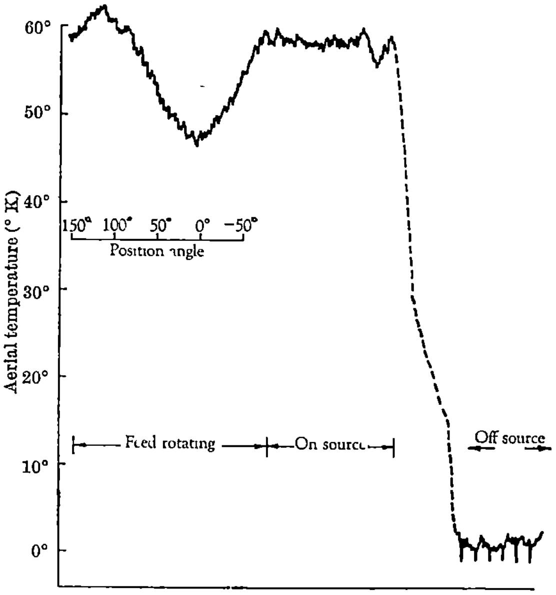

Fig. 2. Record taken near the maximum of the source with rotating feed horn

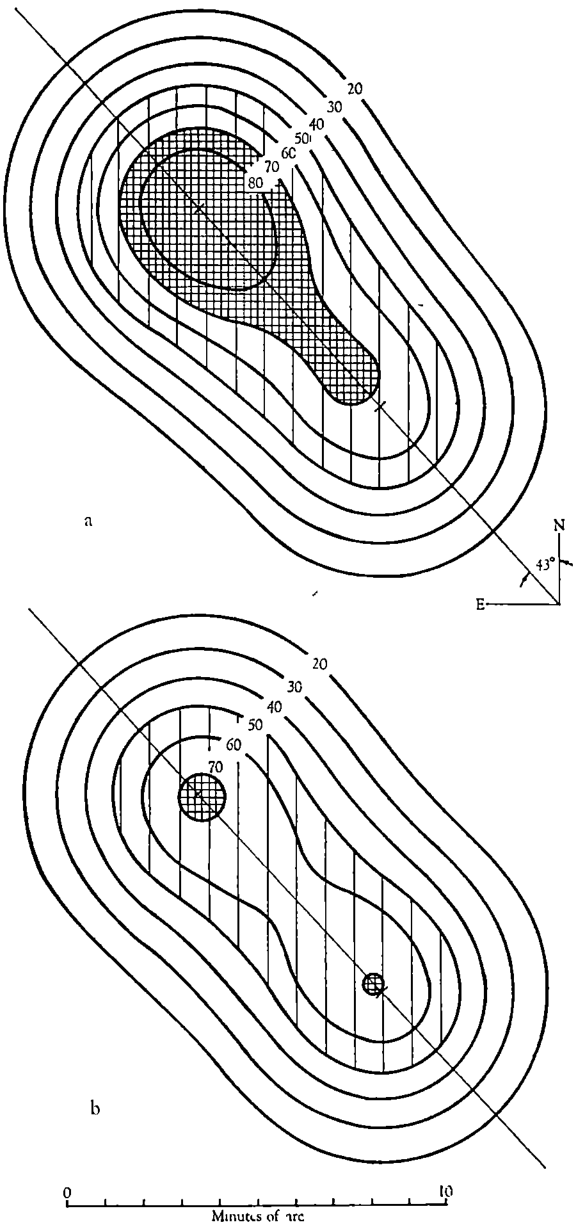

Fig 3 Contour diagrams of Centaurus *A* at 10 0 cm with polarization position angles chosen to exhibit maximum variation of the polarized component The position angle of the electric vector is (*a*) 115°, (*b*) 25° Contour unit, 0 7° K

Fig 1 shows typical scans made diagonally from north-east to south-west with the electric vector of the receiving horn in position angles 50 and − 45° It appears that the south-west component is unaffected by the change in polarization whereas the north-east component is

This conclusion was confirmed by rotating the feed horn through slightly less than 180° while tracking various points of the source An example is shown in Fig 2 This example shows a degree of polarization of 13 per cent, with the electric vector of the feed horn oriented in position angle 115° for maximum reception

Contour diagrams were constructed for position angles 50°, 0°, − 45° and − 90° These results are summarized in Fig 3, which shows the extreme contour diagrams for the position angles of 115° and 25° These diagrams represent our conclusion that the observations are consistent with the presence of two point sources lying on a line in position angle 43°, 7 min of arc apart, the north-east source being 15 per cent polarized in position angle 115 degrees The observations were matched by two gaussian humps of half-widths ~ 6′.7 and peak values of 78 and 66 contour units for the north-east (unpolarized part) and south-west components respectively To the accuracy with which the telescope is presently calibrated (~ 1′ arc) the two sources appear to be symmetrically placed with respect to *NGC* 5128

The degree of polarization is higher than has been observed for other cosmic sources[15], for example, the Crab nebula exhibits 3 per cent polarization at 10 cm and Cygnus *A* and Cassiopeia *A* have less than 1 per cent polarization At 3 cm the Crab nebula shows 7 per cent and Cygnus *A* 8 per cent polarization After allowance for the depolarizing effect of propagation through a medium containing a magnetic field the degree of polarization may be quite high, and it must be concluded that systematic orientation of magnetic field in the region of origin persists over vast volumes Assuming a distance of 4 megaparsecs to Centaurus *A*, and an angular diameter of 1 min of arc for a source, its diameter is about 1 kiloparsec It is apparent that such extensive magnetic fields play an important part in the behaviour of a galaxy and it should become possible to map the field pattern surrounding a galaxy by polarization observations

One of us (R N B) thanks Dr E G Bowen for permission to take part in the observations

Note added in proof Since this communication was written it has come to our notice that C H Mayer, of the Naval Research Laboratory, Washington, D C , has independently detected linear polarization in the central component of Centaurus *A* At 3 15 cm he finds a degree of polarization similar to that reported here

PHYSICS

Interferometric Measurement of Electron Density in *Sceptre IV*

THE density of free electrons in a plasma may be determined from its refractive index If electromagnetic waves are used, the frequency of which is greatly in excess of the plasma frequency and the electron cyclotron frequency, the refractive index is given by[1]:

$$(\mu_p - 1) = -4\ 46 \times 10^{-4}\ \lambda^2 N_e$$

μ_p is the refractive index, λ the wave-length (Å) and N_e the number of electrons per cm^3. Optical interferometer techniques have previously been used to measure electron densities of about 10^{17} cm^{-3} in shock waves[1-3] and of the order of 10^{14} cm^{-3} in radio-frequency discharges[4] This communication describes experiments to determine spatial and temporal variations in the electron density in a hydrogen discharge in *Sceptre IV*[5] over the density range 10^{14}–10^{16} cm^{-3} For the conditions used, the contributions of atoms and ions, both of hydrogen and impurities, to the refractive index can be neglected

The common-path interferometer[6] used for this experiment has several advantages It is easy to set up, requires only a moderately narrow wave-length spread and, as each beam passes twice through the plasma, the fringe shift for any electron density change is twice that in a single pass instrument such as a Mach–Zehnder interferometer No balancing of optical paths is required, and it is possible to compensate for any vibrations of the mechanical parts of the system. Fig 1 shows the optical arrangement, with the reference beam passing through the centre of the discharge tube and the test beam filling the aperture of the window, including two small evacuated tubes which provide information on the changes in density along the reference beam The diameter of the discharge tube bore is 30 cm The concave mirror, fixed on anti-vibration mountings on the iron core linking the torus, reflects the two beams back to the interferometer, which produces a pattern of horizontal fringes within a vertical image of the window aperture The dark zero-order fringe appears at the position at which the reference beam strikes the aperture This image is focused on to the plate of a rotating mirror camera after passing through a Wadsworth monochromator acting as a filter The interferometer was used with a cylindrical beam-splitting lens to make most effective use of the light from a 2 5 kW A E I xenon lamp Light from the discharge was effectively prevented from obscuring the interferogram by the polarization selection of the interferometer, by the monochromator and by means of suitable diaphragms

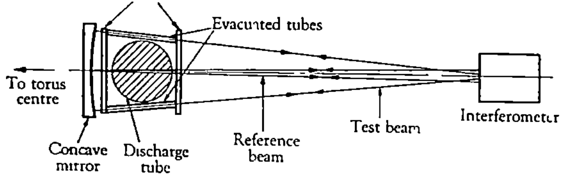

Fig 1 Optical arrangement

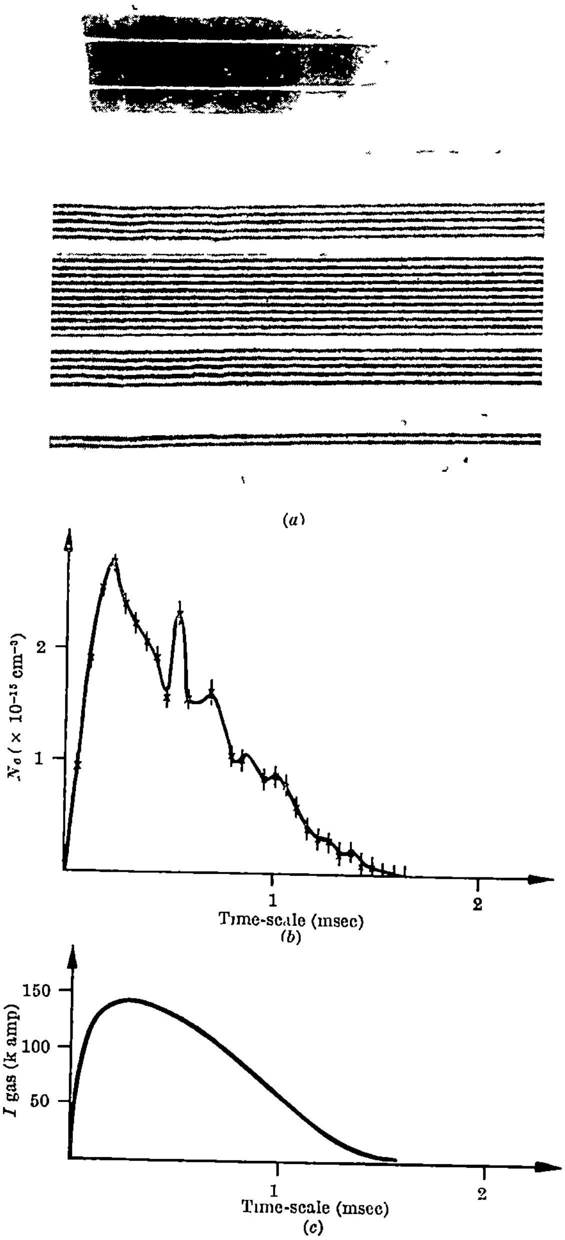

Fig 2 *a*, Rotating mirror photograph and interferogram, *b*, mean electron density along line across the centre of the tube *c*, gas current Discharge conditions $C = 912\ \mu$F, $V_c = 20$ kV, 8 1 turns ratio, 2 4 × 10^{-2} mm mercury of hydrogen, B_φ = 1,500*g*

The discharge light, observed through the same window by a different optical path, was recorded simultaneously on the plate and can be seen (in the form of a negative) above the example interferogram in Fig 2 The clear bands in both the discharge and fringe pictures are caused by copper bars across the window The fringes in the two small tubes can be seen on either side of the main fringe picture The orientation of the photograph is such that both discharge and fringe pictures are inverted A downward fringe shift in the evacuated tubes implies an increase in electron density at the centre of the discharge tube A downward shift at any other point in the interferogram implies an increase in the difference between the density at that point and that at the position of the zero order fringe, that is, a reduction in density The resolution time is about 30 μsec The mean optical wave-length chosen was 6200 Å

The upper curve in Fig 2 shows the mean electron density for the line across the centre of the tube obtained from the fringe shifts in the small tubes, and the lower curve is a current wave-form taken for the same conditions but for a different discharge The interferogram was taken for a discharge with a filling pressure of $2 \cdot 4 \times 10^{-2}$ mm mercury of hydrogen, an initial axial magnetic field of 1,500 g and a peak gas current of 140 k amp The maximum fringe shift is about 0 4 of an order The fluctuations in the density shown in Fig 2 are caused by movements of the region of peak density and by changes in the overall density The errors given in Fig 2 are absolute errors, the difference in density between two adjacent times is more precise and is indicated by the curve drawn through the points

The density peaks correspond closely to strong light emission from the centre of the tube An Abel integration across the tube to find the radial distribution of electron density gives a peak density at the centre of $3 \cdot 8 \times 10^{15}$ cm^{-3} At this time, the number of electrons in the tube was within 10 per cent of the initial number of atoms The maximum density was followed by 'pump-out'[7] and some form of rapid injection when the overall density rises before decaying to less than 10^{14} cm^{-3} in 1 6 msec from the start of the discharge These results, together with similar measurements at initial pressures of down to 2×10^{-3} mm mercury of hydrogen, will be described in a more detailed paper

We thank Dr A A Ware for advice, Messrs D Warren and A Ennos for their assistance in the experiments and Messrs L A Green and A C Richardson for operating *Sceptre IV* This work was supported in part by a U K Atomic Energy Authority contract We also thank Dr T E Allibone, director of the Laboratory, for permission to publish this communication

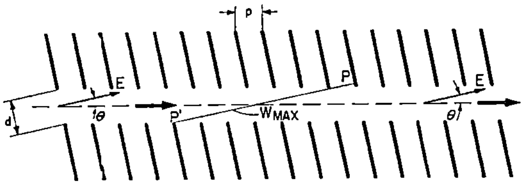
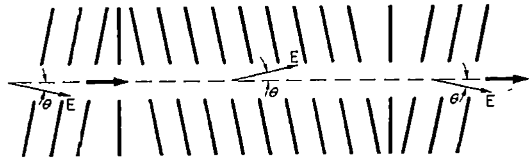
High-Voltage Acceleration Tubes utilizing Inclined-Field Principles

THE 'total voltage effect', which limits the voltage across an evacuated tube in a manner distinct from that of ordinary insulation, generally prevents a linear increase in voltage with an increase in tube-length for fixed voltage gradient along the tube Thus, although a tube designed for operation at 3 million volts may work very well, a similar tube twice as long does not usually satisfactorily insulate 6 million volts, even though the voltage gradient remains the same This breakdown, the precise nature of which is still obscure, is caused by the regenerative multiplication of secondary particles initiated within the tube by various causes such as cosmic rays, the primary beam, and field emission

This communication describes the performance of three large-aperture high-voltage tubes which have been developed to avoid the total voltage effect This was accomplished by inclining the central plane of the electrodes to the axis of the tube, thereby reducing the length of the electric lines of force to only a fraction of the insulating length of the tube (Fig 1*a*) It is desirable that secondary particles, particularly electrons, produced within the tube be limited to a maximum energy which is as low as feasible Since it may be considered that the electric field is uniform and that secondary particles are liberated with negligible energy, Fig 1*a* shows that a secondary particle attaining maximum energy is one liberated at point *P* on one electrode so that it barely misses interception on the adjacent electrode The angle of inclination, θ, and dimension, *d*, of the tube opening in the direction of inclination can be so chosen that this particle will barely be intercepted by another electrode



a NEUTRAL BEAM TUBE



b CHARGED PARTICLE ACCELERATION TUBE

Fig 1 Cross-sections of the central regions of two different inclined-field tubes showing the geometrical arrangements of the plane electrodes

The maximum kinetic energy acquired by a secondary particle will then be

$$W_{\max} = \left(p + \frac{d}{\sin\theta}\right) eE$$

where p is the axial inter-electrode spacing and E is the axial voltage gradient For a representative tube test $W_{\max}$ was calculated to be 360 keV when the total tube voltage was 5,760 kV As the expression is not affected by the aperture dimension perpendicular to the plane of the sections shown in Fig 1, slotted electrodes were used to increase the aperture area and the conductance of the tube

In this simple form a tube was successfully used to provide passage for an intense neutral beam However, this tube is evidently unsuitable for the acceleration of charged particles But, by alternating the direction of the inclined field in a calculated manner as illustrated in Fig 1*b*, an injected charged particle beam was accelerated through the modified tubes along a path which was very nearly axial Secondary particles still travel along the lines of force and are removed from the tube before they can enter a section of opposite inclination, except those formed near an intersection which may have a somewhat longer path It is worth noting that the operation of the inclined field tube depends upon the charge of the primary beam and not on the particle mass and therefore such tubes may also be used to accelerate an injected electron beam

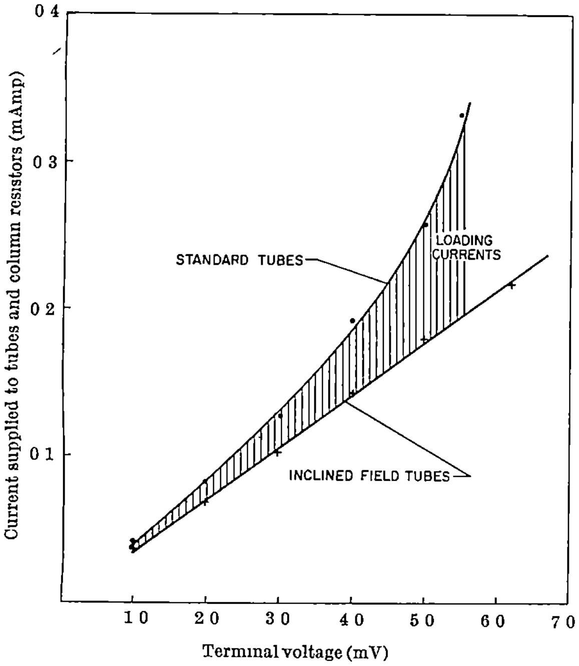


Fig 2 A comparison between the performance of standard and inclined-field tubes The shaded region shows the loading currents associated with standard tubes

The immediate removal of the secondary particles has various advantages Previously, even with the greatly improved acceleration tubes having electrodes tapered in diameter of aperture, which were developed by Prof J G Trump *et al* , many secondary electrons were accelerated along the total length of the tube Due to their high energy, these electrons produce undesirable and penetrating radiation On the other hand, the maximum energy of the X-radiation spectrum from the inclined field tubes was shown, by scintillation counter measurements, to be in close agreement with the calculated shortening of the secondary particle trajectories In addition, when standard acceleration tubes are used, the current drain due either directly or indirectly to the secondary particles must be compensated by an increase in the output current of the power supply maintaining the voltage across the tube This phenomenon, often known as loading, has generally limited the maximum current capability of electrostatic accelerators at the high end of the voltage-range The shaded region in Fig 2 shows, for standard tubes in a tandem accelerator, the rapid increase in regenerative loading with terminal voltage The inclined-field tubes show negligible loading as evidenced by the linearity of the lower curve, which is the effect of the column resistor current and would occur without the presence of the tubes In both cases the same beam current was accelerated

By using two of the inclined-field tubes each with an insulating length of 12 ft in a tandem accelerator, an analysed proton beam of 3 9 µamp was attained at 15 6 MeV. The background radiation from the machine was not only less penetrating than with conventional tubes, but also was reduced in intensity by a factor of about a thousand Maximum voltage could be applied immediately without the usual tube conditioning time No tube sparks were observed and the upper voltage limit was determined by factors other than the acceleration tubes

Since these tests show that the limitation in beam current due to regenerative side-effects was eliminated, it may be expected that far higher currents can now be accelerated In addition, the effective elimination of the total voltage effect makes it possible to increase maximum tube voltage linearly with tube-length The development of the inclined-field tube is continuing and more detailed results are in preparation for a subsequent publication

Direct Observation of Detonation in Compressed Nitromethane

Johansson and Sternhoff[1] have shown that the detonation light from some TNT-based explosives is suppressed under pressure from an externally produced shock wave We have observed similar behaviour in nitromethane where, in this case, the homogeneous liquid can be considered to be free of voids which may influence the emitted light A somewhat more indirect experiment has been described[2], wherein a detonating nitromethane charge was observed normal to the open end With proper under-boostering, weak light was observed which, after a time, suddenly changed to the normal detonation intensity The weak light was attributed to detonation of material compressed by the initiating shock wave

In the experiments reported here, the nitromethane was contained in an aluminium box having front and back sides of 1 5-in thick 'Plexiglas' and was loaded just prior to firing in order to minimize the solvent effect of nitromethane on plastic Under these conditions the 'Plexiglas' remains quite transparent until free surface motion begins[3] The detonation event was observed through the 'Plexiglas' by a Cordin framing camera at exposure times of 0 25 µsec duration

The experimental assembly is illustrated in Fig 1 The initiating explosive was 'Composition *C*-3'

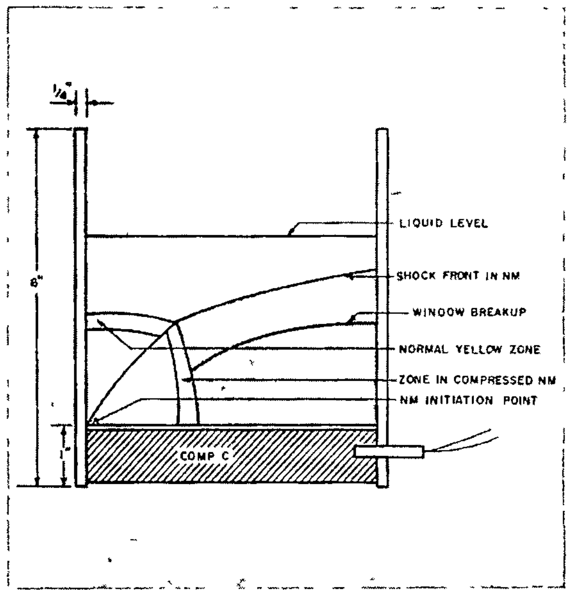

Fig 1 Diagram of experimental arrangement

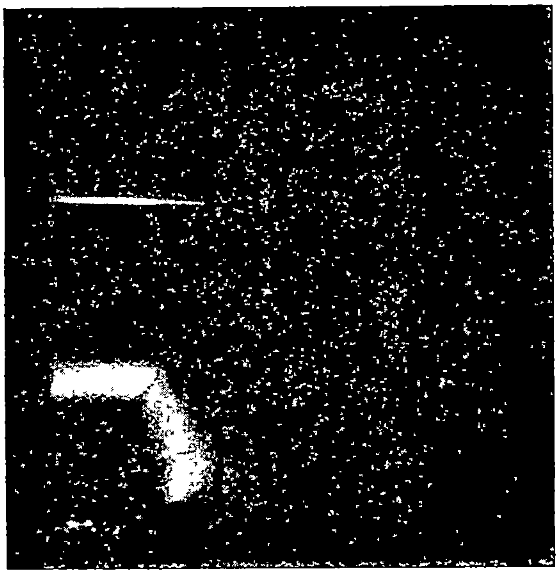

Fig 2 Detonation through normal (top) and shocked nitromethane

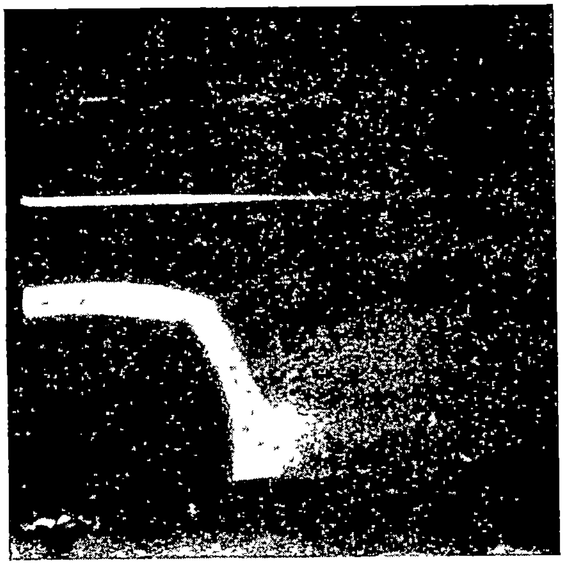

Fig 3 Interaction between detonation wave fronts in nitromethane

(detonation rate 7,600 m/sec), which drove a wiping shock wave into the nitromethane through the 1/8-in aluminium tank floor This shock was insufficient to initiate nitromethane directly but did so after reflexion from the opposite corner of the tank

The event was recorded on Eastman 'H S Ektachrome' film The film showed the normal bright yellow detonation proceeding upward into the unshocked liquid and a dim yellow, right-going, zone in the compressed explosive which maintained its identity throughout the sequence The experiment was reproducible Although the zones were easily distinguishable on colour film the brightness differences were not great and show to less advantage in black-and-white. An early frame is shown in Fig. 2 Fig 3, from the same sequence, was contrast-controlled during printing to show details of the window break-up and the interaction line behind the wave fronts The interaction line remained visible for some time and was, perhaps, etched into the 'Plexiglas' window Campbell *et al* [2] postulate a super-velocity detonation through the compressed region to explain the first dim light which they observed In view of these experiments, it seems reasonable to attribute weak detonation light to the reaction of compressed material Although there is some tendency for the wave in the compressed explosive to pull away from the normal front, it is not pronounced Compression to higher densities would be expected to increase that tendency

The photographs shown were taken without external illumination Similar experiments, which were illuminated with diffused backlight from an argon flash bomb, showed the compressed but undetonated nitromethane to be transparent while everywhere behind the two detonation fronts a black, opaque, reaction product cloud had formed We believe the opacity was due to free carbon from this oxygen-deficient explosive rather than opaquing of the 'Plexiglas' for two reasons (1) explosives having transparent reaction products have been used and in these cases the 'Plexiglas' windows transmitted backlight, (2) experiments with front-lighted nitromethane tanks, having white grid lines painted on the inside front surface of the 'Plexiglas' window, have shown that such grid lines remained clearly visible after passage of the detonation wave The lines remained visible until break-up of the window occurred.

RADIATION CHEMISTRY

The Effect of *p*H on the Radical Yields in the γ-Radiolysis of Aqueous Systems

It is customary to describe the state of affairs about 10^{-8} sec after the passage of a fast electron traversing a liquid aqueous medium by equation (1) ·

$$G_{\text{-H}_2\text{O}}\text{H}_2\text{O} \rightsquigarrow G_{\text{'H'}}\,\text{'H'} + G_{\text{OH}}\,\text{OH} + G_{\text{H}_2}\,\text{H}_2 + G_{\text{H}_2\text{O}_2}\,\text{H}_2\text{O}_2 \quad (1)$$

in which $G_{\text{'H'}}$ and G_{OH} are the numbers of H atoms and OH radicals respectively which are available to react with solutes for each 100 eV energy deposited in the water Recent work[1,2] has shown that the precursor of the hydrogen atom is a solvated electron, e^-_{aq}, capable of reaction in this form with solutes such as N_2O[3], $ClCH_2COOH$[4], O_2[2], H_2O_2[2], etc The solvated electron is also able to react with hydrogen ions according to equation (2), when it is converted into a hydrogen atom

$$\text{H}^+_{\text{aq}} + e^-_{\text{aq}} \longrightarrow \text{H}_{\text{aq}} \quad (2)$$

Consequently, as the *p*H of a solution is reduced a solute has less chance of reaction with e^-_{aq} and more of reacting with H It is also known[3] that reduction of the *p*H below ~ 3 causes the production in equal yield of two additional entities, stoichiometrically equivalent to H and OH and tentatively identified as H_2^+ and OH The fact that the molecular yields,

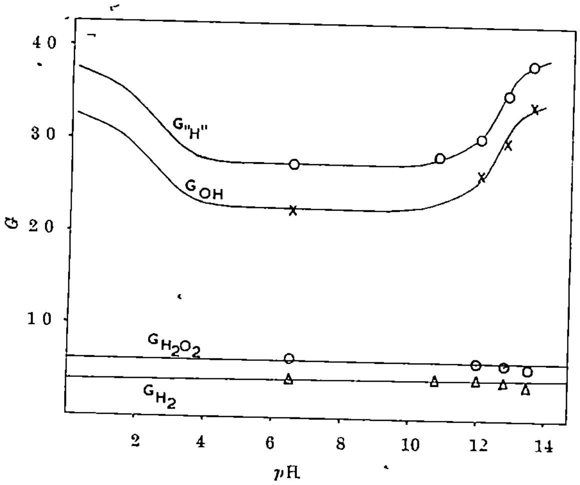

Fig 1 Variations with pH of $G_{'H'}$, G_{OH}, G_{H_2} and $G_{H_2O_2}$ for γ-irradiated liquid aqueous systems Lines at $p\text{H} < 6$ based on many previous investigations (see Fig 9, ref 3) Lines at $p\text{H} > 6$ based on the $Fe(CN)_6{}^{3-}$ — $Fe(CN)_6{}^{4-}$ — N_2O system described here and to which the experimental points refer

G_{H_2} and $G_{H_2O_2}$ do not diminish as the pH is reduced below 3, indicates that these entities are formed by the attack of the acid on some intermediate which otherwise (that is, at $p\text{H} > 3$) reverts to water, and the kinetics[3] indicate that the reversion is first order in intermediate concentration This intermediate may be either an excited water molecule, H_2O^*, or an isolated radical pair in a solvent cage, denoted by (H + OH) Its reaction with the acid is then represented by either equation (3) or (4)

$$H_2O^* + H^+_{aq} \longrightarrow H^+_{2\,aq} + OH_{aq} \qquad (3)$$

$$(H + OH) + H^+_{aq} \longrightarrow H^+_{2aq} + OH_{aq} \qquad (4)$$

Consequently, the conventional hydrogen atom yield $G_{'H'}$ is the composite quantity, $G_{e^-} + G_H + G_{H_2^+}$ The dependence of $G_{'H'}$ G_{OH}, G_{H_2} and $G_{H_2O_2}$ on pH below pH 7 is shown in the left hand part of Fig 1

$$H_2O^* + OH^-_{aq} \longrightarrow e^-_{aq} + OH_{aq} \qquad (5)$$

$$(H + OH) + OH^-_{aq} \longrightarrow e^-_{aq} + OH_{aq} \qquad (6)$$

We may envisage the reactions (5) and (6), which are the basic analogues of reactions (3) and (4), and we are therefore led to expect a perceptible increase of the conventional yields as the pH is increased above about 11 Satisfactory solutes for use in alkaline solutions are rare and we have therefore tackled this problem in the following manner First, we have shown that when acrylamide is used as a solute $G(H_2) = G_{H_2}$ and $G(H_2O_2) = G_{H_2O_2}$ undergo no sudden changes between pH 0 and 13 Secondly, we have shown that the only reactions occurring at $p\text{H} > 7$ in deaerated aqueous solutions containing potassium ferrocyanide, potassium ferricyanide and varying amounts of nitrous oxide are

$$Fe(CN)_6{}^{3-} + e^-_{aq} \longrightarrow Fe(CN)_6{}^{4-} \qquad (7)$$

$$N_2O + e^-_{aq} \longrightarrow N_2 + O^-(\rightarrow OH) \qquad (8)$$

$$OH + Fe(CN)_6{}^{4-} \longrightarrow OH^- + Fe(CN)_6{}^{3-} \qquad (9)$$

$$H_2O_2 + 2Fe(CN)_6{}^{3-} \longrightarrow 2H^+ + O_2 + 2Fe(CN)_6{}^{4-} \qquad (10)$$

Hence, for this system, we obtain the radical and molecular yields from equations (11)–(14) inclusive, in which the superscript, $- N_2O$, means no N_2O present and the superscript, $+ N_2O$, means that the N_2O concentration is sufficiently large for $k_8[N_2O] \gg k_7[Fe(CN)_6{}^{3-}]$.

$$G_{H_2O_2} = G(O_2) \qquad (11)$$

$$G_{H_2} = G(H_2) \qquad (12)$$

$$G_{'H'} = G(N_2)^{+N_2O} \text{ or } \{G(\text{ferri})^{+N_2O} - G(\text{ferri})^{-N_2O}\}/2 \qquad (13)$$

$$G_{OH} = G_{'H'} + 2\,G_{H_2} - 2G_{H_2O_2} = \{G(\text{ferri})^{+N_2O} + G(\text{ferric})^{-N_2O} + 4\,G(O_2)\}/2 \qquad (14)$$

The values of these yields are shown in the right-hand half of Fig 1, and their variation with pH is in accord with the proposed existence of reaction (5) or (6) At $p\text{H} \leqslant 6$ reaction (10) is replaced by the relatively slow reaction (15)

$$2\,Fe(CN)_6{}^{4-} + H_2O_2 \rightarrow 2\,Fe(CN)_6{}^{3-} + 2\,OH^- \qquad (15)$$

so that the measurement of the post-irradiation reaction and of the effect of N_2O on G(ferri) can be used to determine the radical and molecular yields The values at $p\text{H} = 6$ are shown in Fig 1

Two other pieces of evidence support this hypothesis Thus, Dainton and Peterson[3] showed that $G(N_2)$ from γ-irradiated aqueous solutions of N_2O undergoes an increase of about one unit as the pH is increased above 11 This was attributed to ionic dissociation of the OH radical, but this explanation is less free from objection than the simple assumption of the occurrence of either reaction (5) or reaction (6) Again, the existence of the acid-base reaction (16), which is closely related to reactions (5) and (6) and was first proposed by Baxendale and Hughes[5], has recently been unequivocally demonstrated[6]

$$H_{aq} + OH^-_{aq} \longrightarrow e^-_{aq} \qquad (16)$$

If H^+ and OH^- ions can each react with H_2O^* or (H + OH) it is to be expected that other solutes will exist which also have this property In fact aqueous solutions of some solutes at a pH within the range $3 < p\text{H} < 11$ on irradiation give a single product which seems to be derived from reaction of the solute with e^-_{aq} alone, while solutions of other solutes give products seemingly derived from reactions with both e^-_{aq} and H This situation is readily explicable A solute, such as nitrous oxide, may react rapidly with e^-_{aq} but only slowly with (H + OH) or H_2O^* and will therefore 'see' only e^-_{aq} Another solute may react rapidly with (H + OH) or H_2O^* as well as with e^-_{aq} but in reacting with the former generates a product which is converted back to the original reagent by the remaining radical of the radical pair Examples of this may be oxygen and $Fe(CN)_6{}^{3-\text{and}4-}$ when the relevant fast reactions are

$$H_2O^* \text{ or } (H + OH) + O_2 \rightarrow HO_2 + HO \rightarrow H_2O + O_2$$

$$H_2O^* \text{ or } (H + OH) + Fe(CN)_6^{3-} \rightarrow H_2O^+ \text{ or } H^+ + OH + Fe(CN)_6^{4-} \rightarrow H_2O + Fe(CN)_6{}^-$$

$$H_2O^* \text{ or } (H + OH) + Fe(CN)_6{}^{-4} \rightarrow H + OH^- + Fe(CN)_6{}^{-3} \rightarrow H_2O + Fe(CN)_6{}^{-4}$$

The solute in this case may be regarded as a quencher of H_2O^* or as a catalyst of H + OH recombination but in any event will only 'see' e^-_{aq} or OH There are yet other solutes which can react quickly with e^-_{aq} to form one product and with H_2O^* or (H + OH) to form another which is resistant to attack by the conjugate radical These will 'see' both e^-_{aq} and H_2O^* or (H + OH) An example is Cl CH_2COOH, which reacts with e^-_{aq} to form Cl^- ($G(Cl^-)$ at $4 < p\text{H} < 7 = \sim 3$) and with H_2O^* or (H + OH) to form H_2($G(H_2)$ at $4 < p\text{H} < 7 = \sim 1$)[4,7], which reacts only slowly with OH Such solutes should compete with OH^- ions for H_2O^* or (H + OH) and accordingly we expect that for several organic solutes $G(H_2)$ should decrease markedly around pH 11 and G (product derived from e_{aq}^-) show a complementary increase

CHEMISTRY

Complex Formation of Monomeric Amides with Lithium Perchlorate

It has been demonstrated that aqueous solutions of lithium bromide can induce the disruption of the ordered portions of fibrous and globular proteins[1-4] Since this phenomenon is observed for proteins of widely differing secondary and crystallographic structure and also amino-acid composition, the conclusion was reached that an interaction with the peptide linkage was involved The nature of the melting temperature–LiBr concentration curve for both α and β keratin[1,2] suggested that, in addition, an alteration in the nature of the peptide bond occurs

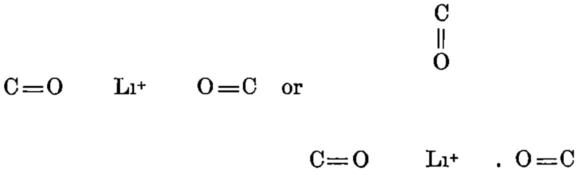
Lithium bromide and similar salts are known to form complexes with simpler compounds containing some of the characteristic features of the peptide groups[5-9] In particular, complexes of the general formula $LiX\ nCO(NH_2)_2$ with $n = 1$, 2, and 3 have been established for aqueous solutions of lithium bromide or lithium chloride with urea[7,8] A similar situation has also been demonstrated for aqueous solutions of lithium bromide with either *N*-methylacetamide or dimethylacetamide[9] Contrary explanations have been offered, and the interpretation of the results is complicated by the necessity of having a third component, water, present in the systems previously selected for study Since the melting of the fibrous proteins can also be demonstrated in non-aqueous solutions of lithium bromide[10], the examination of model compounds to elucidate the nature of the interaction is best accomplished by the elimination of water from the system

To this end we have investigated, by means of an infra-red spectroscopic technique, the interaction of anhydrous lithium perchlorate with *N* - methylpropionamide (NMP) Solutions of the anhydrous salt and NMP were prepared in a dry nitrogen atmosphere, the molar ratio of amide to lithium employed was approximately 3 1 This system, thus, possesses the advantage that adequate solubility of the salt in the amide can be obtained without the intervention of water

The spectral data for the pure amide and the solution are illustrated in Fig 1 A strong interaction between the lithium salt and the amide group is indicated Lithium bromide was found to give essentially the same results, so the effect can be attributed largely to the lithium ion The amide absorption band at 1 645 cm^{-1} attributed to C=O stretch (amide I) shows a marked change on addition of lithium perchlorate to the pure amide This carbonyl frequency is lowered in wave number, the single band observed with the pure amide (1,645 cm^{-1}) becomes a doublet (1,645 cm^{-1} and 1,620 cm^{-1}) The amide absorption band at 1,550 cm^{-1} attributed to N—H deformation coupled with C=N stretch (amide II) (ref 11), and its accompanying weaker absorption band (amide III), are slightly changed on addition of lithium perchlorate to the pure amide

The N—H stretching mode at 3,300 cm^{-1} of pure NMP is also significantly altered on addition of lithium perchlorate The strong band at 3,300 cm^{-1} is completely replaced by a strong band at 3,400 cm^{-1}, representing a change toward the higher frequency by 100 cm^{-1} In addition, the weaker NH vibrational band observed in the pure amide at 3,100 cm^{-1} becomes of even weaker intensity, almost to disappearance, in the lithium perchlorate–amide mixture

These results are strikingly similar to those obtained by Gerrard, Lappert, Pyzora and Wallis[12] in their investigation of the spectra of simple amides and the complexes that are formed with boron trihalides The results reported here can be interpreted in a similar manner The results suggest that the lithium ion interacts with the carbonyl group directly, rather than with the nitrogen atoms previously suggested for the urea complexes of lithium chloride[7] The splitting of the carbonyl frequency may be attributed to lithium to carbonyl bonding, the lithium ion being bonded perhaps to more than one carbonyl group



$$C{=}O \quad Li^+ \quad \overset{\overset{\displaystyle C}{\|}}{O}{=}C \quad \text{or} \qquad C{=}O \quad Li^+ \quad . \ O{=}C$$

A somewhat similar conclusion has recently been reached by Bello and Bello[13] from a preliminary

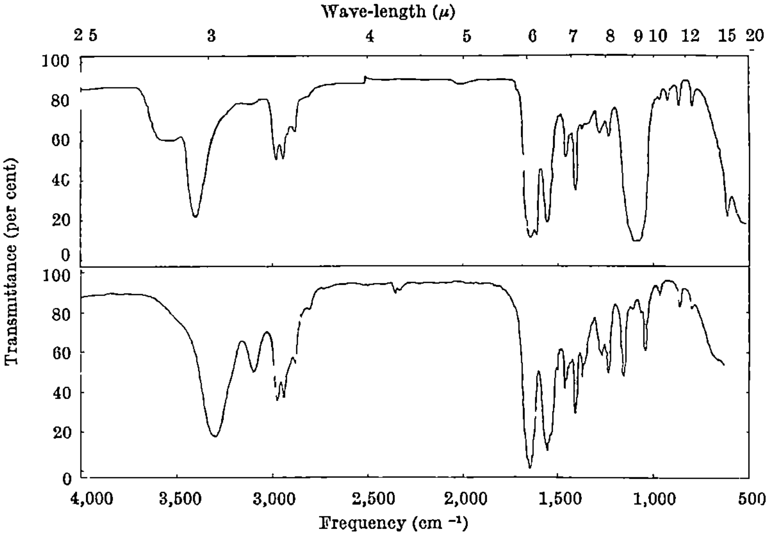


Fig 1 Upper curve, infra-red spectrum of pure *N*-methylpropionamide, lower curve, infra-red spectrum of anhydrous lithium perchlorate-*N*-methylpropionamide solution

structural analysis of the crystals precipitated from an aqueous solution of *N*-methyl acetamide and lithium bromide The formation of the polymeric forms of the amide would be consistent with the extremely high viscosity observed in the solutions[14] The disruption of the hydrogen-bonded network of the pure liquid amide, upon the introduction of the lithium ion, is consistent with the characteristic shift observed in the N—H stretching mode At the concentration of lithium perchlorate used, there is no spectral evidence of any residual interamide hydrogen bonds, indicating that essentially all the amide groups are bonded by means of the lithium ion

Studies in which small amounts of water were deliberately added to the system show that the splitting of the carbonyl band is observed only when the NMP–lithium perchlorate mixture is essentially free of water, as indicated by a very weak band at 3,600 cm^{-1} (O—H stretch) The presence of water will allow the lithium ion to form its hydration shell and thus reduce the effective concentration of lithium ion available for binding with the amide These results indicate that the disruption of the ordered structure observed in protein systems could very well be a result of a similar binding phenomenon not necessarily involving the water present

We thank Dr W G Bordum for supplying *N*-methylpropionamide, and Dr G Atkinson for helpful discussions

Differential Thermal Analysis of Potassium Perchlorate

Gordon and Campbell published a paper[1] in which the differential thermal analysis of potassium perchlorate is illustrated from the point of view of the characterization of this compound rather than the details of its decomposition In this work, where the differential thermal analysis was carried out in a test-tube in an open furnace, a large endotherm following the initial exotherm after fusion was observed Later, Markowitz and Boryta[2] became interested in the details of decomposition as revealed by differential thermal analysis and pointed out that this endotherm is due to the molten sample rising up the sides of the tube resulting in separation of the sample from the thermocouple This gives rise to an apparent endotherm at that point These authors attempted to overcome the thermal effects which accompany the separation of the sample from the thermocouple by carrying out the thermal analysis in a closed furnace system Although the endotherm in question is not observed under these conditions, the details of the decomposition are missed, undoubtedly due to the large mass of sample used in these experiments and because of poor heat transfer conditions in the closed furnace system The approach in conducting the differential thermal analysis experiments in the present work is to adjust the sample mass and dimensions of the sample container so that the decomposing gases will not force the reacting mass up the tube This results in intimate contact of the sample with the thermocouple throughout the entire reaction, which is after all the best condition for the differential thermal analysis experiment It was found that when 500 mg and less of potassium perchlorate are contained in test-tubes with a ninside diameter of 16 mm separation of the sample from the thermocouple does not occur These experiments show that it is possible to obtain detailed differential thermal analysis curves for decomposition reactions which are accompanied by violent foaming and bubbling by adjusting sample weight and geometric experimental parameters In this work the detailed differential thermal analysis curve for the decomposition of potassium perchlorate is presented for the first time, which reveals two exothermal processes one during decomposition prior to the precipitation of potassium chloride and the other which occurs simultaneously with the precipitation of potassium chloride This was determined in differential thermal analysis experiments carried out in a metal block previously described[1] where provisions were made for observing the sample as it was heated

Fig 1 shows the results of a combination of differential thermal analysis and thermogravimetric analysis carried out simultaneously on an 86 mg sample of potassium perchlorate The sample mass used in these experiments is over 50 times less than that used by the referenced authors This curve is essentially identical with the differential thermal analysis curves obtained with 500-mg samples using the furnace block The differential thermal analysis curve shows an endotherm due to melting with a peak at approximately 606° After melting the reaction becomes exothermal The exothermicity decreases as the temperature approaches approximately 638° At 638° a sharp rise in exothermicity occurs with a peak at 641° followed by the rapid decay of the exotherm The thermogravimetric analysis curve shows that weight loss due to decomposition occurs simultaneously with the endotherm for melting and is complete at the peak of the final exotherm The thermogravimetric analysis curve shows a single, smooth, sigmoidal-shaped weight-loss curve with no inflexions corresponding to the thermal changes which occur during the reaction Decomposition occurs throughout melting as well as the exothermal regions of reaction Prior to the final exothermal band at 638° the samples underwent 67 per cent decomposition Observations made in separate experiments show that after melting and during the first exothermal step of decomposition following melting the decomposing mass is clear

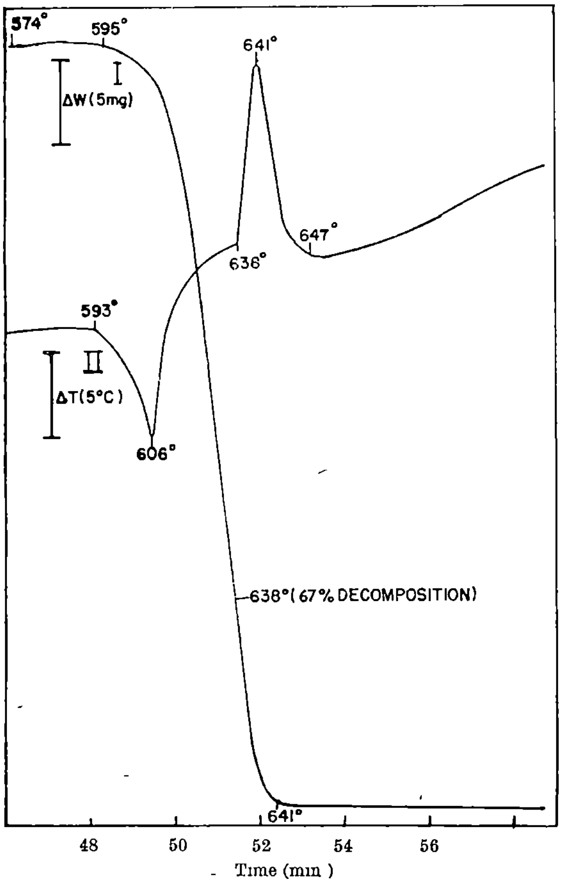

Fig 1 Simultaneous thermogravimetric analysis (I) and differential thermal analysis (II) curves for an 86-mg sample of potassium perchlorate heated in air at a rate of 10° C/min

The final exothermal band is observed to occur during the precipitation of potassium chloride Since the net decomposition of potassium perchlorate to form chloride liquid and oxygen is reported[2] to be endothermal the fact that an exothermal reaction occurs prior to 638° in the clear molten mass remains to be explained This is not easy since in spite of the fact that the decomposition of potassium perchlorate has been studied the mechanism of reaction is not well understood[3–5] The initial exotherm to 638°, however, is evidence that decomposition to KCl (liquid) is actually exothermic contrary to the previous belief that this reaction should be endothermal[2]

There were two series of differential thermal analysis experiments In the first series the apparatus which was previously described[1] consisted of a metal block in which test-tubes containing the samples and reference materials are located The metal block was heated at a rate of 10° C/min and the differential temperature vs sample temperature was recorded on a Moseley autograph, model 3 *X-Y* recorder A West Gardsman proportional controller was used to monitor the rate of heating In these experiments bare 28-gauge chromel–alumel thermocouples were located in the sample and reference materials The sample weight was approximately 500 mg and in both series of experiments doubly recrystallized Fisher scientific reagent grade potassium perchlorate was used The second series of experiments involved obtaining both the differential thermal analysis and thermogravimetric analysis curves simultaneously on about 86 mg of potassium perchlorate The apparatus used consisted of an analytical balance which was adapted for automatic recording by means of a linear differential transformer A rod which is supported on one end of the balance beam and which is in the vertical position above the balance is used to support sample and reference materials, which were contained in 16-mm test-tubes, approximately 1½ in long The sample and reference materials were mounted, one above the other Chromel–alumel, 38-gauge thermocouples were placed in both the sample and reference compounds The furnace was lowered over the test-tubes Changes in weight and differential temperature were recorded on a Bristol 2-pen time base recorder while sample temperature was simultaneously recorded on a Brown strip chart recorder The heating rate was programmed at 10° C/min In all cases replicate experiments were conducted

Gelatin as a Protective Colloid

It is well known that a solution of gelatin restrains the precipitation of most insoluble substances It has also been shown, in a study of the Liesegang phenomenon[1], that the gelatin composing a set gel exerts little or no restraint beyond eliminating mechanical mixing The experiments reported here suggest that gelatin solutions lose much of their restraining power before they set to gels

Two pure, inactive photographic gelatins were used, of which I had a shorter setting time and higher gel strength than II 200 ml of a 2½ per cent solution of gelatin containing 0 087 M potassium bromide was taken, and 2 ml of 0 300 M silver nitrate added to it (leaving an excess of 10 0 g/l potassium bromide) The solutions were stirred throughout and the growth of turbidity was followed by withdrawing samples at intervals and measuring the optical density to red light with a 'Spekker' photometer The lower the temperature the more slowly did the turbidity increase Below about 28°, however, a proportion of the silver bromide was precipitated immediately, as fairly large crystals, although the subsequent growth of density appeared normal Moreover, if the solutions were mixed at 43° C and then cooled to 26° C, the rate of growth of density was smaller than at high temperatures, as would be expected The lower the temperature of mixing, the more silver bromide was precipitated immediately so that the time needed to reach a fixed density fell rapidly This is shown in Fig 1, where the logarithm of the time needed to reach a density of 0 5 is plotted against the temperature of precipitation Gelatin II behaved similarly except that the break occurred at a slightly lower temperature A similar loss of restraining power was observed when potassium bromide was added to a large excess of silver nitrate in gelatin The phenomenon was not related to the onset of gel formation since a solution of 0 2 per cent of gelatin I also behaved in the same way (Fig 1), although it was too dilute to form a gel, even at 1° C

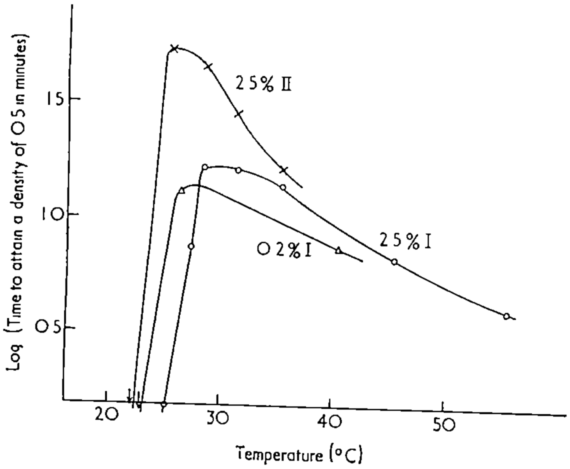

Fig. 1. Logarithm of the time needed to attain a density of 0·5 as a function of temperature

The break-down in protection is probably associated with the formation of aggregates of gelatin molecules, which Boedtker and Doty[2] showed to form in this temperature-range, even when the solution was too dilute to gel. Presumably the aggregates are unable to adsorb on the freshly forming precipitate quickly enough to afford protection in the initial stages of precipitation. Once adsorbed, however, they afford colloid protection and the later stages of ripening appear to be normal.

Optical Properties and Structure of Crazes in Transparent Glassy Polymers

It has been known for about a year that a large fraction of what appear to be planar reflective cracks in transparent polymers such as polystyrene, polymethyl methacrylate, and polycarbonate are not true cracks at all but rather are thin, abruptly bounded regions of material having different optical properties from the bulk polymer[1]. This material connects to the surrounding bulk polymer so that the pseudo-crack (henceforth termed a craze) will bear a tensile load in contrast to the true crack. Furthermore, such things as growth-rates under stress and ability to 'heal' under heat are quite different for the craze and the crack. Nevertheless, crazing produces stress heterogeneities, and for this reason at least is a precursor of cracking and fracture.

For reasons such as these it is obviously of importance to be able to differentiate between crazes and cracks and to know the details of craze structure and properties. Recently a way has been found here to measure quickly, conveniently and non-destructively the refractive index of the crack or craze *in situ*. From the index it is possible to differentiate between cracks and crazes and to obtain a great deal of information about the latter.

The method of index determination (Fig. 1) involves measuring the critical incident angle of a parallel light beam on the polymer specimen surface for which total internal reflexion occurs at the interface between the craze or crack and the bulk polymer. The beam, upon entering the specimen, is refracted to a new angle which is calculable knowing the refractive index of the bulk material. That portion of the beam which strikes the craze interface either is transmitted and passes on out the back side of the specimen or suffers total reflexion, whereupon a shadow of the craze appears on the back side. With the various angles involved and the bulk polymer index known, the craze or crack index is calculable from Snell's law of refraction. It is easily shown from Snell's law also that the calculations are not affected by the possible presence of thin layers of material of different index from the bulk either at the specimen surface or at the craze-bulk interface. (Such layers, for example, could arise from orientation or swelling effects.) It should also be stated here that for cracks or crazes of low index the incident angle on the craze-bulk interface cannot be made large enough with the set-up in Fig. 1 for light to be passed by the craze, due to the geometry of the system. This limitation was overcome by affixing 30° polymer wedges with flat polished faces on the front and back specimen surfaces with a suitable transparent adhesive ('Apiezon' grease works well.) The wedges were placed in such a way that their outward faces were at 60° to the craze plane whereas the former polymer–air surfaces were at 90° to the craze. This addition allowed high-incident angles at the craze plane and observance of shadow disappearance through the back wedge.

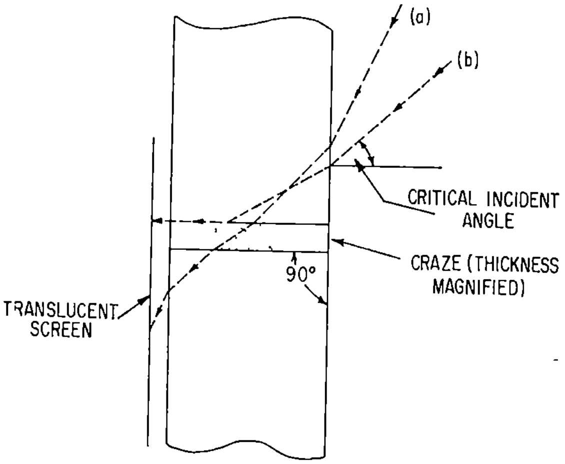

Fig. 1. Cross-sectional diagram of set-up for measuring critical angle for total reflexion at craze interface. Incident angle of parallel beam (*a*) is large enough for beam to pass through craze and register on screen. Beam (*b*) is at the critical angle and a shadow of the craze appears on the screen

Under favourable conditions critical incident angles can be determined by the naked eye to ± ½° with practice. It is also noteworthy that within these limits of accuracy at least the critical angle has not appeared to change with polarization of the incident beam. Finally, although the craze is generally thin enough to give rise conceivably to interference effects, none has been noticed during the measurements of critical angles.

Results with polycarbonate. To date investigations have dealt with 'Lexan$^{(R)}$' (General Electric Co. trademark) polycarbonate resin. The material commends itself for craze structure study because single planar crazes of large size (both in thickness and planar dimensions) can be produced by subjecting specimens to moderate bending strains under poorly plasticizing liquids such as n-C_6H_{14} or C_2H_5OH. On the other hand, large true mirror-smooth cracks may be propagated into specimens by judicious bending under carbon tetrachloride

Initially cracks induced by carbon tetrachloride give $n = 1\ 44$, the index of CCl_4 liquid Within a few minutes exposure to air the liquid in the crack evaporates out and n drops to 1 00, the index of air These results are a check on the method Polycarbonate crazes, on the other hand, yield widely varying indices depending on post-crazing treatment of the specimen Some results for ethanol-induced crazes follow

For a freshly produced craze $n = 1\ 46$, which is between that of the bulk polymer (1 58) and liquid C_2H_5OH (1 36) If the applied stress and the alcohol environment are both removed a healing process appears to occur over several days, the index rising eventually to 1 57 The rise appears to be linear on a log time plot, suggesting the occurrence of a disorientation process On the other hand, if the specimen is left strained after its removal from the alcohol, the index begins to drop rapidly and finally reaches a value of 1 27 Investigations of the kinetics here suggest that a rather rapid diffusion of alcohol back out of the craze is occurring, leaving a porous structure behind

Assuming polarization additivity on a weight fraction basis, volume additivity for polymer–alcohol mixtures, and a negligible effect of orientation on the specific polarizability of the polymer, it is possible to calculate craze density and composition from the Clausius–Mosotti equation[2] The only quantities needed are the craze indices and the indices and densities of the pure components (Polycarbonate density is 1 20 g/cc) On this basis the fresh, alcohol-saturated craze appears to be 40 per cent alcohol–60 per cent polymer by volume The still-strained, dried-out craze is calculated to be 50 per cent air–50 per cent polymer assuming no alcohol remains The two calculations are thus in reasonable agreement

The value of 60 per cent polymer content in the craze is buttressed by photomicrographs of the craze at the specimen surface It is found that suitable scratches imposed on a specimen prior to crazing are distorted when a craze developed across them, from the craze width and the scratch distortion it is calculated that a unit of material in the craze at the specimen surface is about 40 per cent longer than it was before crazing Although lateral contraction (that is, reduction in the dimensions of the craze plane) takes place in the craze at the specimen surface, the resultant volume contraction is negligible compared to the volume increase due to elongation in the stress direction upon craze formation The result is a polymer density decrease by 40 per cent The normal solubility of ethanol in polycarbonate is 8 per cent, so that the remainder of the rarefaction must be attributed to 3-dimensional tensile stresses existent in craze formation In this respect at least crazing differs from cold drawing, which appears to involve elongation by shearing at 45° to the tensile stress[3] with no resultant change in material density (unpublished observations on cold drawing of polycarbonate)

BIOCHEMISTRY

Isoxazolyl Penicillins and Penicillinase

THE isoxazolyl series of penicillinase-resistant penicillins has been described by Doyle *et al* [1] Many members of this series are acid-stable, and considerably more active against staphylococci than methicillin Three members of this series (*BRL* 1400 5-methyl-3-phenyl-4-isoxazolylpenicillin, *BRL* 1577 5-methyl-3-*p*-chlorphenyl-4-isoxazolylpenicillin and *BRL* 1621 5-methyl-3-*o*-chlorphenyl-4-isoxazolylpenicillin) have been investigated for antibacterial activity and for stability to, induction of, affinity for, and inhibitory action on, the penicillinases of *Staph aureus* and *B cereus*

Most of the cultures used were freshly isolated from clinical material, but in some cases stock strains were used 0 01 ml of a 1/10 dilution of a 6-h infusion broth culture was inoculated on to penicillin-containing infusion agar The plates were incubated overnight and the results recorded The results (Table 1) show that penicillin *G* was highly active against the Oxford staphylococcus and the other penicillinase-negative strain whereas the isoxazolyl penicillins were about 10 times less active Methicillin was even less active, having only about a fifth to a tenth of the activity of the isoxazolyl penicillins.

Table 1 MINIMUM INHIBITORY CONCENTRATIONS (μG/ML) OF PENICILLINS AGAINST *Staph aureus* STRAINS

Staph aureus	Penicillinase	Penicillin *G*	Methicillin	*BRL* 1400	*BRL*.1577	*BRL* 1621
Oxford	−	0 025	0 9	0 2	0 2	0 2
A 8	−	0 02	1 8	0 2	0 2	0 2
A 9	+	3 7	1 8	0 2	0 2	0 2
A 6	+	6 2	1 8	0 4	0 2	0 4
A 14	+	15	1 8	0 2	0 2	0 2
A 7	+	15	1 8	0 4	0 4	0 4
A 13	+	62 5	3 7	0 9	0 4	0 4
Cave	+	62 5	3 7	0 9	0 4	0 4

E 3	+	250	3 7	0 9	0 9	0 9
Hunter	+	250	3 7	0 9	0 9	0 9

Penicillinase positive staphylococci, however, were all relatively resistant to penicillin *G* Methicillin was at least twice, and at the most 67 times, as active as penicillin *G* The isoxazolyl penicillins were about 5 times as active again as methicillin against these penicillinase-producing strains The question of cross-resistance between methicillin and the isoxazolyl penicillins will be discussed elsewhere

BRL 1621	1 1	0 3

The breakdown of the various penicillins by penicillinases from *Staph aureus E*3 and *B cereus* N R R L 569 was measured by the hydroxylamine method of Boxer and Everett[2] as described by Knox and Smith[3] The results (Table 2) show that methicillin is the most resistant penicillin to staphylococcal penicillinase, being broken at 0 7 per cent of the rate of penicillin *G* The isoxazolyl penicillins, however, were less resistant to staphylococcal penicillinase than methicillin, being destroyed at about twice its rate, although the difference may not be significant With the *B cereus* penicillinase, however, both *BRL*. 1621 and *BRL* 1577 were more resistant to hydrolysis than methicillin although *BRL* 1400 was hydrolysed more readily than methicillin

The initial rate of destruction of each penicillin at various concentrations was measured by the hydroxylamine method[2] and the Michaelis constants (K_m values) were calculated by the method of Lineweaver and Burk[4]. Manson *et al.*[5] found that the K_m for penicillin *G* and the extracellular enzyme of *B. cereus* was approximately 20 μg/ml., and Novick[6] found that the K_m for penicillin *G* and the cell-bound enzyme of *Staph. aureus* was about 7 μg/ml. The K_m values determined here for the isoxazolyl penicillins and methicillin (Table 3) are about a thousand-fold larger than these values.

Table 3. MICHAELIS CONSTANTS OF VARIOUS PENICILLINS IN MG/ML.

Penicillinase	Penicillin			
	Methicillin	*BRL*.1400	*BRL*.1577	*BRL*.1621
Staph. aureus	7·7	5·9	6·5	*
B. cereus	5	16	13	10

* Concentrations of this penicillin greater than 3 mg/ml. showed no appreciable hydrolysis, hence the Michaelis constant could not be determined.

The concentration of penicillin necessary to cause half maximal and maximal induction of penicillinase above the basal value was determined as described by Knox and Smith[3] using *Staph. aureus E*3. The results (Table 4) show that although methicillin was much more active than benzyl penicillin, the isoxazolyl penicillins were even more active as regards the amount necessary to cause half-maximal and maximal induction. In addition, the increase in penicillinase content of fully induced cells was highest with the isoxazolyl penicillins. The figures given for penicillin *G* are probably of little significance since this inducing agent is destroyed during induction.

Table 4. INDUCING ABILITY OF THE VARIOUS PENICILLINS UPON THE PENICILLINASE OF *Staph. aureus E* 3

	Concentration μg/ml. to give maximal induction	Concentration μg/ml. to give half-maximal induction ('induction constant')	Ratio of induced to basal penicillinase activity at maximum
Penicillin *G**	300	6·6	12·4
Methicillin	3	0·27	36·0
BRL.1400	0·3	0·019	55·8
BRL.1577	0·3	0·017	65·8
BRL.1621	0·1	0·013	71·3

* See text.

The amount of inhibition caused by methicillin and the isoxazolyl penicillins was measured by using a modified form of the method of Saz, Lowery and Jackson[7]. The hydrolysis of 1 mg/ml. of penicillin *G* in the presence of 1 mg/ml. of the 'inhibitor' penicillin added simultaneously to the enzyme was followed at 37° C. As it was found that a given amount of inhibitor caused more inhibition as the enzyme concentration was decreased, the enzyme preparations used in these studies were adjusted so that they hydrolysed penicillin *G* at approximately similar rates (2 μg/min). No inhibition occurred using the staphylococcal enzyme, but it has been shown[8] that previous incubation of staphylococcal penicillinase with methicillin or *BRL*.1400 caused some inactivation. With the *B. cereus* enzyme methicillin inhibited the hydrolysis of penicillin *G* by 67 per cent and the isoxazolyl penicillins inhibited the hydrolysis of penicillin *G* by 29 (*BRL*.1400), 22 (*BRL*.1577) and 23 (*BRL*.1621) per cent.

The efficacy of methicillin, the first penicillin highly active against penicillinase-producing staphylococci, seemed, partly at least, to be due to its high degree of resistance to staphylococcal penicillinase. The isoxazolyl penicillins were found to be slightly less resistant to staphylococcal penicillinase than methicillin and both the isoxazolyl penicillins and methicillin had similar low affinities (high K_m values) for staphylococcal penicillinase as compared with the high affinity (low K_m) of penicillin *G*. Neither methicillin nor the isoxazolyl penicillins inhibited the hydrolysis of penicillin *G* by staphylococcal penicillinase, although they did inhibit *B. cereus* penicillinase. Thus the fact that the isoxazolyl penicillins were more active than methicillin against penicillinase-producing staphylococci could not be explained in terms either of stability to staphylococcal penicillinase or of affinity for the enzyme. However, the isoxazolyl penicillins were much more effective than methicillin in inducing staphylococcal penicillinase, giving low induction constants[9] suggesting high inducing affinity.

We acknowledge gifts of methicillin and the isoxazolyl penicillins from Beecham Research Laboratories and technical assistance from Miss B. Whittamore.

Hepatotoxic Action of Chromatographically Separated Fractions of *Aspergillus flavus* Extracts

THE presence in certain groundnut meals of a toxic substance which causes the death of young ducks and turkeys has recently been reported[1]. The toxin is produced by a strain of the mould *Aspergillus flavus* growing on the groundnuts[2,3]. There are two methods for detecting this substance: a biological test with ducklings and a chemical test in which a single, blue fluorescent spot is found on paper chromatograms of extracts of the mould or mould-infected meals. By chromatographing extracts of toxic strains of *A. flavus* on thin layers of silica-gel we have obtained at least twelve fluorescent components, five of which caused liver lesions when fed to ducklings.

Cultures of *Aspergillus flavus* were grown on a glucose-ammonium nitrate medium[4] in penicillin flasks. After 9 days at 27° C the mould was separated from the growth medium by filtration and shaken with chloroform to give a yellow-coloured extract. The growth medium was also extracted with chloroform in a liquid-liquid extractor and the combined extracts were evaporated to a small bulk under nitrogen gas to give a concentrate (about 2·0 mg/ml. total solids) suitable for preparative chromatography on thin layers of silica-gel.

A 275-μ thick layer of 'Kieselgel *G*' (Merck) was applied to glass plates with a Desaga spreader. These plates were dried at 105° C for 24 h and stored in an open rack; they were re-heated to 105° C for 1 h immediately before use. To separate material for duckling feeding experiments, replicate spots (5–10 μl.) of the chloroform extracts were suitably spaced

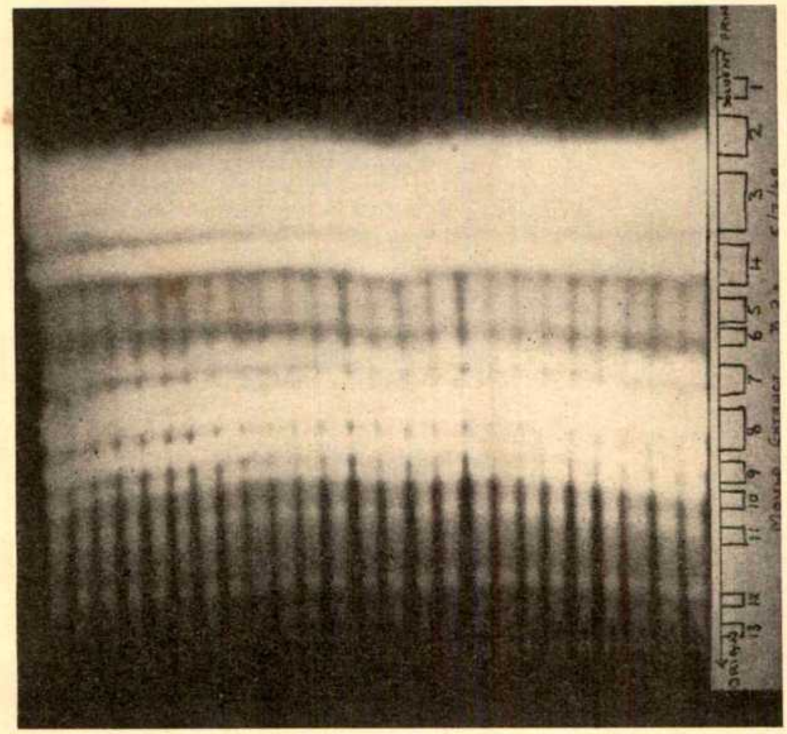

Fig. 1. Preparative thin-layer chromatogram of extract of toxic strain of *Aspergillus flavus*, photographed under ultra-violet light

along a starting line parallel to one edge of a 20 × 20 cm plate and chromatographed by the ascending method in small glass tanks equilibrated with chloroform/methanol/formic acid (95 : 5 : 1); separation took about 30 min.

Extracts of highly toxic strains of *A. flavus* were thus resolved into at least 12 clearly defined components which fluoresced under ultra-violet light (365 mμ). In Fig. 1, a typical preparative plate, the fluorescent components have been numbered in decreasing R_F order. Components 3 and 4 together account for about 60 per cent of the total fluorescence of applied extract. Components 4 and 9 had a blue-green fluorescence, in contrast to the dark blue fluorescence of the other spots. If the chromatogram was sprayed with 50 per cent sulphuric acid and gently warmed, the colour of the fluorescence changed from blue to yellowish-green. At the same time the more strongly fluorescent components became visible under ordinary light as yellow spots, which on stronger heating (200–250° C) became dark blue in colour. Under these conditions the rather weakly fluorescent components 1 and 2, running near the solvent front, first gave a characteristic rose-pink colour and on stronger heating a dark brown colour.

For biological testing the individual fractions were isolated by scraping the band of adsorbent associated with each row of fluorescent spots into a small beaker, extracting with chloroform and evaporating the extract to dryness under vacuum. When these fractions were rechromatographed in the same system, each gave essentially two components, one with the same R_F as the original spot and some fast-moving material, presumably fractions 1 or 2, which stained pink with sulphuric acid. Repeated thin-layer chromatography gave fractions which were substantially homogeneous. Fractions 10, 11 and 12, which were present only in small amounts, were not isolated.

Weighed amounts of the isolated components were suspended in water for administration to ducklings. Day-old Khaki-Campbell ducklings were fed 1 ml. of these suspensions per day for 5 consecutive days.

They were killed after 7 days and their livers examined histologically by Wannop's method[5]. Characteristic lesions, similar to those reported by Wannop[5] for turkeys with *X* disease, were observed in livers taken from birds fed fractions 3, 4, 5, 8 and 9. So far as could be judged by this histological test, all these fractions had about the same potency. Fractions 1, 2, 6 and 7 fed at the same level did not produce significant liver lesions.

Extracts of mildly toxic strains of *A. flavus* gave simpler chromatographic patterns in which component 3 or components 3 and 4 predominated (Fig. 2).

We conclude that the hepatotoxic activity of certain strains of *A. flavus* is associated with several discrete, fluorescent substances. With other methods of separation, this activity may prove to be even more complex in nature.

We thank Mr. P. Austwick, Central Veterinary Laboratory, for supplying the toxic strains of *A. flavus*; Mr. C. C. Wannop, Houghton

Radiometric Assay of Acetylcholinesterase

A METHOD for the microdetermination of acetylcholinesterase activity has been developed in which the formation of acetic acid labelled with carbon-14, liberated enzymically from the labelled substrate, is measured by a simple counting technique. The method has the advantage that it can be applied to very small samples of tissue at relatively constant *p*H. It has been applied successfully to samples of the order of 1 μl. of whole blood, blood plasma, or insect tissue deposited on cavity-type microscope slides. Since dilution of the sample is unnecessary or readily limited without affecting sensitivity, the technique provides a more reliable indicator of reversible cholinesterase inhibition by compounds such as carbamates than the conventional Michel method[1], for example.

Anhydrous sodium [1-^{14}C] acetate (6.8 mg containing 1 mc. carbon-14) was heated for 24 h at 60° C in a small sealed tube containing 0.47 ml. (5 mM) acetic anhydride. Complete isotope exchange between acetate and anhydride carboxyl occurred under these conditions (cf. Avivi *et al.*[2]). The [^{14}C]-acetic anhydride so produced was distilled *in vacuo* into a second small tube containing 139.7 mg [1 mM] of dried choline chloride, the tube sealed and complete acetylation achieved by heating the solution obtained for 1 h at 100° C as indicated by Cline[3]. The excess of [^{14}C] anhydride and free [^{14}C] acetic acid formed were recovered *in vacuo*, and the [1-^{14}C] acetylcholine washed in ether, weighed, dissolved in water and stored at −15° C until required for use as substrate. Radiochemical yield of the acetylated product was theoretical in terms of choline and sufficient for some 25,000 enzyme assays.

After incubation of the enzyme preparation and labelled substrate under the required conditions a small sample (1–5 μl.) is deposited on a 10-mm cavity microscope slide and 5 μl. of 0.5 N hydrochloric acid immediately admixed. The mixture is then dried in a vacuum desiccator, gently warmed in air for a few seconds and counted for carbon-14 activity under a thin end-window Geiger–Muller tube in the conventional way, geometry being carefully standardized. Under these conditions free [^{14}C] acetate is completely volatile while activity of carbon-14 due to the unhydrolysed acetylcholine is not. Control assays in which the enzyme is absent or known to be inhibited (for example, by 10^{-3} M eserine sulphate) are made simultaneously. The difference in counting rates between active and control samples therefore represents the free acetate resulting from enzymic hydrolysis of the substrate. Alternatively, enzyme samples and substrate may be mixed directly on the microscope slide and incubated in a moist atmosphere. The method can be applied to samples containing weights of substrate of the order of 1 μg. Weights of about 1 mg are required for the conventional Warburg manometric or ΔpH techniques[4].

An error would arise if the labelled acetate liberated enzymatically were further metabolized or underwent isotopic exchange with the formation of labelled metabolites which were not volatile on drying in the presence of hydrochloric acid. For example, [^{14}C] acetate is rapidly metabolized by the adult housefly *in vivo* with the formation of labelled amino-acids, protein, etc.[5] However, tests with diluted cholinesterase-active housefly head tissue extracts (1–2 heads per ml.) showed that all residual carbon-14 activity became acid volatile on pretreatment with 0.1 N sodium hydroxide at room temperature. Cholinesterase activity determined by the method was not significantly affected by the presence of 10^{-3} M cyanide, which would be expected to suppress any oxidative metabolism of free acetate. These observations indicate that residual carbon-14 activity was due entirely to unhydrolysed [^{14}C] acetylcholine and not due to labelled metabolites.

Repression of β-Galactosidase Synthesis by Amino-Acids in Thymine-starved *Escherichia coli*

THE ability to synthesize β-galactosidase of thymine-less mutants of *Escherichia coli* has been shown to be retained for a prolonged period of thymine starvation even when most of the starved bacteria have lost the viability[1,2]. These observations were obtained by inducing the thymine-starved bacteria in energy-deprived media. When the induction was carried out in the presence of an energy source, such as glycerol, the ability to synthesize β-galactosidase of the thymine-starved cells declined proportionally as the decline in the viability[2]. During the prolonged thymine starvation catabolites derived from the carbon source should have accumulated within the cells. On the subsequent induction with glycerol, these accumulated catabolites should exert 'catabolite repression'[3] on the synthesis of β-galactosidase, which is a catabolic enzyme.

In a previous report[2], it was demonstrated that the longer the duration of the thymine starvation the more rapidly enzyme was made by the starved cells in the induction medium deprived of glycerol. On the contrary, when a medium enriched with casamino-acids was used for the induction in an independent experiment[4], the thymine-starved cells showed a decreased rate of enzyme synthesis even in the absence of glycerol This communication describes the repressive effect of casamino-acids on the β-galactosidase synthesis in thymine-starved cells

E coli 15 *T-PA-* (thymine- and phenylalanine-less)[5] was grown and then starved for thymine in a mineral salts–glycerol medium at 37° with necessary growth factors as described previously[2] Cells which had been subjected for varying times to the thymine starvation were washed and suspended in two kinds of induction media One was a mineral salts medium without glycerol containing 0 001 M methyl-β-D-thiogalactopyranoside (TMG) and 0 0001 M L-phenylalanine The other was the same medium enriched with 500 μg/ml casamino-acids (Difco, certified) L-[1-^{14}C]-Leucine (specific activity 5 15 m c /m mole, New England Nuclear Corp , Boston, Mass) was added at zero time to give a final concentration of 15 μM together with non-radioactive L-leucine (0 0002 M, which is about equal to the L-leucine concentration in the medium enriched with casamino-acids) The non-radioactive leucine was not added to the enriched induction medium During the induction 1 and 2 ml aliquots were withdrawn at different time-intervals for the assay of β-galactosidase[6] and for the measurement of L-[1-^{14}C]-leucine incorporation into the protein of the cells[7], respectively In both induction conditions in the absence of glycerol, no net increase of total protein was observed Thus, the differential rate of enzyme synthesis during a given time of induction was calculated as follows

$$\frac{\Delta\text{Units } \beta\text{-galactosidase synthesized/ml}}{\Delta\text{Counts/min L-[1-}^{14}\text{C]-leucine incorporated/ml protein}}$$

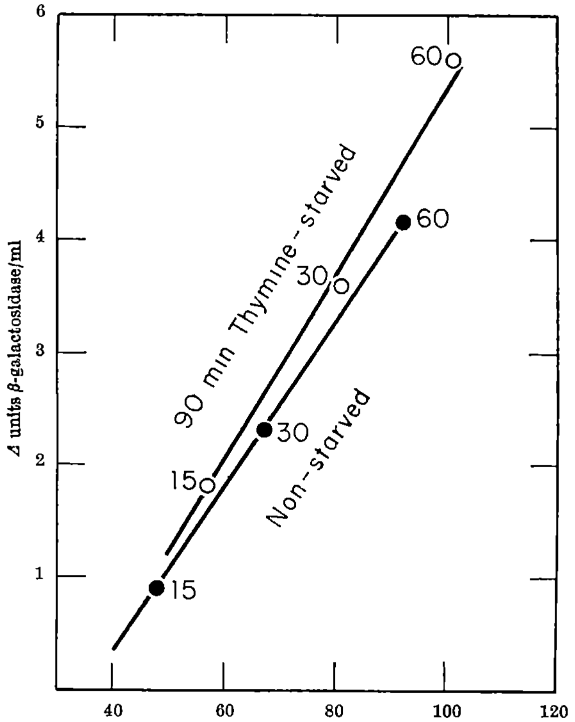

Fig 1 The differential rate of β-galactosidase synthesis by thymine-starved and non-starved *E coli* 15 *T-PA-* in induction media without casamino-acids Numbers in the figure indicate the induction period in min After 90 min starvation for thymine the viability was 3 7 per cent

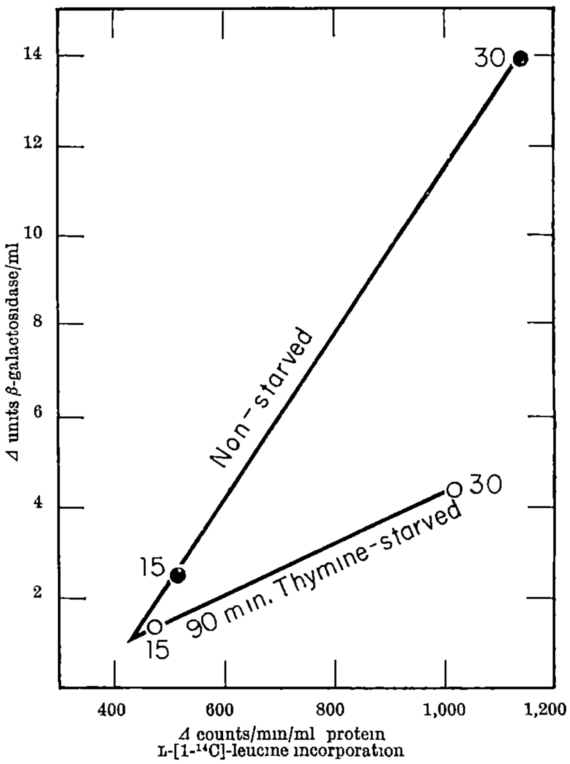

Fig 2 With casamino-acids (*see* legend to Fig 1)

A typical experiment is illustrated in Figs 1 and 2 In the induction medium without casamino-acids, the cells which had been starved for thymine for 90 min synthesized in the same time-interval more β-galactosidase than the non-starved cells The differential rate of enzyme synthesis was essentially the same in both starved and non-starved cells (Fig 1) On the other hand, in the induction medium enriched with casamino-acids a marked decrease of the differential rate of enzyme synthesis was observed in the cells starved for 90 min The amount of enzyme formed in the same time-interval by the previously starved cells was also markedly less than that by the non-starved cells (Fig 2) Some of the amino-acids supplied in the casamino-acids can presumably be metabolized by the cells to produce energy Thus in the previously thymine-starved cells, where the rate of protein synthesis is slow, the catabolites produced by the degradation of the amino-acids accumulate in the cell and repress the induced synthesis of the catabolic enzyme, β-galactosidase

Table 1 DIFFERENTIAL RATE OF β-GALACTOSIDASE SYNTHESIS BY *E coli* 15 *T-PA-* WHICH HAVE BEEN STARVED FOR THYMINE FOR VARYING TIMES

Thymine starvation before induction (min)	Viability (%)	Differential rate of β-galactosidase synthesis*, per cent retained	
		Induction without casamino-acids	Induction with casamino-acids †
0	100	100	100
30	120	106	107
60	13 6	92	51
90	4 1	112	36
120	0 5	101	12

* See text, expressed in per cent of the value obtained by the non-starved cells The values were taken between 15 and 30 min of induction During that time both enzyme synthesis and L-[1-^{14}C]-leucine incorporation showed linear increases

† Induction with casamino-acids generally gave a greater amount of enzyme synthesis than without casamino-acids though the differential rate of enzyme synthesis was smaller

The effect of amino-acids on β-galactosidase synthesis after different periods of thymine-starvation is presented in Table 1 Thymine-starved cells taken at varying times of the thymine starvation did not show any significant change in the differential rate of enzyme synthesis upon induction without casamino-acids, while with casamino-acids they did show a decline proportionally to the duration of the prior thymine starvation

This communication together with the previous reports indicate that the DNA after thymine starvation is good enough to act as primer for further synthesis of DNA when thymine is added back[8], and to give information for the synthesis of new species of protein The cause of the 'thymine-less death', however, is still obscure

Functional Alteration in the Prothrombin Molecule

PROTHROMBIN is the central protein involved in the blood-clotting mechanisms, and is of great importance in normal physiological functions From the point of view of health ordeals, reduced activity is associated with hæmorrhagic diseases and excess with thrombosis As a consequence knowledge about this molecule is of special importance Prothrombin has been isolated from plasma[1], and is the source of two enzymes, namely, thrombin, which clots fibrinogen, and autoprothrombin *C*, which catalyses the activation of prothrombin[2] In addition to these two enzymes at least three intermediates of prothrombin activation are known and have been called autoprothrombin I (ref 3), autoprothrombin II (ref 4) and prothrombin-*R* (ref 5)

Chromatography of the purified prothrombin of Seegers[1] on DEAE cellulose alters the structure of the molecule with respect to the C-terminal amino-acid composition[6] Glycine and tyrosine were found and after chromatography it was serine The *N*-terminal amino-acid alanine was not changed We have now made further comparisons of the original purified prothrombin and the DEAE chromatographed material The latter yielded essentially only thrombin as the end-product of activation whereas the former yielded the two enzymes thrombin and autoprothrombin *C* Furthermore, non-chromatographed prothrombin was added to factor *X* (Stuart–Prower) 'deficient' plasma and prothrombin utilization followed even though the original plasma contained prothrombin which was not consumed However, this prothrombin consumption was not found when the prothrombin was chromatographed on DEAE cellulose before it was added to the deficient plasma nor was it possible to elute anything active from the cellulose column As a consequence of these facts we think that factor *X* does not exist as a separate clotting entity Factor *X* 'deficient' plasma most likely has a prothrombin molecule that is functionally abnormal, much like the DEAE-cellulose chromatographed prothrombin From this point of view Stuart–Prower hæmorrhagic disease is a molecular disease To get prothrombin consumption in the plasma there must be a potential source of autoprothrombin *C*, and since the DEAE cellulose prothrombin does not supply this we are inclined to think that the prothrombin in the Stuart–Prower plasma does not readily yield this enzyme either

In our experiments we prepared the DEAE-chromatographed prothrombin[7] and dissolved it in a 25 per cent (w/v) sodium citrate solution Under our conditions no thrombin activity generated in 12 hr even when some purified thrombin was added at zero time as a catalyst We then added some autoprothrombin *C*, prepared according to procedures previously described[2], and were able to get thrombin rapidly with the use of this catalyst When this thrombin generated from the DEAE-cellulose chromatographed prothrombin there was practically no autoprothrombin *C* produced (Fig 1) such as occurs when non-chromatographed prothrombin is activated in sodium citrate solution[2] From previous work[6] we know that after chromatography on 'Amberlite *IRC*-50' there is no change in *C*-terminal amino-acids and the molecule activates in sodium citrate solution to yield both enzymes[2]

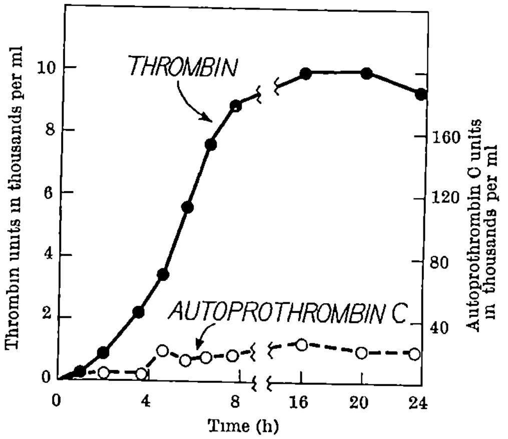

Fig 1 Activation of DEAE cellulose prothrombin in 25 per cent sodium citrate solution at 28° C The prothrombin was dissolved in 25 per cent sodium citrate solution to a concentration of 12,000 U /ml Autoprothrombin *C* (12,000 U /ml) was added at zero time to start the activation Thrombin and autoprothrombin *C* generation was followed

We examined other activation mediums besides 25 per cent sodium citrate solution With tissue extracts, Ac-globulin, and calcium ions, or with 'Stypven' (Russell viper venom, Burroughs Wellcome and Co), Ac-globulin, lipids and calcium ions we were not able to obtain autoprothrombin *C* from DEAE-chromatographed prothrombin These two procoagulant combinations are precisely the ones to which the prothrombin in Stuart–Prower-deficient plasma is resistant The prothrombin of Stuart–Prower plasma does not activate readily in the 2-stage analysis if tissue extracts are used as procoagulant or if 'Stypven' with lipids is used, but activates rapidly with a combination of autoprothrombin *C* and lipids We found the same to be true for DEAE-chromatographed prothrombin. In normal plasma, or in the purified but not chromatographed prothrombin preparations, prothrombin activates rapidly with the 2-stage analytical reagents irrespective of which procoagulant is used.

So far as we know the prothrombin of Stuart–Prower-deficient plasma has not been isolated to see whether it yields autoprothrombin *C*, and there are technical difficulties owing to the limited supply of blood. We are also not aware of any attempt to use purified prothrombin as a therapeutic agent in Stuart–Prower cases. Meanwhile we could try to see which one of our purified prothrombin preparations, if any, would give prothrombin utilization when added to the deficient plasma, and found that the one which can yield autoprothrombin *C* does so while the other one does not.

In our prothrombin utilization studies we used the original method of Brinkhous[8] with the exception that purified autoprothrombin *C* served as the procoagulant in the 2-stage prothrombin analysis in place of tissue extracts. This modification was introduced because Stuart–Prower plasma seemed to contain only 50 u. of prothrombin/ml. when tissue extract was the procoagulant whereas it in fact contained 235 u. when autoprothrombin *C* was used as procoagulant (Fig. 2). The prothrombin utilization of the Stuart plasma was slow and incomplete. This was not improved with the addition of DEAE-chromatographed prothrombin, which is the functionally altered molecule. On the other hand, prothrombin utilization was rapid when purified prothrombin was added. For example, after a delay of 5 min. the prothrombin concentration dropped from 255 to 25 u./ml. in 15 min. (Fig. 2).

As a consequence of considering the facts related to our experiment we offer as our preferred interpretation that Stuart–Prower 'deficient' plasma contains an abnormal prothrombin molecule and that the defect is a molecular disease. This view can be incorporated with the known observations about the genetics involved[9]. The factor *X* which is supposed to be lacking in this plasma really does not exist. It may be that fractions of plasma obtained in different laboratories and which are supposed to have factor *X* activity actually contain autoprothrombin *C*.

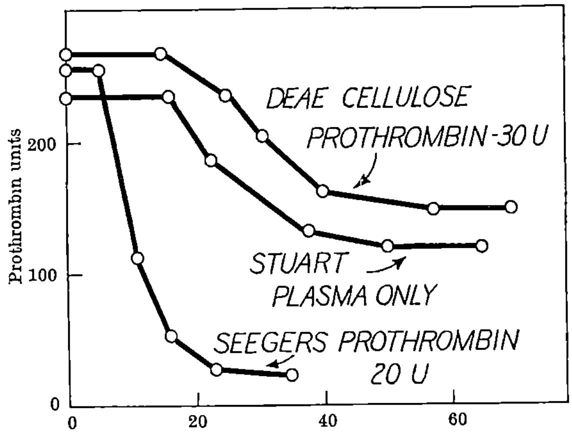

Fig. 2. Prothrombin consumption in Stuart plasma. Following reaction mixture called the control was prepared at 27° C.: Stuart plasma 0.5 ml., 0.4 per cent 'Cephalin' 0.1 ml., 0.05 *M* calcium chloride 0.1 ml. At time-intervals samples of 0.1 ml. were taken for the 2-stage prothrombin determination. A modification of the original two-stage method was used in which the lung extract thromboplastin was replaced by 0.1 per cent cephalin suspension mixed with 500 units of autoprothrombin *C*. Top curve same as control, but with DEAE-cellulose prothrombin added at zero time. Bottom curve same as control, but with non-chromatographed prothrombin added at zero time.

An abnormal prothrombin molecule has been created in our laboratory by changing the one isolated from normal plasma. The known alteration made in the structure is at the *C*-terminal amino-acid location. Here there seems to be a modification that is not noticed on the basis of a complete amino-acid analysis[5]. The chromatography apparently destroys what is built into the prothrombin molecule during its cellular synthesis. Failure to incorporate this specific or related structure could easily account for an abnormal prothrombin molecule in Stuart–Prower 'deficient' plasma. Moreover, this perspective may be applicable for exploration in other abnormalities such as factor VII and IX deficiencies, where prothrombin derivatives are known to be involved[3,4].

This work was supported by a grant *H*-5141 from the National Institutes of Health, U.S. Public Health Service. We thank John B. Graham of the University of North Carolina for a sample of Stuart plasma and also John A. Penner of the University of Michigan for a sample of factor *X* deficient plasma.

Role of the Krebs Cycle in Ethylene Biosynthesis

SEVERAL reports have appeared in the literature recently on ethylene biosynthesis in fruit and in the mould, *Penicillium digitatum*. With apple tissue, Burg and Thimann[1] concluded, from the findings of isotope experiments, that ethylene is derived from sugar via pathways unrelated to glycolysis, the Krebs cycle, the pentose phosphate pathway or the glucuronic acid pathway. Phon-Chon-Ton[2] demonstrated that in *P. digitatum* ethylene can derive its carbon skeleton from glucose or glycerol carbon atoms and suggested that a long sequence of reactions may have been involved in the biosynthesis of ethylene from glucose.

The mechanism for the production of ethylene in the mould, *P. digitatum*, has also been studied in this laboratory. Glucose and amino-acids labelled with carbon-14 have been used as substrates to a stationary culture of the mould growing aerobically in 100 ml. of a medium containing the essential salts, 0.2 per cent yeast extract and 1.25 per cent glucose[3]. After three days of incubation at 24° C, the carbon-14 labelled substrate was introduced into the culture, and a stream of sterile air was allowed to flow through the enclosed incubation flask at a rate of 40 ml. per minute.

The carbon dioxide and ethylene produced by the mould were trapped respectively by an ascarite column and a silica gel column cooled in a dry ice–acetone bath. The trapped ethylene was released from the column at 50° C and swept into the gas chromatography column with a stream of helium gas. Pure ethylene fraction separated on the chromatography column, consisting of molecular sieve (Wilkens Instrument and Research, Inc., P.O. Box 313, Walnut Creek, California) and silica gel, was collected in a fraction collector submerged in a liquid nitrogen bath. The radioactivity of the ethylene was determined upon the addition of 15 ml. of ice-cold scintillation solvent (1,000 ml. of toluene, 6 g of 2,5-diphenyloxazole and 75 mg of 1,4-*bis*-2(5-phenyloxazole benzene) to the liquefied ethylene, and the mixture was counted by means of a 'Tricarb' scintillation spectrometer model 314 *EX*. The amount of ethylene was estimated by integrating the area under the curve plotted on the gas chromatograph recorder. The silica gel column was replaced daily and an analysis of the ethylene trapped thereon provided information on the time course for ethylene production by the mould. On the average, 1–1.2 μmoles of ethylene were produced by the mould culture over a period of 24 h with the peak production rate being 6–7 days after inoculation. This observation is in accordance with that reported by Phon-Chon-Ton[2].

With glucose labelled with carbon-14 as substrate, the specific activities of ethylene were found to be 55, 41, 99 and 45 dpm per μmole of ethylene respectively from 5 μc of [1–^{14}C] glucose, [2–^{14}C] glucose, [6–^{14}C] glucose and [U–^{14}C] glucose. The findings are basically similar to those reported by Burg and Thimann[1] with apple tissue. The low magnitude of the specific activity of ethylene derived from [U–^{14}C] glucose, however, leads one to believe that C-3 and C-4 of glucose did not contribute much to the formation of the ethylene skeleton. If one assumes that the contribution of C-5 of glucose to ethylene biosynthesis is of the same magnitude as that of C-2 of glucose, a simple calculation using the specific activities of ethylene observed in the glucose experiments will show that the specific activity of ethylene derived from either C-3 or C-4 of glucose is of the order of $\frac{(45 \times 6) - (55 + 99 + 41 + 41)}{2} = 17$ dpm per μmole. These results, along with the understanding that in *P. digitatum*[4] glucose is catabolized primarily via the glycolysis-Krebs cycle pathway (77 per cent)[4], suggest that the ethylene skeleton may have derived its origin from degradation products of glucose in the glycolysis-Krebs cycle sequence.

In order to verify the foregoing described contention, a series of experiments have been carried out with amino-acids labelled with carbon-14 as the tracing substrates. The amino-acids used were glycine, alanine, aspartic acid and glutamic acid, each is closely related to a member of the Krebs cycle. The use of amino-acids instead of Krebs cycle acids is motivated by the results of preliminary experiments in which it was demonstrated that amino-acids can be readily utilized by the mould in the presence of glucose.

The amino-acid experiments were carried out in essentially the same manner as that of the glucose experiments. Mould was allowed to grow aerobically in salts–yeast extract–glucose medium for three days, at which time approximately 9 μmoles of the labelled amino-acid, having a specific activity of 0.55 μc per μmole, were introduced into the incubation medium. Production of ethylene was followed by daily chromatographic and radiochemical analysis over a period of six days. The specific activities of ethylene observed in these experiments were those totalled for the 6-day period, and they were normalized to equal substrate radioactivity, that is, 5 μc per 9 μmoles of each of the amino-acids.

The specific activities of ethylene derived from the labelled alanine samples are 114, 182 and 799 dpm per μmole of ethylene from C-1, C-2 and C-3 of alanine respectively. This fact is in line with the findings in the glucose experiments, if one visualizes glucose as being converted to 2 moles of pyruvate via the glycolytic pathway with C-1 or C-6 of glucose being equivalent to the methyl carbon atom of the pyruvate. The fact that C-1 of alanine was not incorporated to ethylene to any great extent suggests that the pyruvate may have undergone oxidative decarboxylation, giving rise to acetyl CoA prior to its conversion to ethylene.

The mechanism involved in the conversion of acetyl CoA to ethylene is a complex one since, on one hand, acetyl CoA can be converted to glyoxylate prior to the formation of ethylene or, on the other hand, it can be routed into the Krebs cycle, giving rise to a number of Krebs cycle intermediates which are in turn converted to ethylene molecules. That the glyoxylate is probably not involved directly in the biosynthesis of ethylene is indicated by the finding that the relative specific activities of ethylene derived from C-1 and C-2 of glycine were 13 and 115 dpm per μmole respectively. Although C-2 of glycine was preferentially utilized for ethylene biosynthesis, the extent is much less in comparison with the case of C-3 of alanine.

It therefore appears that acetyl CoA, as derived from glucose via the glycolytic pathway, may have been further catabolized by way of the Krebs cycle, giving rise to a compound which serves as a more direct precursor of ethylene. The nature of this compound is revealed by the findings in the labelled aspartate and glutamate experiments. Specific activities of ethylene derived from aspartate were found to be 304 and 25 dpm per μmole from C-3 and C-4 aspartate respectively. This fact is in line with the findings observed in the alanine experiments, inasmuch as C-3 of aspartate is metabolically corresponding to the C-3 of alanine.

More striking results are observed in labelled glutamate experiments. The specific activities of ethylene derived from C-1, C-2, C-3(4) and C-5 of glutamate were 5, 30, 624 and 8 dpm per μmole of ethylene respectively. These results suggest that C-3 and C-4 of glutamate are closely related to the precursor of ethylene in the mould.

On the basis of these findings, it can be speculated that the conversion of glucose carbon atoms to ethylene followed the route involving the glycolysis and the conversion of acetate to α-ketoglutarate via the Krebs cycle steps. The α-ketoglutarate so formed is presumably converted to succinic acid by oxidative decarboxylation and oxidation of the succinate, giving rise to fumarate. It is possible that the carbon skeleton of ethylene or its precursor is derived directly from the middle carbon atoms of fumarate. It is recalled that earlier Buhler, Hansen and Wang[5] observed that ethylene labelled with carbon-14 can be incorporated into the acid fraction of avocado fruit. The radioactivity was found to be located primarily in the fumaric acid and succinic acid, in particular the carboxyl carbon atoms Although it is not possible to directly correlate the present work and the previous findings with fruit, the intimate relationship between ethylene and the Krebs cycle acids is, nevertheless, indicated by the results in both experiments

Occurrence of *Bis*(β-Amino-β-Carboxyethyl) Trisulphide in the Hydrolysates of Wool and other Proteins

Investigations of acid hydrolysates of wool labelled with sulphur-35, and of non-radioactive wool hydrolysed with ^{35}S-cystine, have shown the presence of unidentified sulphur compounds derived from cystine[1,2] The most abundant of these (I) increased in amount with increasing time of hydrolysis up to 100 hr, when about one-tenth of the original sulphur in wool was present as (I) Somewhat smaller amounts of (I), representing about one-fiftieth of the protein sulphur, were found in acid hydrolysates of insulin, ribonuclease and bovine serum albumin, but none could be detected in hydrolysates of lysozyme and β-lactoglobulin

We have recently obtained 1 4 gm of (I) as a stable, white, microcrystalline powder from 150 gm of wool by the following procedure The wool was hydrolysed in 1 5 litres of 5 7 *N* hydrochloric acid for 100 hr under reflux, and the hydrolysate fractionated by chromatography on a 9-cm × 40-cm column of 'Zeo-Karb 225' (× 4) resin in the H$^+$ form by elution with 2 5 *N* hydrochloric acid[3] (I) was eluted with phenylalanine and tyrosine, and was separated from these by subsequent chromatography on a 4-cm × 15-cm column of starch by elution with 2 1 (v/v) *n*-propanol/0 5 *N* hydrochloric acid[4] Traces of contaminating carbohydrate were removed by re-chromatography of (I) on a 2 5-cm × 5-cm column of 'Zeo-Karb 225' (× 4) in the H$^+$ form eluted with 2 5 *N* hydrochloric acid (I) was isolated from the aqueous solution of its hydrochloride by the addition of pyridine until the *p*H was 4 6

The properties of (I) have led us to conclude that it is the previously unknown trisulphide analogue of cystine, *bis*(β-amino-β-carboxyethyl) trisulphide, $[HOOC\ CH(NH_2)\ CH_2]_2S_3$

Thus, when (I) is oxidized by bromine, with the theoretical uptake of oxygen, cysteic and sulphuric acids are obtained in the molecular proportions of 2 1 On treatment with cyanide under the conditions of Sorbo[5] (omitting Cu^{++} ion), one-third of the sulphur of (I) is converted to thiocyanate Approximately one-third of the sulphur of (I) is released as hydrogen sulphide during reduction with tin or zinc, and hydrochloric acid, and the reduced solution contains cysteine and no other thiol By 'formol' titration (I) has an equivalent weight of 138 (theoretical 136) Elementary analysis gave C, 27 1, H, 4 4, N, 10 0; S, 36 4 per cent ($C_6H_{12}O_4S_3N_2$ requires C, 26 5, H, 4 4, N, 10 3, S, 35 3 per cent)

The compound is stable in the dry state or in strongly acid solutions, but in neutral or alkaline solutions dismutates to give cystine and other products When chromatographed on paper in *n*-butanol/acetic acid/water (4 1 5 v/v), (I) moves as a single spot with R_F 0 09, but analytical amounts (< 0 5 mgm) chromatographed on 0 9-cm × 40-cm columns of 'Zeo-Karb 225' (× 4) resin by the hydrochloric acid elution method are resolved into a double peak, indicating the presence of two stereoisomers

By refluxing a suspension of *N*-acetylcysteine in chloroform containing sulphur dichloride with constant stirring for 40 hr, distilling off the chloroform, and hydrolysing the residue for 4 hr in 5 *N* hydrochloric acid we have obtained, in addition to cysteine, cystine and one other unidentified minor product, a substance the chromatographic behaviour of which is identical with that of (I), but which has not yet been further characterized

The formation of the trisulphide must involve the scission of a carbon–sulphur bond in cystine We have, therefore, examined cystine solutions that had been subjected to a 4 × 10^7 r dose of γ-irradiation from a multicurie cobalt-60 source Traces of (I), about 3 per cent of the initial cystine sulphur, were found, but not sufficient to make this a practicable source of the compound

This work, which is sponsored by the Agricultural Research Service of the U S Department of Agriculture under the authority of Public Law 480, will be published in detail elsewhere

An Interpretation of the Transition in Composition of Soluble Lipoproteins

A recent examination[1] of a wide range of soluble lipoproteins has shown that a transition in the proportions of protein, phospholipid and neutral lipid occurs in the region where these three components are present in about equal amounts This transition is clearly evident when the percentage of neutral lipid (Y) is plotted against the proportion of phospholipid in the protein–phospholipid complex (X) Curves fitted to the experimental points for 42 lipoproteins by least squares showed that two linear equations

$$Y = 8\ 54 + 51\ 6\ X \text{ (for } Y < 40 \text{ per cent)} \qquad (1)$$

$$Y = 8\ 73 + 99\ 5\ X \text{ (for } Y > 40 \text{ per cent)} \qquad (2)$$

represented the data more adequately than a cubic equation fitted to all the points However, both types of equation show evidence of the transition since the discontinuity between the linear equations and the point of inflexion in the cubic occur in the same region From other experimental evidence[1,2] it was suggested that lipoproteins represented by equation (1) may have a structural integrity approaching that of a protein molecule, while those conforming to equation (2) evidently have a lipid core A difference in structure, however, does not indicate why this transition occurs where the components are present in equal proportions The balance of non-polar forces between the water-soluble protein–phospholipid complex and neutral lipid was examined and appears to provide a possible explanation for the transition

It was assumed that polar forces are primarily responsible for the interaction between protein and phospholipid, that non-polar forces predominate between neutral lipid and this complex, and that the CH_2 content of each component can be used as an index of the non-polar forces involved, although the availability and interaction potential of each CH_2 group are unknown There is experimental evidence to support some of these assumptions, for example, most of the neutral lipids can be extracted from lipoprotein solutions with ethyl ether, but more-polar lipid solvents are required to extract all the phospholipid

The CH_2 content of the protein moieties of a few lipoproteins was estimated from their amino-acid composition[3] and Waugh's[4] estimates of the CH_2 values for amino-acids, and found to be 17 m moles/gm The CH_2 content of phospholipids and neutral lipids was estimated from their average composition[5,6] and molecular weight Phospholipids had a CH_2 content of 42 ± 2 m moles/gm and neutral lipid ranged from 57 m moles/gm for the predominantly triglyceride types to 63 m moles/gm for the cholesterol-rich low-density fractions of blood serum The lower value was considered more representative of neutral lipids in most lipoproteins These values (17, 42 and 57 m moles/gm) were used to compute the CH_2 content of the lipoproteins represented by equations (1) and (2) since their CH_2 content is determined primarily by the proportions, rather than the composition, of the three components

These figures show that the sum of the CH_2 contents of the protein and phospholipid is essentially equal to that in the neutral lipid when the three components are present in equal proportions, as they are at the transition zone To extend this comparison over the entire range of lipoprotein composition, the CH_2 content of the neutral lipid was subtracted from the CH_2 content of the predominantly polar protein–phospholipid complex, and this algebraic difference is plotted against the total CH_2 content of the lipoproteins in Fig 1, together with a supplementary scale that serves to indicate their total lipid content The solid lines represent the values obtained from the fitted curves described by equations (1) and (2) For comparison, the points represent the average compositions reported[5] for the four main classes of serum lipoproteins, and are independent of the above equations

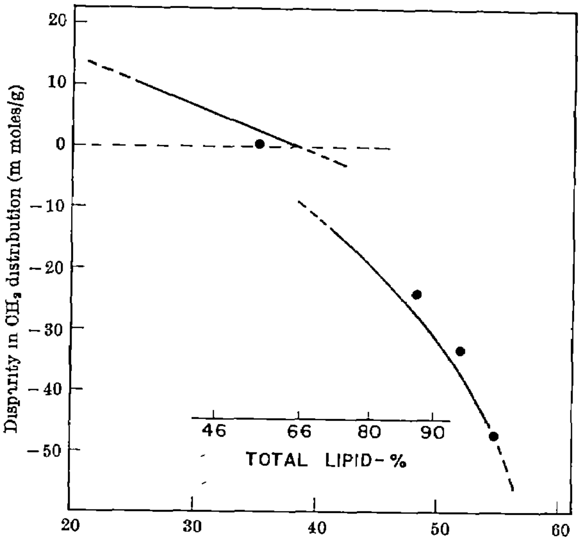

Fig 1 Disparity in CH_2 distribution in lipoproteins of different CH_2 contents Disparity is CH_2 content of protein and phospholipid less that in neutral lipid Total lipid content is indicated on inserted abscissal scale

The slope of the lines and the discontinuity at the transition zone, as shown in Fig 1, are naturally dependent on the equations used for their construction The position of the curves, however. is determined by the CH_2 content of the three components Lipoproteins with positive ordinates have sufficient CH_2 groups in their protein–phospholipid complex to interact with all those in the neutral lipid and the latter could therefore be distributed throughout the volume of the molecule Beyond the discontinuity the CH_2 groups on the neutral lipid predominate (negative ordinates) and, if they interact strongly with one another, as suggested by the abrupt transition, this would produce a lipoprotein with a lipid core A similar conclusion has been reached on the bases of particle size and neutral lipid content[1] Although the agreement with observation may be fortuitous, the present interpretation, based on the relative number of CH_2 groups in the neutral lipid and other components, is consistent with available information on lipoproteins and possibly explains why the transition zone appears where the three components are present in equal amounts

Non-Enzymatic Hydroxylation of Aromatic Compounds

In a recent communication, Dewhurst and Calcutt[1] discussed the hydroxylation of polycyclic aromatic hydrocarbons by the Udenfriend[2] system This system, consisting of a buffer, substrate, ascorbic acid and a metal complex in the presence of oxygen, is capable of hydroxylating aromatic compounds[2,3] However, the system is also capable of oxidizing aliphatic[4,5] and heterocyclic[6–8] compounds, and hence the hydroxylation of aromatic compounds may be regarded as a special aspect of a more general oxidation reaction

The hydroxylation reaction is believed to proceed through two intermediate steps (1) the metal-catalysed oxidation of ascorbic acid to hydrogen and monodehydroascorbic acid free radicals[9], (2) interaction of these free radicals with the substrate[10]

Under the experimental conditions usually adopted in the Udenfriend hydroxylation, the rate-determining step of the reaction is the first This will, in turn, depend on the catalysing power of the metal complex present in the system The availability of the metal ion will then be a function of the stability of the metal complex and the redox potential of the cation It is unlikely, however, that a simple correlation between the extent of hydroxylation and the stability constant of the metal complex can be determined experimentally Under the oxidizing conditions of the reaction the true value of the stability constant of the complex is unknown and may be different from the constant under normal conditions Hence a relationship between the yield of hydroxylated product and the stability constant of the complex will be of only a semi-quantitative nature

We have studied the effect of various conditions on the Udenfriend hydroxylation of aniline with a system consisting of 710 μmoles ascorbic acid, 75 μmoles cation, 400 μmoles disodium salt of ethylenediamine tetraacetic acid, oxygen and 300 μmoles substrate in a phosphate-buffered aqueous solution of a total volume of 15 ml The cation used was ferrous ion, containing ferric ion In view of the kinetics of the reaction, and of our unpublished results and results of the studies of the ascorbic acid-induced oxidations of non-aromatic compounds, we are of the opinion that the ferric state is the significant state for the catalysed oxidation of ascorbic acid and subsequent oxidation of the substrate In general, the higher valence state of the cation is necessary for the catalysis of the reaction

Various ligands were added to the model system, and the effect of the metal complexes on the activity of the system in converting aniline to *p*-aminophenol is shown here (Fig 1) The *p*-aminophenol was determined by Brodie's method[11], while the existence of *o*-aminophenol was established by paper chromatography The results indicate the absence of a simple correlation between the yield of product and the stability constant of the complex

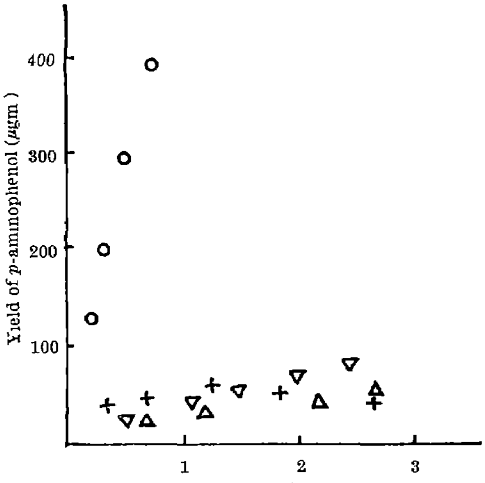

Fig 1 Effect of complexing agents on the conversion of aniline to *p*-aminophenol O Ethylenediamine tetraacetic acid, Δ, tartaric acid, +, acetyl acetone, ∇, oxalic acid

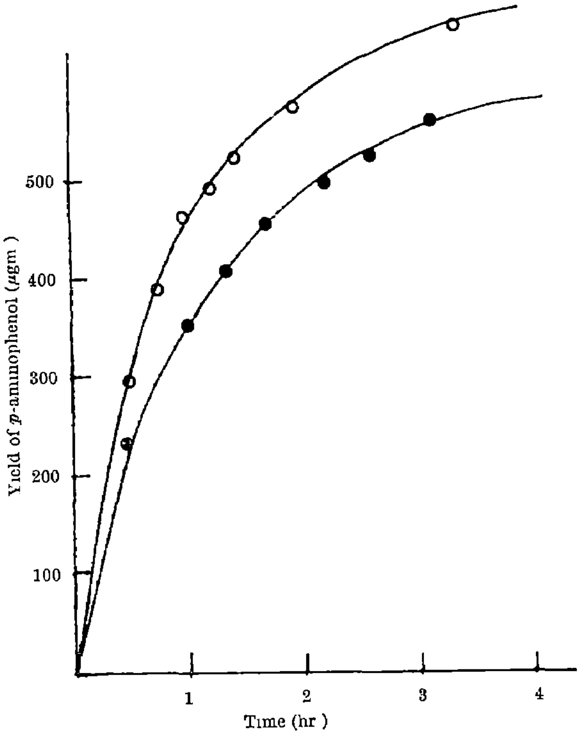

Fig 2 Inhibition by fluoride ion of the conversion of aniline to *p*-aminophenol O, Ethylenediamine tetraacetic acid, ●, ethylenediamine tetraacetic acid plus fluoride

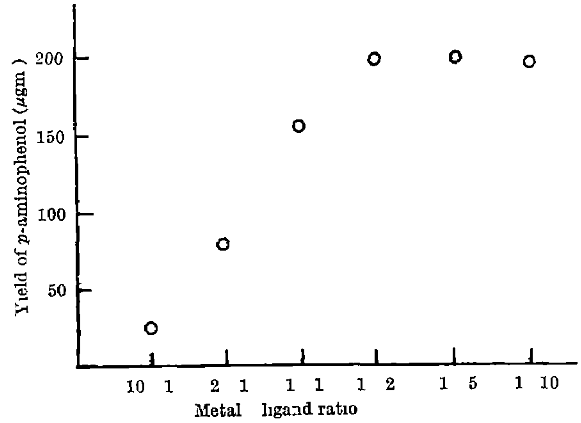

Fig 3 Effect of varying metal ligand ratio on the conversion of aniline to *p*-aminophenol

Dewhurst and Calcutt[1] reported the failure of cyanide to inhibit the system completely This is in agreement with our results for fluoride inhibition shown here (Fig 2) For the iron ethylenediamine tetraacetic acid complex, the yield of product is an exponential function of time, an apparent first order reaction If fluoride is then added to the system the activity of the system is only partially inhibited, and is still of the same form, that is, the yield of product is again exponential with time At this stage no explanation is offered as to this apparent anomalous behaviour

Not only the nature of the metal complex but also the metal ligand ratio is of importance in a consideration of the hydroxylating power of the system Butt[12] found that the metal ligand ratio had marked effects on the autoxidation of ascorbic acid If the assumption is correct that the rate-determining step in the hydroxylation process is the metal-catalysed autoxidation of ascorbic acid, then the metal ligand ratio should have a marked effect on the overall yield of hydroxylated product We have shown this to be correct (Fig 3)

PHYSIOLOGY

Excretion of Haptoglobin in Normal Urine

The presence of haptoglobin in normal urine was first suggested by Patte *et al* [1] and was later established by direct immuno-precipitation[2] The haptoglobin found in urine gave a reaction of immunological identity with purified plasma haptoglobin However, it could not be detected in 4 of 12 individuals whose urine was examined

The varying ability of different normal individuals to excrete haptoglobin could be ascribed to the particular genetically controlled haptoglobin type of the individual Thus the low molecular weight of haptoglobin of type 1-1 should be more easily excreted by the kidney than the high molecular weight polymers characteristic of haptoglobin type 2-2 In order to test this hypothesis urine was collected from one individual of haptoglobin type 1-1, six individuals of type 2-1 and two of type 2-2 Twenty-four-hour urine specimens were used The urine proteins were concentrated by means of ultra-filtration as described by one of us[2] Visking dialysis tubing of 8/32 in inflated diameter was used as the ultra-filtration membrane The urines were concentrated about 2,000–3,000 times to volumes of 0 30–0 68 ml Before the final concentration step the urine was dialysed against 0 9 per cent saline

The urine concentrates and sera from the same persons were examined by vertical starch gel electrophoresis in borate buffer at *p*H 8 6 (ref 3) Hæmoglobin was added to the samples prior to electrophoresis After the electrophoresis the gel was cut into two slices The top slice was stained for protein with amido black and the bottom slice for haptoglobin with the benzidine reagent The protein staining showed the presence of distinct albumin and transferrin *C* bands Two or three additional protein bands were observed between the albumin and transferrin bands The benzidine stain showed the presence of haptoglobin in all urines except in the two individuals of haptoglobin type 2-2

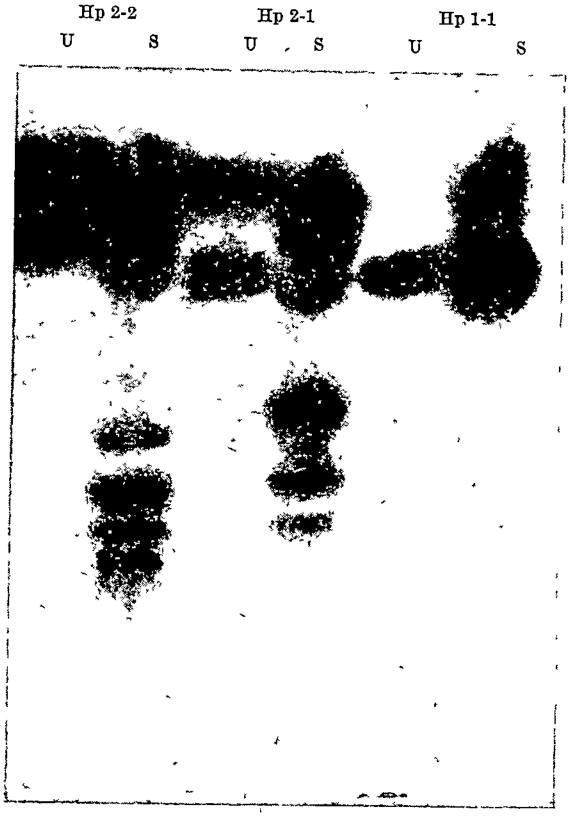

Fig 1 Analysis by starch gel electrophoresis of haptoglobin in sera (S) and urines (U) of normal individuals of the haptoglobin types 2-2, 2-1 and 1-1 Benzidine stain Hæmoglobin was added in excess prior to electrophoresis and bands of free hæmoglobin are also seen

Fig 1 shows a comparison of the patterns of the three haptoglobin types in serum and urine The urine of the individual of haptoglobin type 1-1 had a distinct haptoglobin 1-1 band and this band was also observed in the urines of the six individuals of haptoglobin type 2-1 In addition, the urine from type 2-1 individuals contained small amounts of haptoglobin polymers, as evidenced by one or two weak bands corresponding to the most rapidly moving polymeric bands of the corresponding serum The relative intensities of the haptoglobin 1-1 band and the polymeric bands varied in different urines The urinary 2-1 pattern reproduced in Fig 1 was one with a relatively strong 1-1 band and only one weak polymeric band If the tubular re-absorption of protein is non-selective[4] the observed variation might reflect individual variations in the selectivity of the glomerular filter Generally, the urinary haptoglobin bands showed a somewhat higher mobility than the corresponding serum bands

From this investigation it appears that haptoglobin polymers occur in detectable quantities in the urine from individuals of type 2-1 but not in urine from individuals of type 2-2 Indeed, polymeric haptoglobin would be more easily excreted in urine of type 2-1 individuals than in urine of type 2-2 individuals since part of the polymeric haptoglobin from 2-1 individuals has a smaller molecular size than the polymeric haptoglobin from 2-2 individuals[5] The fact that not even the most rapidly migrating polymer of the 2-2 sera could be detected in the corresponding urine is probably due to the low concentration in serum of this polymer (Fig 1)

It has been shown previously that patients with the nephrotic syndrome belonging to haptoglobin type 1-1 may excrete several grams of haptoglobin per litre of urine[6] Using starch gel electrophoresis, Marnay[7] recently studied the haptoglobin patterns in nephrotic urines of patients belonging to the types 2-2 and 2-1 Haptoglobin was not observed in the urines of patients of type 2-2, whereas the 2-1 urine showed distinct 1-1 bands and two weaker bands corresponding to the most rapidly migrating polymeric bands in serum. The present investigation shows that the haptoglobin patterns of normal urine are similar to those reported for nephrotic urine Rowe and Soothill[8] have presented evidence interpreted as indicating a lower degree of selectivity from the point of view of molecular weight for the excretion of serum proteins by the normal than by many nephrotic kidneys Using a quantitative immunochemical gel diffusion technique, these authors reported approximately the same urine/serum ratios for albumin, transferrin, γ-globulin and ceruloplasmin for normal individuals whereas a high selectivity between these proteins has been reported in nephrotic patients showing minimal renal histological changes[9] The present investigation, in conjunction with the study of Marnay, indicates that the renal discrimination for haptoglobins of differing molecular size is markedly selective and similar for normal and nephrotic kidneys

Pigment and the Olfactory Mechanism

THE pale-yellow to dark-brown colour of the olfactory epithelium has led many to suppose that pigment is essential to olfaction[1–3], and the finding that there are stores of carotenoids in the olfactory epithelium of cattle[4,5] has given some support to the view that these compounds are involved[6,7] More specifically, Briggs and Duncan[5] have recently proposed that—on analogy with vision—carotenoids are the receptors of energy from odorous molecules The purpose of this note is to present evidence inconsistent with such theories

If carotenoids were as essential to olfaction as they are to vision they should commonly be found in vertebrate olfactory epithelia There seems to be no evidence for this, indeed, Gerebtzoff *et al* [2] found no carotenoids in rabbit or sheep olfactory tissue Are there, then, species differences in the distribution of these pigments ? To test this hypothesis, olfactory epithelia from one cow, 32 albino rats, 29 black rats and three pigs were investigated[8] The heads of the freshly killed animals were sawn in half along the nasal septum to expose the turbinals, and all yellowish or yellowish-brown epithelium was dissected out and weighed After grinding down the tissues to a smooth paste, they were saponified in 80 per cent methanolic potassium hydroxide solution, and then extracted repeatedly with petroleum ether The pooled extracts for each group and a control solution of β-carotene were chromatographed separately on alumina impregnated filter paper[9] in an atmosphere of carbon dioxide The deep yellow bands of pigment separating out from the cow extract, and the single band on the control strip, gave strong positive reactions with antimony trichloride (tha Carr–Price reagent), indicating considerable concentrations of β-carotene and other carotenoids in the cow tissue The same test, however, failed to reveal any carotenoids in the almost colourless extracts from the rat and pig groups

Non-carotenoid pigments present in the saponifiable portions from all groups, and separable into three fractions by paper chromatography, are apparently responsible for the yellowish-brown colour of the rat and pig olfactory epithelia They appear to be either auto-oxidation products of phospholipids[10], or are adsorbed on to phospholipids (predominantly lecithins)[2] In view of widely cited reports that albinos are anosmic (due—it is implied—to the lack of olfactory pigment)[1], it is interesting that no significant differences could be found in the colour, quantity or composition of these pigments in the black and albino rats It seems likely that such claims have arisen through a misinterpretation of the phenomenon of photodynamic sensitization

The results indicate that while there are stores of carotenoids in the olfactory epithelia of cattle, these pigments are absent, or present in only trace quantities. in the epithelia of rats and pigs It appears, then. that cattle are the only species in which carotenoids have been identified in olfactory tissue It is significant that they are also among the few mammalian species known to store primary carotenes in the fatty tissues of their bodies, and among those species which do not are the rat, pig and cat Thus Goodwin's suggestion that the carotenoids in cattle olfactory tissue are waste products without functional significance seems a reasonable one[11]

The appearance of anosmia in rats deprived of vitamin A[6,12], and the return of olfaction in some anosmic patients, have been cited—but cannot be accepted—as further evidence that carotenoids are involved in the olfactory process[5] Responses to odour depend on nasal mucous membrane function[13] and such membranes are highly sensitive to variations in vitamin A concentrations of the body[12,14] Furthermore, the extent to which recovery of 'olfaction' reflects changes in odorant access to the acutely chemo-sensitive 'free' nerve endings of the nasal mucosa is not known

Finally, it should be emphasized that radiation theories of olfaction—which include those which allot a role to carotenoids and other pigment in the olfactory mechanism—have received extensive and important criticisms from Thompson[15] on both theoretical and practical grounds, and appear to be untenable In any event, there exist theories which disregard colour, and which seem more in accord with available evidence[16] The assumption that the pigment is present in the receptors is without support from the great majority of relevant studies[17], while there are reports that the pigment and olfactory areas do not coincide[18], and that it is lacking from the olfactory area of some species with known olfactory powers[2] Thus, until there is much more information concerning the location, chemical composition, and distribution of the pigment complex in representative vertebrate species, any theory implicating these compounds in the olfactory process must be viewed with extreme caution

IN his critical review of recent investigations[1,2] on the possible relationship of carotenoid pigments to olfaction, Dr D G Moulton has made four points that he regards as conclusive against carotenoid pigments being involved in the olfactory mechanism We wish to comment on the validity of these four points

(1) It is claimed that carotenoids do not occur in the olfactory epithelium of all mammals Our work[1,3] has so far been confined to the cow and the dog, both of which possess large amounts of olfactory carotenoids Negative findings for rabbits and sheep have been reported by Gerebtzoff and Phillippot[4,5], for salmon by Wright[6], and now for rats and pigs by Moulton

It is well known[7] that some mammals preferentially accumulate carotenoids If carotenoids are present in the olfactory areas of only this group, as Moulton suggests, then why have no carotenoids been detected in the olfactory areas of sheep (a carotenoid-accumulator[8]) while they have been detected in the olfactory area of the dog (which is not a carotenoid-accumulator[9,10]) ? This evidence renders untenable Moulton's hypothesis for the distribution of olfactory carotenoids

An alternative hypothesis concerns the difficulties of carotenoid analysis and wide differences in tissue concentrations Thus, in the experimental work described in Moulton's communication, detection of carotenoids was by reaction with the Carr-Price reagent on paper chromatograms This is scarcely sufficient to identify carotenoids, for not all react with antimonytrichloride, which in any event is not specific for carotenoids, while some give very transitory colours[11] As spectrophotometric methods can be applied to detect even very small amounts of carotenoids, it is essential that this method be used wherever possible, together with a comparison of chromatographic behaviour, *cis-trans* equilibration, and derivative formation against known standards where quantities available render these tests possible As an example of the difficulties involved in the detection of carotenoids, consider the case of retinene in insects Many investigators[12] have failed to detect this haplocarotenoid in insect eyes, but a re-examination[13] of this question has shown that retinene occurs in most insects, and the insect visual pigments so far obtained[14] are retinene-containing rhodopsins It is quite possible that a similar situation exists with olfactory carotenoids, which apparently show very wide species variations in concentrations and the olfactory tissues are difficult to collect and preserve

(2) Moulton claims that the loss of olfaction by animals raised on a carotenoid-free diet is not evidence that carotenoids are involved in olfaction as the loss is open to other explanations This is undoubtedly true But even if the carotenoid hypothesis of olfaction were based solely on this prediction (which it clearly is not), it cannot be falsified in this manner The nutritional observations are merely supplementary evidence It still remains to be demonstrated whether or not carotenoid-deficient animals are anosmic due to lack of essential olfactory pigment or to the sort of changes mentioned by Moulton

The pathological changes in epithelia occurring in carotenoid-deficient animals are thought to be due to an absence of carotenoids from the epithelial cells Hence changes in the olfactory epithelia in carotenoid deficiency indicates that carotenoids are normal, essential constituents of the healthy tissues

(3) Vitamin A has proved of clinical benefit in the treatment of anosmia The effect is definite and marked in all but a few patients Moreover, the recovery of olfaction is almost always accompanied by the same clinical signs namely, the recovery first of the ability to detect unpleasant odours, followed some appreciable time later by the return of pleasant odours The suggestion of Moulton's that the effects are merely due to an improvement in the status of tissue vitamin A is most unlikely The patients showed no signs of avitaminosis A and there was no clinical evidence of dryness of the nose[3]

(4) Moulton's criticisms of our postulated molecular basis of olfactions do not seem valid There is no doubt that some naturally occurring carotenoids occur in the *cis*-form[15] and there is no evidence either way on the geometrical isomerization of the olfactory carotenoid Some preliminary evidence on extracts from the cow suggests that an appreciable proportion is present as hindered forms[16] The evidence on the presence or absence of pigment in the receptor hairs is inconclusive There is no doubt that most of the pigment is present in the supporting cells and in Bowman's glands, but whether physiologically significant amounts of pigment are present in the receptors is unknown Certainly one group of workers[17] who have studied the histology of the olfactory sensory cells and pigment distribution were struck by the resemblance to the retina Perhaps the carotenoids in the Bowman's gland secretion, which bathes the receptor hairs, are the primary odour receptors

In summary, we would say that, first, the evidence regarding the occurrence of carotenoids in the olfactory area of mammals is insufficient to draw any definite conclusions, and that the difficulties of carotenoid detection, illustrated by the case of insect retinene, should be borne in mind in assessing the evidence Secondly, that our clinical findings on anosmia cannot be ascribed to dietary lack of vitamin A Thirdly, that the histology of the olfactory areas is insufficiently understood to rule out a role for carotenoid-proteins in odour reception

Effect of Environmental Temperature on Conditioning in the New-born Poikilothermic Rat

In the rat a period of poikilothermy exists for approximately the first seventeen days of life[1-2] In this phase of the development action potentials and nerve conduction rate decrease with the lowering of the environmental temperature[3] Temperature may change, therefore, the ability of the new-born rat to learn the conditioned leg withdrawal to a vibrotactile stimulus

Fifty-six new-born Sprague-Dawley rats were used The animals were immobilized and the unconditioned stimulus, a direct current electric shock of 1 0 m amp and 50 msec duration, was delivered to the foot of the right foreleg, which was connected to a motion displacement recorder[4] The conditioned stimulus was a vibration of 128 c/s applied to the rat's chest and preceded presentation of the unconditioned stimulus Trials with the vibration were given all animals to ensure that leg withdrawal did not occur prior to conditioning Forty rats were divided into four equal groups Each group received eighty trials of the conditioned and unconditioned stimulus The four groups differed in the following manner in groups I and II the environmental temperature during conditioning was 28° C whereas in groups III and IV it was 23° C Furthermore, in groups I and III the conditioned stimulus preceded the onset of the unconditioned stimulus by 1,800 msec and for groups II and IV the interval was 900 msec (Fig 1) The two conditioned stimulus values utilized in this investigation were based on previous work demonstrating reliable conditioning in the new-born rat for durations between 600 and 2,400 msec[4] Testing was done in a temperature-controlled room (± 1 0° C) and the body temperature of the subject was monitored by a rectal thermocouple (± 0 1° C) Conditioning commenced when the rectal temperature had stabilized at either 28° C or 23° C For each of the experimental groups a pseudo-conditioning control group ($N = 4$ per group) was tested utilizing the same conditioned and unconditioned stimuli, but with their order of presentation random A conditioned response was defined as any right foreleg withdrawal occurring in the interval from 50 msec after the onset of the conditioned stimulus to its termination

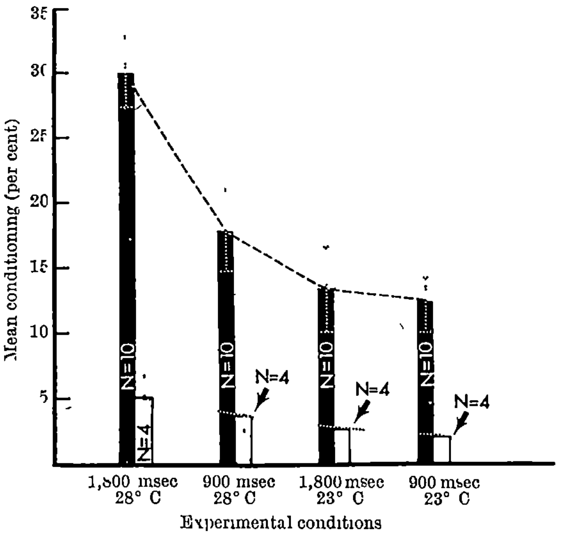

Fig 1 Environmental temperature affects the level of conditioning in poikilothermic new-born rats This variable interacts with the duration of the conditioned stimulus Black bars represent experimental groups, white bars the respective pseudo-conditioning control groups The range of one standard deviation is indicated at the top of each group bar

Fig 1 presents the mean per cent conditioning and standard deviation for the four experimental and control groups based on the eighty conditioning trials

The performance difference between experimental and control groups indicates the validity of the conditioning data Rats in the 1,800 msec, 28° C group manifested the highest performance level (mean per cent = 29 8, *S D* = 5 66) followed by the 900 msec, 28° C group (mean per cent = 17 9, *S D* = 6 63) In turn, both these groups were superior in conditioning to the 1,800 and 900 msec, 23° C treatments (mean per cent = 13 2, *S D* = 6 39, mean per cent = 12 2, *S D* = 3 50, respectively) Although the 1,800 msec, 23° C group was superior to the 900 msec, 23° C condition, this difference amounted to only 1 0 mean per cent

These results clearly indicate an interaction between conditioned stimulus duration and environmental temperature Furthermore, the contention that formation of a conditioned reflex in the poikilothermic new-born rat is significantly altered by environmental temperature is demonstrated by the higher level of conditioning found for the 28° C temperature, as compared with 23° C for both temporal intervals

PATHOLOGY

Pathological Zinc-rich Synapses

Experimental carbon-monoxide hypoxia in the guinea pig, if sufficient in tempo or duration to produce seizure, tends to create nerve-cell soma changes of the 'eosinophilic ischæmic' type relatively selectively in 'region *CA*2' of the hippocampal pyramids '*CA*2' may be defined as the zone of *CA*3-type large neurones the apical-dendrite shafts of which are traversed by the end-bulb of the mossy fibre system[1], and is particularly well delineated in the guinea pig because the 'mischzone' that occurs between *CA*1- and *CA*3-type pyramids in most other mammals is here negligible and the end-bulb is unusually bulbous

In a series of 14 guinea pigs where serial sections of the brain were impregnated by the silver sulphide method for zinc-enzymes[2], after various numbers of exposures of the animals to carbon monoxide, 4 seizure cases in which the '*CA*2 ischæmia' was well marked displayed conspicuous pathology within the end-bulb The 'presynaptic bags'[3] or 'swellings'[4] at the sites of synapses-de-passage of the mossy fibres had here a flattened 'collapsed' appearance, compared with their normal roughly circular contour elsewhere They formed a contiguous series of Morse-code-like 'dashes' outlining the shafts of *CA*2 apical dendrites, giving a railway-track appearance to longitudinally cut shafts In another 6 of the cases (2 without seizures), no ischæmic changes could be detected in *CA*2 somata or processes by Nissl, hæmatoxylin and eosin, PTAH, periodic-acid–Schiff, methylene-blue, luxol-fast-blue or Weil staining, but moderate to severe stages of 'synapse collapse' were present around and along especially soma-proximal parts of shafts within the end-bulb In the remaining 4 (seizure) cases 'collapse' was obscured by 'shrinkage' 7 'controls' with no hypoxia, or with under 30 min survival, and no *CA*2 ischæmia, showed no 'collapse' within the end-bulb in either hemisphere

To test the possibility that such 'synaptic collapse' might be a precursor of ischæmic soma changes wherever hippocampal pyramids synapse with the axons of the granule cells of the fascia dentata, another 7 guinea pigs had ischæmic somata created in 'region *CA*3' by means of other types of hypoxia, such as low oxygen-tension, prolonged ether anæsthesia and circulatory stagnation In none of their 14 hemispheres could a convincing picture be obtained, in varied planes of section, of 'collapse' along the apical-dendrite shaft of even one *CA*3 pyramid Yet in each of the five of these cases in which *CA*2 had no ischæmic somata, the self-same type of 'proximal collapse' was to be seen within the end-bulb as seen in the six non-ischæmic carbon monoxide cases already mentioned (After repeated hypoxic seizures of whatever type, there was a less obvious tendency for 'region *CA*4' to exhibit a sprinkling of ischæmic somata and of 'collapsed' synapses around the soma-membrane of other-than-ischæmic 'pyramids') Presynaptic-bag 'flattened collapse' would therefore appear to be a pathological process essentially confined to the end-bulb and not necessarily spatially related to, though temporally prodromal to, ischæmic soma changes due to hypoxia It may be noteworthy that of the cases showing 'early collapse' but no *CA* ischæmia, one had survived onset of ether anæsthesia by only $3\frac{1}{2}$ h, one had survived the start of low-oxygen-tension exposure by only $1\frac{1}{2}$ h, and one had survived, from the start of exposure to carbon monoxide without seizure, for only 48 min This aspect of the prodromal nature of the synaptic pathology was not under explicit exploration in these experiments

Finally, in 8 guinea pigs experimental seizures were produced by insulin hypoglycæmia Repetitive seizures in 3 created acute non-eosinophilic, but strikingly 'luxolophilic', shrunken-soma cell-changes throughout 'region *CA*1', with no conspicuous changes in other *CA* pyramids In all three of these, synaptic pathology was clearly revealed by the silver sulphide method for zinc Here again it was only within the end-bulb, but it was now characterized by a fairly uniform 'shrinkage' of most of the, still roughly circular, presynaptic bags 3 cases with no detectable *CA*1, or other *CA*, cell-soma changes showed lesser and presumably 'earlier' degrees of 'shrinkage', which tended to be most advanced near the centre of the end-bulb The 2 remaining cases were intermediate in respect of both *CA*1 cell-changes and end-bulb synaptic 'shrinkage' In 4 cases where insulin hypoglycæmia had been combined with carbon monoxide hypoxia, 'shrinkage' seemed to have largely precluded 'collapse'

At the end of my communication dealing with impregnation and histochemistry of the normal zinc-rich synapses[2], I touched on the appearance of a 'diffusion' of heavy-metal substance between the end-bulb and stratum oriens, through *CA*2 After one or two carbon monoxide seizures (5 animals) the intensity of this 'diffusion' was diminished below normal After three or more seizures (7 animals) it had completely disappeared in both hemispheres Within the 12 brains the degrees of 'diminished diffusion' roughly paralleled the degrees of 'synaptic collapse' in related end-bulbs This might be an indication that zinc normally 'overflows' from the mossy fibre system into stratum oriens in the region of *CA*2 (Special features at the 'uncal tail' of *CA*2 and the end-bulb will be described elsewhere) In the brains of two animals under the additional influence of amphetamine during carbon monoxide seizures, the degree of 'synaptic collapse' was, however, patently less than a hypothesis of simple causal relationship to 'diffusion' would predict

As remarked elsewhere[5,6], these pathological observations add to the list of peculiarities of the end-bulb *vis-à-vis* the rest of the mossy fibre system as revealed in ammoniacal silver impregnation and in histochemical enzyme studies of normal guinea pig hippocampi Functional elucidation should be forthcoming soon through the electron-microscopic, and more detailed enzymic, investigation of such experimental pathological states as described above From my further explorations of the effects of varied post-mortem delay in guinea pigs, there would seem to be no reason why the silver sulphide method should not be applied, experimentally or clinico-pathologically, to large mammals provided the brain, or biopsy therefrom, be reduced to room temperature within about 1 h after death

Effect of Tobacco Diets on Rodents

THE habit of chewing snuff or tobacco has been associated in human beings with the occurrence of leukoplakia and cancer of the buccal mucosa[1,2] In India, the chewing of dried and earth-cured tobacco along with betel nuts and slaked lime has been linked with oral cancer[3,4] Differences in incidence of cancer for various communities occurs according to the site at which tobacco mass is kept in the mouth The investigations on mice and rats recorded here show the effects of direct contact of tobacco with the buccal mucosa and effects on those organs responsible for its degradation

Male Wistar rats 6 weeks old and male mice 2 months old were fed commercially available tobacco products mixed with ground 'Purina' diet Control animals were fed ground 'Purina' chow without tobacco All animals were weighed monthly The mice and rats were killed after being on the experimental diets for 15 months and 18 months respectively

For the cigarette experiments the cigarette paper was removed and the tobacco dried on metal trays and then mixed with ground 'Purina' chow The ratio, by weight, of tobacco from low nicotine cigarettes to food was 1 25 for mice, for rats it was 1 25 for 3 months, then changed to 1 30 for the remainder of the experiment Rats were also fed tobacco from a mixture of popular brands in a ratio of 1 25

Both mice and rats were fed snuff Fresh commercial snuff was dried in a vacuum desiccator until the 1¼ oz contents of one can weighed 19 g This dried snuff was mixed with finely ground food The rats were fed snuff in a ratio of 1 20, by weight, while the mice were fed snuff in a ratio of 1 4 for one month, 1 9 for 4 months and 1 18 for the remaining 13 months

Table 1 presents the number of animals constituting the various experimental groups as well as the number which remained when the experiments were terminated The final average weights for rats on experimental diets were significantly lower than the controls (0 05 level) and show a dose response pattern, indicating that snuff diet caused the greatest loss in weight followed by regular cigarette mixture and low nicotine cigarette mixture Throughout the experiment, mice on the snuff diet gained less weight than controls The difference in final weight was statistically significant (0 05 level) for *DBA* mice but not the $C_{57}B1$ mice

Table 1 MEAN AND STANDARD ERRORS OF FINAL WEIGHTS OF SURVIVING ANIMALS

Animals	Tobacco diets			Controls
	Snuff	Regular tobacco	Low nicotine tobacco	
Wistar rats	(16/40)* 235 ±13 8†	(17/31) 366±17 4	(22/34) 408 ±11 8	(31/32) 441 ±9 9
DBA mice	(23/34) 24 3± 0 42	—	(44/44) 26 3± 0 30	(17/17) 28 0±0 51
$C_{57}B1$ mice	(16/16) 24 7± 0 69	—	—	(20/20) 26 6±0 73

* Survivors/original group
† Average final weight of survivors

Survival of rats indicates a highly statistical significant trend (0 01 level) in toxicity corresponding to trend of weight reduction Snuff diet had a less-pronounced effect on survival of *DBA* mice, but survival was nevertheless significantly lower than control (0 05 level) These results are similar to those observed among regular smokers in human populations[5]

Animals were autopsied and histological sections of grossly abnormal tissue were studied Few pathological changes were noted Four rats which were fed snuff had interesting changes consisting of one leucocytic leukæmia, one kidney sarcoma and two with superficial ulcers of stomach mucosa Four rats given tobacco from popular cigarettes had chronic passive congestion of the liver Bronchiectasis was found in almost equal incidence in the low-nicotine tobacco group of rats and in control animals This observation had been previously reported and related to the ageing process of rats[6,7] Twenty-three mice, mostly *DBA*, on the snuff diet had nephritis as compared to 2 animals in the control group Calcareous pericarditis was found in 9 *DBA* experimental animals and 1 control, however, this lesion has been reported to occur spontaneously in *DBA* mice[8] Three *DBA* mice had leukæmia involving liver and kidney Tumours are known to occur spontaneously in these animals, but none was observed in the controls for these experiments The most striking abnormality found in *DBA* mice fed low-nicotine tobacco was the lip papilloma in 3 mice No malignancy developed, and all three eventually shed the growth Histological examination revealed that the stomachs of two mice on this cigarette diet showed hyperplastic gastric mucosa, a condition often found in human beings who smoke

In comparison with control groups, rodents fed unsmoked tobacco products reached and maintained significantly lower weight There is a reduction in the amount of food which the animals consume This has also been true of animals exposed to cigarette smoke or nicotine[4] The effect on weights and survival may be due to a combination of toxicity coupled with the possible appetite depressant action of nicotine This latter concept would tend to explain the less-pronounced effect of the low-nicotine tobacco cigarettes which are made from leaves that naturally have a low level of nicotine

RADIOBIOLOGY

Tumour Development in the Rat induced by Blood of Irradiated Animals

EXPERIMENTS are being carried out to ascertain whether the incidence of tumours in non-irradiated animals can be influenced by the introduction into the body of fluids or tissues from irradiated donors This communication reports preliminary results from a three and a half year study of rats injected with blood plasma or with blood plasma ultra-filtrate from irradiated rats and sheep

Blood plasma was obtained separately from (*a*) lethally irradiated rats, (*b*) normal rats, (*c*) lethally irradiated sheep, (*d*) normal sheep Blood was collected over versene (sodium ethylenediamine tetraacetic acid, Na_2EDTA) under sterile conditions from ether-anæsthetized rats via the cava vein Samples from several animals were pooled and the plasma obtained by centrifugation Sheep blood was obtained without anæsthesia from immobilized animals through jugular venipuncture, collected in closed sterile plastic bags on Na_2EDTA, and the plasma expressed from the bags after being centrifuged The plasma samples of both rats and sheep were freeze-dried and kept at 4° C until used (not more than 4 days) The sheep plasma in addition was ultra-filtered in cold (cellulose dialysis tube, 'Visking') before being frozen Before injection, rat plasma was re-constituted to twice and sheep plasma ultra-filtrate to twenty times the original concentration

Animal species irradiated with cobalt-60 γ-rays were (*a*) adult Sprague-Dawley rats of both sexes, 1,250 r at 7 72 r /min, (*b*) adult grade Hampshire sheep, female or castrate male, 1,610 r at 0 95 r /min

Rats were injected intraperitoneally at 7 days of age with 0 2 ml of concentrated blood plasma from (1) irradiated and (2) normal rats the treatment was repeated on days 9 and 14 Of 126 rats in group 1, 50 died, as did 28 of 79 in group 2 There was no difference in mortality-rate between groups (In further experiments now in course, a much lower mortality was observed in rats injected with blood plasma from irradiated or from normal donors) When concentrate plasma ultra-filtrate from irradiated or normal sheep was used (as was also the case with physiological saline), new-born rats were injected in the heart cavities when less than 24 h old with 0 05 ml and again 7 days later, afterwards they were injected intraperitoneally at 12, 17, and 21 days of age with 0 3 ml each time Of 129 animals receiving intracardial and intraperitoneal concentrated plasma ultra-filtrate injections from irradiated or normal sheep, only 19 died, about the same mortality-rate as when saline was used Survivors weaned at 21 days of age were fed with Purina Laboratory Chow and water *ad libitum* Animals receiving blood plasma or blood plasma ultra-filtrate were observed for tumour development during their life-span, none of these animals was bred (Occasionally some rats in all of the groups developed incisors so long that to avoid death by starvation partial cutting of these teeth was required)

The differences between proportions were estimated using 95 per cent confidence intervals as the criteria to compare the tumour incidence among the groups

Female rats which received either blood plasma from irradiated rats or blood plasma ultra-filtrate from irradiated sheep showed a significant increase of tumours when compared with those injected with normal plasma or with physiological saline (Table 1) Tumour incidence in male rats showed no significant differences between the groups The time in which the first appearance of the tumour was noted was not significantly different between females injected either with plasma or ultra-filtrate and irradiated and normal animals (Table 2)

Table 1 Tumour development in rats injected with blood plasma from irradiated rats (Plasma, *I*), blood plasma from normal rats (Plasma, *N*), concentrated plasma ultra-filtrate from irradiated sheep (Ultrafiltr , *I*), concentrated plasma ultra-filtrate from normal sheep (Ultra-filtr , *N*), and physiological saline (Saline) F, Females, M, males

Table 2 Time at which rat tumours were first observed after being injected with blood plasma (rat) and blood plasma ultra-filtrate (sheep)

Plasma characteristics	No of rats		First tumour observation (range in days)	
	F	M	F	M
Plasma, irradiated	61	15	158–1,007	630–1,213
Plasma, normal	33	18	835–1,118	510–1,057
Ultrafiltr , irradiated	30	25	692–912	787–845
Ultrafiltr , normal	30	25	701–903	751–863
Saline	30	35	716–868	767–831

The histology of the tumours has not shown appreciable difference in the relative frequency of each particular type between the groups injected with plasma or with ultra-filtrate from irradiated or from normal animals, either in females or males In female rats 40 per cent of the tumours of the mammary gland were adenomata, the remainder being about equal proportions of fibroadenoma, fibroma, fibrosarcoma, and adenocarcinoma Tumours other than mammary were rarely observed in the female rat under conditions of the experiment In male rats tumours were mainly squamous papilloma, cavernous hemangioma located subcutaneously in the escapular or thoracic regions, and squamous carcinoma of the malar region with some fibrosarcoma and adenofibroma at various sites

Both incidence of tumour in males and their histological type were not apparently different from those spontaneously arising in the rat colony

Although the number of rats used in these experiments is rather small the incidence figure, as herein recorded, shows that blood plasma from irradiated animals (rats) and plasma ultra-filtrate (sheep) are capable of increasing the frequency of breast tumour in the female rat Explanation for this, other than the presence in the blood of irradiated animals of one or more tumorogenic substances or of factors potentiating the onset of mammary tumours, is difficult to conceive However, in virgin female Sprague-Dawley rats kept in this colony during their life span, the spontaneous incidence of mammary tumours has been about 55 per cent Howell and Mandl[2] found in rats of the Birmingham strain the incidence of spontaneous mammary tumours ranging from 49 per cent in nulliparæ females to 4 per cent in multiparæ Because of this high incidence, it appears that the possibility of other non-specific factors which may increase the number of rats with tumours cannot be excluded in any tumorogenic experiments with the Sprague-Dawley rats Shellabarger *et al* [3] observed a 90 per cent incidence of neoplasia of the mammary gland in female Sprague-Dawley rats exposed to total-body cobalt-60 γ-irradiation at 40 days of age and examined until death Mammary tumours may be induced in a high percentage of female rats by aminofluorene compounds, carcinogenic hydrocarbons, growth hormone, and œstrogens[4] Comparison of mammary tumours developed using blood from irradiated animals and with carcinogens is not possible at this time The incidence and type of breast tumour differ with the nature of the carcinogen, dose and route of administration, age of the animal at the time at which the carcinogen is given, diet, and the hormonal status of the rats[5–7] At the present time we have no adequate explanation for the reduced tumour incidence in female rats injected with saline

Development of mammary tumours in male rats injected with blood plasma of irradiated animals is not significantly different from that in males injected with normal blood plasma Lack of evidence exists, too, regarding male rats treated with carcinogens[6–8]

Tumours as developed in untreated Sprague-Dawley female rats are primarily mammary, other types amounting to only 5 per cent[5] It is not known at present whether tumours other than of the breast could be formed or potentiated by irradiated blood plasma or blood plasma ultra-filtrate in rats of other strains or in other animal species

IMMUNOLOGY

Immunological Significance of the Thymus of the Adult Mouse

MICE thymectomized in neonatal life have shown a marked deficiency of small lymphocytes in the peripheral blood, spleen, lymph nodes and Peyer's patches[1–3] and a depression of the immune response to both viral and bacterial antigens[4] and to allogeneic[1,2,4,5] and even heterospecific[2,4] skin grafts Mice thymectomized after 3 weeks of age have not shown any significant depression of the immune response to foreign skin grafts nor any marked reduction in the lymphocyte population[1,2,4] These observations have suggested the hypothesis[1] that during embryonal and early neonatal life the thymus produces the progenitors of immunologically competent cells which mature and migrate to other sites, alternatively, it would produce a humoral factor essential for the maturation and proliferation of lymphocytes throughout the body during development Evidence from this laboratory, summarized below, suggests that the function of the thymus in initiating immunogenesis is not necessarily restricted to early life

Table 1 EFFECT OF THYMECTOMY IN ADULT LIFE ON THE FORMATION OF SHEEP RED CELL AGGLUTININS FOLLOWING SUBLETHAL IRRADIATION

Treatment	No of mice in group	No of mice with following log₂ titre agglutinins* 0	1	2	3	4	5	6
Thymectomized, irradiated, injected with sheep red cells	6	2	1	2	0	1	0	0

Sham-thymectomized, not irradiated, injected with sheep red cells	12	0	0	1	1	3	4	3
Not thymectomized, not irradiated, not injected	10	10	0	0	0	0	0	0

* Serum titrated 7 days after injection of red cells

Table 2 EFFECT OF THYMECTOMY IN ADULT LIFE ON RECOVERY OF IMMUNE RESPONSE TO SKIN HOMOGRAFTS FOLLOWING SUBLETHAL IRRADIATION

Treatment	No of mice in group	Donor skin	No of mice showing skin graft survival for < 20 days	20–50 days	> 50 days
Thymectomized, irradiated	16	*C3H*	1	0	15
		C57BL	2	10	4
Thymectomized, sham-irradiated	18	*C3H*	18	0	0
		C57BL	18	0	0
Sham-thymectomized, irradiated	16	*C3H*	15	1	0
		C57BL	16	0	0
Sham-thymectomized, sham-irradiated		*C3H*	10	0	0
		C57BL	10	0	0

Twelve-week-old F_1 hybrid mice from a cross between *Ak* and *T*6 were thymectomized or sham-operated and given a single dose of total body irradiation of 350 r two weeks later They were challenged four weeks after irradiation with either sheep red cells or skin grafts from both *C3H* and *C57BL* donor mice The results are shown in Tables 1 and 2 It will be seen that a single dose of 350 r following thymectomy in adult life was associated with an impairment of the ability to recover the capacity for an immune response to both sheep red cells and skin homografts Furthermore, the impairment was long lasting in the case of grafts from donors closely related immunogenetically to the host It is possible that at higher levels of total-body irradiation exposure the impairment would have extended to grafts from donors distantly related to the host The thymus in adult life appears, therefore, to be essential for complete recovery of the immune mechanism following sub-lethal irradiation.

There is one cytological feature common to the thymus in neonatal life and the thymus regenerating in the adult animal after acute involution induced by such agents as irradiation[6] There is in the cortex of the normal thymus of the neonatal mouse a zone of immature, large lymphocytes with a very high mitotic index During the first two weeks of life, the immature cells in this zone differentiate rapidly and by three weeks of age the cortex is composed predominantly of mature small lymphocytes[7] During regeneration of the thymus following irradiation in the adult, the cortex resembles that of the neonatal thymus in showing a striking prevalence of immature lymphoid cells It is perhaps more than a mere coincidence that circumstances which prevent this lymphoid cell differentiation sequence from taking place both in neonatal and in adult life should be associated with deficiencies in the immune mechanism Results obtained with cytologically marked thymus grafts in neonatally thymectomized hosts indicate that some type of host cells (stem cells) invade the thymus graft and find in it an environment suitable for lymphoid cell differentiation and multiplication[4] The thymus-grafted animal eventually regains full immunological competence[1,2,4] Unlike thymus grafts, injection of dissociated thymus cells from neonatal donors into mice thymectomized at birth has failed to establish a properly functioning immune system[2] One therefore wonders whether the thymus initiates immunogenesis, not by actually generating, *ab initio*, the progenitors of immunologically competent cells, but by providing the environment wherein cells can differentiate and acquire the capacity for immunological competence The mechanism whereby this occurs, whether by direct cell to cell interaction, or by the elaboration of some specific humoral-like maturation factor by non-lymphoid thymic cells, is not known

I thank Prof Alexander Haddow for his interest in this work and Dr S M A Doak for help with some of the techniques used The investigations were supported by grants to the Chester Beatty Research Institute (Institute of Cancer Research Royal Cancer Hospital) from the Medical Research Council, the British Empire Cancer Campaign, the Anna Fuller Fund and the National Cancer Institute of the National Institutes of Health, U S Public Health Service They also received special support through a grant from the Tobacco Manufacturers Standing Committee

Non-Antigenicity of Synthetic Polyribonucleotides and Apurinic Acid

THE antigenicity of nucleic acids is a subject which has been extensively explored Much of the information available is clouded by the fact that the materials used were contaminated with protein and other cellular constituents so that the specificity of the antigen–antibody reactions observed has been unclear[1] Recently, however, two facts have emerged which leave little doubt as to the ability of nucleic acids to participate in immunological reactions The first is the observation that T_2, T_4 and T_6 phage DNAs, when highly purified, are capable of interacting with antisera prepared by inoculation of animals with whole phage lysates[2] The antigenicity of these DNAs depends upon the presence of glucosylated 5-hydroxymethylcytosine[3,4] Secondly, the sera of certain patients suffering from lupus erythematosus contain antibodies capable of reacting with native or denatured DNAs of diverse source[5,6] The antigenic site for this interaction appears to involve regions of the DNA molecule where thymine occurs in repetitive sequence[7]

In order to explore further the problem of the antigenicity of polynucleotides, attempts were made to immunize rabbits with the synthetic polynucleotides polyadenylic, polyuridylic, polycytidylic, and polyinosinic acids These homopolymers were prepared from the appropriate nucleoside diphosphates using a polynucleotide phosphorylase derived from *M lysodeikticus*[8] and were virtually protein free In addition, attempts were made to immunize rabbits with apurinic acid[9] derived from commercially obtained beef thymus DNA (Sigma Chemical Co) Two animals were used for each polynucleotide An initial injection of material emulsified in complete Freund's adjuvant was followed by 3 weekly series of 3 injections in saline, each animal receiving a total of 7 5–10 mg of polynucleotide The animals were bled 7 days after the last injection, and the sera were examined for the presence of antibody by the following methods Ouchterlony double diffusion in agar gel, Oudin single diffusion in agar gel, complement fixation, and classical immunoprecipitin techniques In all cases the results were entirely negative

Synthetic homopolynucleotides were used in this experiment because they are substances which do not occur in Nature, and it was hoped that, like certain synthetic polypeptides, they would have antigenic properties Highly purified T_2 phage DNA has been shown to be incapable of producing antibodies when used as the immunizing material *per se*[10] Methods are therefore being sought of combining polynucleotides with effective protein antigens such as bovine serum albumin in the hope that such a material will be effective in eliciting an antibody capable of interacting with the pure polynucleotides

BIOLOGY

Breakdown and Synthesis of Cell Walls during Growth

PLASTIC extension of the primary wall in enlarging plant cells is thought[1–3] to require relaxation of the interwoven structure of the pre-existing wall as well as deposition of new wall materials It is possible that relaxation of the old wall, which has usually been attributed to fibre re-orientation, could also be facilitated by the breakage of bonds This communication deals with the reality of wall catabolism and the extent to which it and wall anabolism are correlated with growth All work was carried out with sections excised (as in Fig 1) from the third internode of 8-day-old etiolated pea epicotyls (*Pisum sativum* L var Alaska)

In preliminary tests sections were incubated on water, with no sugar supplied in order to minimize wall synthesis, and comparisons were made between changes in fresh weight and in the ethanol- and ether-insoluble dry weight The results after 2 days incubation are recorded in Table 1 Sections cut from the upper part of the epicotyl grew slowly but at the same time lost up to one quarter of their insoluble dry weight, while sections cut 1 cm or more below the apical hook did not enlarge yet gained in dry weight The insoluble fractions contain chiefly wall

Table 1 GROWTH AND INSOLUBLE DRY WEIGHT CHANGES IN PEA EPICOTYL SECTIONS FLOATED ON WATER FOR 48 HR

Section*	Change in fresh wt (%)	Change in dry wt (%)
H	+ 6	−27 4
1	+60	−22 9
2	+40	− 9 2
3	+15	+ 4 9
4	+18	+10 7
5	+ 6	+15 5

*Sections cut and extracted as in Fig 1

polysaccharides and nitrogenous materials Apparently the amounts of the latter increase during the growth of pea epicotyl sections, even on water[4], in which event it must be concluded that breakdown and dissolution of the wall can occur in young tissues, if not in those that have ceased enlarging

In the following experiment, sections were grown for 24 hr on 2 per cent sucrose uniformly labelled with carbon-14 in order to provide a substrate for the wall synthesis that normally accompanies cell expansion Fig 1 shows the insoluble dry weights of sections measured before (curve I) and after (curve II) incubation Under these conditions growth was more rapid than on water and was confined to the basal end of the hook and the apical cm of epicotyl shaft In section 1 length increased by 60 per cent and fresh weight by 105 per cent whereas in section 5 length increased by 4 per cent and fresh weight not at all

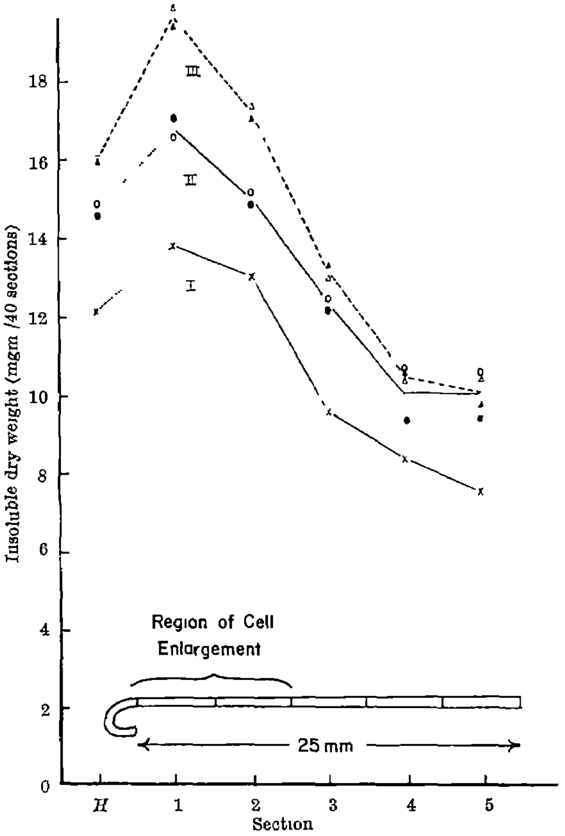

Fig 1 Insoluble dry weights of the hook (*H*) and successive 5 mm sections cut from etiolated pea epicotyls Curve I, weights at zero time, Curve II, weights of duplicates (40 sections each) grown in darkness at 26±1° C for 24 hr on 3 ml 2 per cent ^{14}C-sucrose in 0 01 *M* phosphate buffer, *p*H 6 0, Curve III, weights at zero time plus weights of incorporated ^{14}C-sucrose Weights of sections were measured after 5 half-hr extractions with 15 ml hot 80 per cent ethanol alternating with 5 half-hr extractions with hot absolute ethanol, followed by a 2-day extraction with ethyl ether and a 10-day drying period over calcium chloride *in vacuo* Weights of incorporated ^{14}C-sucrose were calculated as the insoluble c p m divided by specific activity of the substrate (1,990 c p m /mgm)

The growth pattern did not correlate with dry weight increments since these were approximately the same in all sections

Table 2 records the total amounts of radioactivity incorporated into insoluble fractions, as determined by counting powdered and weighed samples in air with a Geiger tube Chromatographic analyses of acid hydrolysates of these fractions revealed that the major radioactive components were aldo-sugars and uronic acids No fructose appeared in any hydrolysate so that none of the radioactivity was present as adsorbed sucrose Accordingly, the levels of radioactivity in the sections closely represented the relative amounts of wall polysaccharide derived from ^{14}C-sucrose Deposition was greatest in those sections that enlarged most, but these were also the sections with the greatest initial dry weights (Fig 1) and, in fact, the extent of wall synthesis was roughly proportional to the amount of pre-existing wall

Table 2 INCORPORATION OF ^{14}C-SUCROSE INTO CELL WALLS AND RESPIRED CARBON DIOXIDE

Section*	Radioactivity in cell walls (c p m /40 sections)	$\frac{\text{Specific activity CO}_2}{\text{Specific activity } ^{14}\text{C-sucrose}} \times 100$
H	8,320	79
1	12,230	79
2	8,780	74
3	7,460	72
4	5,000	63
5	5,290	66

*Details of experiment in Fig 1

Values are plotted in Fig 1, curve III for the initial dry weights of the sections plus weights of the incorporated ^{14}C-sucrose If there had been no breakdown of insoluble material during the experiment these values should have been attained (or exceeded) by the final dry weights (curve II) Curves II and III coincide fairly well in the basal three sections, however, in the apical sections much more wall polysaccharide was formed than could be accounted for by the increments in dry weight For example, the 13 mgm dry weight of section 1 incorporated about 6 mgm of ^{14}C-sucrose, but increased in dry weight by only 3 mgm Evidently, at least one-fifth of the original insoluble material dissolved in the growing regions at the same time as new wall was being formed Dissolution may not have occurred at all in sections that did not grow

It seems doubtful whether any one wall component could account for such extensive dissolution, particularly since the values for wall breakdown indicated in Fig 1 are minimal values Consideration should be given to the decorporation of radioactive wall material, which undoubtedly occurs in such experiments[5-7], and to additional wall synthesis from unlabelled endogenous substrates The extent to which the latter would increase the recorded discrepancies between wall formation and weight increment may be calculated if it is assumed that substrates for wall synthesis and respiration were derived from the same metabolic pool Since respired carbon dioxide was 65–80 per cent as radioactive as the supplied ^{14}C-sucrose (Table 2), the values for total wall synthesis would be greater than those shown in Fig 1 by the reciprocal of these percentages Applied to section 1, this calculation leads to the conclusion that about one-third of the original insoluble material dissolved during the experiment

It is therefore proposed that extensive breakdown of pre-existing wall, rather than synthesis of new wall, be regarded as an essential feature of plasticization in enlarging cells During growth, new wall material is intercalated in amounts which, depending on substrate availability, may or may not replace the materials dissolved

Nitrogen Status of the Carnation Plant

A low level of nitrogen given under short-day conditions has been shown to delay flower initiation in the carnation[1] Though a slower growth-rate was observed under these conditions, the plants, unexpectedly, did not show typical symptoms of nitrogen deficiency Further work has shown that the nitrogen content of plants grown in sub-irrigated sand culture bears little relation to the level of nitrogen in the nutrient solution Under conditions of low nitrogen supply, considerably more nitrogen was found in the plants than was supplied in the nutrient solution

Experimental details were similar to those described previously[1] The plants were given either short-day (8 h) or long-day (17 h) treatment at two temperature-levels, the higher being maintained at about 15° C and the lower at about 10–12° C The plants were grown in sub-irrigated sand culture with nitrogen levels, supplied as nitrate, of 5 p p m , 15 p p m and 45 p p m Each nitrogen treatment was replicated four times within a daylength-temperature treatment, and the basic unit was two plastic pots 9 in in diameter connected to a single nutrient reservoir holding 4 l of solution One pot of each pair held four cuttings of the variety Puritan and the other held two cuttings of the variety White Sim A single axillary shoot from each cutting was taken to anthesis Estimations of the nitrate content[2] were carried out on the initial solution, and at intervals on the solution in the reservoirs As soon as the solution became out of the range 2–8 p p m for the 5 p p m solution, 12–18 p p m for the 15 p p m solution, and 40–50 p p m for the 45 p p m solution, the reservoir was refilled with fresh solution The total nitrogen content of the whole plants at anthesis was determined by the Kjeldahl method

Despite the low levels of nitrogen supplied, the plants did not show severe nitrogen deficiency symptoms in any of the treatments Table 1 shows that the total nitrogen, expressed as a percentage of the dry weight of the plants, was only slightly affected by the level of nitrogen supplied The growth-rate was primarily affected by daylength and temperature, and to a smaller extent by nitrogen level, as is shown by the ratio of the time to appearance of the flower buds to the number of leaf pairs below the bud (Table 1) The total amount of nitrogen found in the plants is shown in Fig 1 Regardless of the level of nitrogen supply, all plants under long days contained similar amounts of nitrogen, but under short days the amount of nitrogen in the plants increased with an increasing level of nitrogen supply At 5 p p m of nitrogen the plants contained nearly five times as much nitrogen as was removed from the nutrient solution, and at 15 p p m nitrogen approximately twice as much, whereas at 45 p p m nitrogen there was little difference In the calculation of nitrogen uptake no allowance was made for the amount of nitrogen present in the original cutting, but this was approximately compensated by the removal of all but one axillary shoot, this material being equivalent in size to the original cutting No account was taken of other sources of nitrogen, such as ammonia in the tap water These errors are admitted, but they could only account for a very small portion of the treatment differences observed

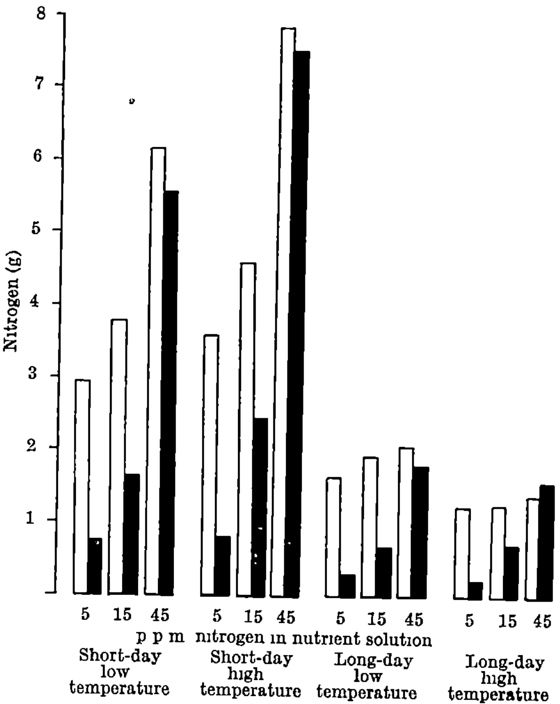

Fig 1 Total nitrogen found in plants (white) and removed from nutrient solution (black) Each histogram represents a total of 24 plants (16 var Puritan, 8 var White Sim)

Despite suggestions that higher plants may be able to fix atmospheric nitrogen[3,4], the results given here are probably best interpreted on the assumption that nitrogen-fixing organisms were present in the sand,

and that they were active to a proportionately greater extent in the low nitrogen treatment. The results show that in experiments using tap water, and possibly also where distilled water is used, the level of nitrogen present in the plant does not necessarily bear a relation to the amount supplied to the plants in the nutrient solution, and may explain why few workers have been able to detect an effect of nitrogen nutrition on flower initiation.

Promotion of Cell Wall Synthesis by Indolylacetic Acid

It is widely believed that the increase in cell wall synthesis which occurs when growth of plant cells is promoted by auxin is neither a direct consequence of hormone action nor a causal factor in cell enlargement, but is induced indirectly by the occurrence of cell enlargement[1]. A principal reason for this view is that if elongation is inhibited osmotically by mannitol, wall synthesis becomes reduced[2], and promotion of wall synthesis by auxin does not occur[3].

Table 1 compares the effect of 3 mg/l. indolylacetic acid (IAA) on cell wall synthesis in oat coleoptile segments: (*a*) when no inhibitor is present and elongation occurs; (*b*) when elongation is inhibited by 0.25 M mannitol; (*c*) when elongation is inhibited by 0.01 M calcium chloride, which is considered to prevent elongation by making the cell wall more rigid[4]. Segments 8 mm long were cut from coleoptiles of 3-day-old oat seedlings, var. Victory. Groups of eight segments were floated in 1.0 ml. of 0.05 M glucose containing 1.67 μc. of glucose uniformly labelled with carbon-14, on a reciprocating shaker at 120 oscillations per min. in the dark. After 7 h the segments were washed with water, measured and placed in 1 ml. of 80 per cent ethanol to extract soluble radioactivity. Segments were then crushed between glass plates (as described in ref. 5), and extracted with 0.2 per cent crystalline pepsin in 0.03 M phosphate buffer, *p*H 2, for 24 h to remove protein. The insoluble residues, representing cell wall material, were dried on planchets and counted with 25 per cent efficiency. Absorbed activity, as given in Table 1, is the sum of extractable activity and activity incorporated into the cell wall material.

When elongation is not inhibited, IAA causes a large increase in wall synthesis, as has been found previously (ref. 5, and literature cited there). This is associated with an increase in uptake of glucose, but the percentage of the absorbed glucose which is incorporated into the cell wall is nevertheless increased substantially by IAA.

In the presence of 0.25 M mannitol, no promotion of cell wall incorporation by IAA can be demonstrated, in agreement with earlier findings[3].

However, when elongation is inhibited instead by calcium ions, a conspicuous promotion of cell wall incorporation by IAA is observed, associated with no increase in uptake of activity. A similar IAA promotion of incorporation in the presence of calcium ions can be demonstrated in *p*H 4.5 maleate buffer, so the effect does not appear to be due to differences in *p*H.

Table 1. EFFECT OF IAA ON CELL WALL SYNTHESIS

Inhibitor	IAA	Length (mm.)	Cell wall activity (c.p.m.)*	Absorbed activity (c.p.m.)*	Percentage incorporated†	IAA effect‡
None	–	9.2	8,470 ± 820	55,420 ± 3,970	15.3 ± 0.9	
	+	11.8	14,540 ± 410	68,450 ± 4,290	21.2 ± 0.9	1.38
Mannitol	–	8.8	6,000 ± 780	48,540 ± 5,440	12.4 ± 1.2	
	+	8.7	5,460 ± 200	42,830 ± 2,850	12.7 ± 0.8	1.03
$CaCl_2$	–	8.7	7,540 ± 90	43,760 ± 1,480	17.3 ± 0.8	
	+	8.8	10,760 ± 130	43,120 ± 3,210	25.0 ± 1.6	1.44

* Mean and average deviation for 4 replicate samples each consisting of four coleoptile segments.

† Percentage of absorbed activity which was incorporated into cell wall.

‡ Percentage of incorporation in presence of IAA, divided by percentage incorporation in absence of IAA.

The experiment with calcium ions shows that auxin has a promotive effect on cell wall synthesis which is direct in the sense that it is not a result of the effect of auxin on elongation. That IAA promotion cannot be detected when elongation is inhibited by mannitol indicates that mannitol inhibits this action of IAA on wall synthesis.

Relative to uptake of glucose, the promotion of wall incorporation by IAA in the presence of calcium ions is similar to the IAA promotion which is observed in the absence of inhibitor, when rapid elongation is occurring (Table 1, last col.). We presume, therefore, that the same direct IAA promotion is operating during elongation, but is being added to by an indirect effect which may result from elongation and is associated with an increase in uptake of glucose.

The promotion of total wall synthesis by IAA in the presence of calcium ions is, by per cent, comparable with the promotion of hot water soluble pectin synthesis by IAA, which has been emphasized as involved in the action of auxin on elongation[6]. While hot water soluble polyuronides constitute less than 1 per cent of the cell wall, the presently described promotion involves cell wall synthesis as a whole and is, therefore, a gross effect compared with that on pectin. It is due mainly to increases in incorporation of sugar constituents of the cell wall material rather than uronic acids. Detailed information on the effect of IAA on incorporation into individual constituents will be published elsewhere.

The magnitude of the effect of IAA on cell wall synthesis, demonstrable in the presence of calcium ions, suggests that this effect could be causally related to the effect of IAA on elongation. This possibility will be explored.

The Life of Vertebrates

SECOND EDITION

J. Z. YOUNG

This new edition has been completely revised by the author. As much as possible of the fresh work done since the first edition was published in 1950 has been incorporated To do this for anatomical, physiological, and palaeontological matters has involved some changes of form and many new illustrations. However, the main form of the original work has been retained since it has proved to be a good means of teaching the subject. Attention is directed to as many aspects as possible of the life of each animal or group The problems involved in each type of study are discussed as they arise, in an attempt to teach the student to look for new points of view while learning to organize and assimilate the facts at the same time. *Numerous text-figures 70s net*

'This is perhaps the best textbook of vertebrate zoology that has yet been written, and as there are already several good textbooks on the subject, this distinction has not been easily achieved.' NATURE, *reviewing the first edition*

ORTE

Does Maternal Immunity to Male Antigen affect the Sex Ratio of the Young ?

Renkonen, Makela and Lehtovaara[1], in a study of human sex ratio, report that the birth of a boy renders a woman less likely to give birth to further boys in the future In other words, the greater the number of boys born previously, the lower is the sex ratio (expressed as the number of boys born for every 100 girls) at a given parity The authors suggest that bearing a male fœtus may immunize some women against male (*Y*) antigen, and that this immunization may harm subsequent male fœtuses The possibility also exists that a female immunized against *Y* antigen might inactivate a proportion of *Y*-bearing sperm before fertilization

I have put to an experimental test in mice the hypothesis that immunization of a female to *Y* antigen will affect the sex ratio of her offspring Female mice of the *C57BL* inbred strain were subjected to one of the following treatments

(1) 3 intraperitoneal injections per week for 7 weeks of half of a *C57BL* ♂ spleen (60–90 million cells per dose) suspended in *tris*-buffered saline, (2) similar injections of one-sixth of a *C57BL* ♂ spleen (20–30 million cells per dose), (3) similar injections of sperm from the vasa deferentia of a *C57BL* ♂ (about 30 million sperm per dose), (4) weekly subcutaneous injections of *C57BL* ♂ spleen in Freund's adjuvant (about 40 million cells per dose), (5) grafted with skin from *C57BL* male

The effect of these treatments on the immune state of the females was tested by grafting them with *C57BL* male skin In untreated females of my *C57BL* colony, survival time of isologous male skin grafts ranged from 14 to 73 days (Table 1) Survival-time was expressed as the time from grafting to the first sign of scabbing of the graft, since the day of final breakdown of the graft is difficult to assess where breakdown occurs slowly Table 1 shows that all treatments, except the first, produced some degree of immunity as judged by accelerated graft breakdown The first (repeated injections of spleen cells, half a spleen per dose) produced a state of tolerance, or immunological unresponsiveness, all grafts surviving for at least five months and showing a vigorous growth of hair That unresponsiveness should have resulted from the repeated injections of relatively large amounts of male spleen cells is not surprising in the light of previous reports[2,3] on the ease with which tolerance to the very weak *Y* antigen can be induced, even in adults On the other hand, the narrow margin between the dosages needed to confer immunity or tolerance is striking

The clear indication of immunity in the two females injected with sperm suggests that sperm contain *Y* antigen The sperm suspensions were contaminated with small numbers of other cell types (erythrocytes, epithelial cells from the vas deferens), but it does not seem likely that these would have been abundant enough to induce immunity

The serum of females injected with male spleen cells was tested for circulating antibody using agglutination tests against *C57BL* male erythrocytes and sperm, indirect agglutination tests (with the aid of an anti-mouse-globulin serum prepared in rabbits) against *C57BL* sperm, and cytotoxic tests[4] against *C57BL* male spleen cells All were negative In contrast, the sera of females injected with sperm showed a high titre (> 1/4,096) of sperm agglutinins, non-specific in the sense that the sera agglutinated sperm from males of other strains as readily as they did *C57BL* sperm Similar findings have been reported previously[5,6]

Table 1 TIME OF APPEARANCE OF FIRST SCAB AFTER GRAFTING *C57BL* MALE SKIN ON TO ADULT *C57BL* FEMALES

Group	No of mice	Time (days)	Immune status
Untreated	16	14 14 14 15 20 22 25 26 26 28 30 34 38 53 59 73	
Repeated injections of ½ ♂ spleen	4	>150 >150 >150 >150	Tolerance
Repeated injections of ⅙ ♂ spleen	6	11 11 11 12 14 14	Immunity
Repeated injections of sperm	2	11 12	Immunity
Repeated injections of ♂ spleen with adjuvant	8	12 12 13 13 13 15 17 19	Weak immunity
Previous skin graft	8	11 11 11 11 12 12 12 14	Immunity

Table 2 SEX RATIO AND MEAN LITTER SIZE OF YOUNG OF TREATED *C57BL* FEMALES

Group	No of litters	♀	♂	Mean litter size
Repeated injection of ½ ♂ spleen	4	11	12	5 7
Repeated injection of ⅙ ♂ spleen	6	24	18	7 0
Repeated injection of sperm	2	2	1	1 5
Repeated injection of ♂ spleen with adjuvant	8	21	19	5 0
Previous ♂ skin graft	8	21	26	5 9
Neonatal injection of ♂ spleen cells	8	27	26	6 6

Two to three weeks after the test grafts had been made all treated females were mated to *C57BL* males The first litter from each was sexed at birth In control matings of comparable age, mean litter size at birth was 6 6 young, and sex ratio did not depart significantly from equality The immune females (the state of immunity of which would have been increased as a result of the test grafting) showed no significant deviations from the control level either in litter size or sex ratio of young (Table 2) with one exception, that is, the two females injected with sperm, both of which had abnormally small litters This raises the interesting possibility that the high titre of sperm agglutinins demonstrated in the serum may have exerted a depressing effect upon fertility

Also included in Table 2 is a group of 8 *C57BL* females rendered tolerant to *Y* antigen by neonatal injection of *C57BL* male spleen cells It has been suggested that the implantation of embryos in the mammalian uterus has an immunological component, involving histocompatibility differences between fœtus and mother In two inbred strains of mice, Fekete[7] found a higher rate of implantation among embryos transferred to the uteri of females of the other strain than among within-strain transfers The existence of inbred strains, isogenic for all known histocompatibility loci, does not necessarily refute this theory, since the mother will always lack *Y* antigen and this may need to be present in the embryos or sperm before an implantation reaction can take place However, since in the present study litter size was normal in the highly inbred *C57BL* females rendered tolerant to *Y* antigen either by neonatal injection or by repeated injections of male spleen cells when adult, it would seem that an immunological reaction of the kind postulated is not necessary for implantation to occur

Although the numbers raised are not large, it is clear from Table 2 that no striking effect on sex ratio occurs in the young of female mice strongly immunized against *Y* antigen, even in a situation (that is, within a highly inbred strain) where no antigenic differences other than that represented by the *Y* antigen would be expected It therefore seems unlikely, though of course not impossible, that immunization against *Y* antigen plays the part postulated for it by Renkonen *et al* [1] in the antigenically complex situation of a human pregnancy in which the degree of immunization would presumably be weaker In addition, studies on mice[8,9] suggest that repeated pregnancies induce unresponsiveness to *Y* antigen, rather than even weak immunity

The more detailed data published by Renkonen *et al* [10] do not convincingly support an immunological interpretation For initiating and maintaining a state of immunity, boys born recently should prove more effective than those born longer ago Yet it appears from their data that the earlier in the family boys are born, the greater is the depressing effect upon sex ratio Where two boys are followed by two girls, for example, the ratio of boys to girls among fifth children is lower than when two girls are followed by two boys This is the reverse of what an immunological hypothesis would lead one to predict

Red Water and Mass-Mortality of Fish near Cape Town

Red water, caused primarily by a very high concentration of the dinoflagellate *Gonyaulax polygramma* Stein, associated with another dinoflagellate, *Prorocentrum micans* Ehrb , in smaller numbers, appeared in False Bay, near Cape Town, during March and the early part of April 1962 This bloom resulted in a mass-mortality of fish and marine invertebrates, when the dinoflagellates died in large numbers

Red water is a common phenomenon around the coasts of South Africa and has been shown to be caused by a variety of different organisms, including dinoflagellates and ciliates These different organisms appear to be the causes of several distinct phenomena, including mussel poisoning of man and mass mortalities of marine fauna Sapeika[1] has shown that the pharmacological action of the toxin extracted from the local mussels is similar to that isolated from shell-fish in other parts of the world Mass-mortalities of marine fauna are rare around the coasts of South Africa Some early cases were reported by Gilchrist[2] Off the coast of South West Africa, however, complicated periodic mortalities occur as reviewed by Brongersma-Sanders[3], and later studied by Copenhagen[4] Mortalities farther north in Angola waters have been reviewed by Paredes[5]

In the present case the mass-mortality of fish and invertebrates occurred in limited areas only when the red plankton died and decayed in large numbers The death of fish and invertebrates was apparently caused primarily by the depletion of oxygen in the water aggravated by the release of decay products The living *Gonyaulax* up to the time they died do not appear to have produced any harmful effects on other fauna Healthy patches of red water were found to be supersaturated with oxygen during the day

Prof N Sapeika, of the Department of Pharmacology of the University of Cape Town, carried out toxicity tests on fish, limpets (*Patella longicosta*) and black mussels (*Mytilus perna*) we collected from the affected area The mussels in particular would have become poisonous if there had been any toxic organisms present However, an extract prepared from 12 black mussels by the Dack method produced no neurotoxic symptoms or death in six white mice injected with the material Similar negative results were obtained by an independent medical specialist with other experiments

The *Gonyaulax polygramma* population in this area showed considerable morphological variation as described by Taylor[6] Observations on the non-thecate and cyst forms were similar to those of Sousa e Silva[7] in cultures of *G diacantha* (Meun) Schiller In *G polygramma* it also appeared that multiplication occurred in the non-thecate stage This species was found to be strongly luminescent It is normally considered to be a warm-water species with a wide distribution in subtropical waters, and it only became abundant in the warm surface waters of False Bay The organisms in this population were appreciably smaller than is characteristic for the species

Gonyaulax polygramma was found in small numbers in the cold water south-west of Cape Town at the beginning of March There was an influx of this cold, nutrient rich water into False Bay at this time associated with a period of south-east winds In False Bay the surface-temperature rose, and the *Gonyaulax* multiplied rapidly in these favourable conditions A period of two weeks of calms and northerly winds caused the plankton-rich water to accumulate and eventually to die and decay in certain limited areas where the concentration was greatest The smell of decaying plankton and fish was noticeable in Cape Town 30 miles away After a few days a change of wind direction dispersed the decaying plankton Being largely a surface phenomenon wind was a primary factor in its distribution A further period of calms resulted in a recurrence of the mass decay of plankton and another though smaller mortality of fish two weeks later This case shows a remarkable similarity to mortalities due to *Gonyaulax polyedra* Stein on the coast of California and described by Kofoid[8] and others The only previous recorded case of a mortality due to *G polygramma* was in Japan, where pearl-oyster beds were affected[9]

MICROBIOLOGY

Electrophoresis of Colicines in Agar Gel

In 1953 Ludford and Lederer[1] described the electrophoresis of colicines in agar gel, using a simple apparatus deriving its potential from a battery. Experiments were carried out in this department in 1959 using an apparatus similar to that used by Ludford and Lederer. The results were sufficiently encouraging to suggest that the method, suitably modified, could provide information regarding the colicine complexes and might possibly be of use for the differentiation of strains of colicinogenic bacteria. The description and use of the apparatus finally evolved will be described elsewhere. Briefly the method is as follows; a colicine-producing organism was grown as a spot inoculum in the centre of a strip of nutrient agar. The organisms were killed with chloroform, and a potential applied across the strip. The presence of colicine was revealed by areas of inhibition in a carpet of a sensitive indicator organism afterwards grown on the surface of the agar.

Fig. 1 shows the type of picture obtained. This is a photograph of Fredericq's colicines *A* to *I* [2] and shows the variety of inhibitory patterns that can be produced by different colicines acting on the same sensitive indicator organism. Experiment has shown that these patterns are reproducible although, as mentioned later, it is possible to produce variations in the picture.

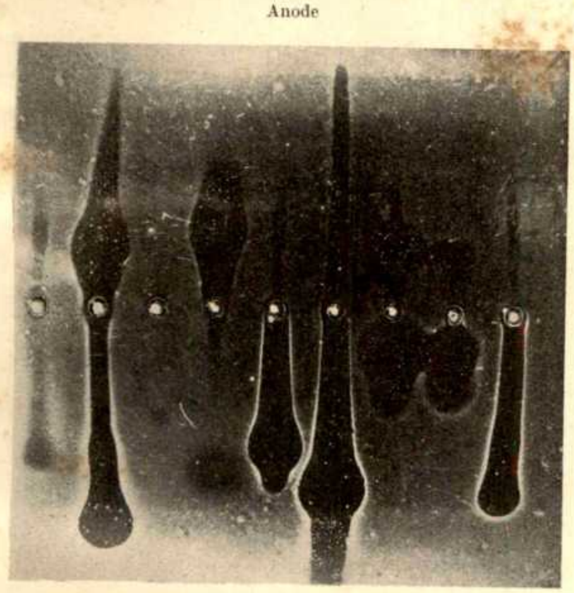

Fig. 1. Electrophoresis of Fredericq's colicines *A*, *B*, *C*, *D*, *E*, *F*, *G*, *H* and *I*, respectively, reading from left to right with the anode end uppermost. Medium was nutrient agar (*p*H 7·4) prepared in this department

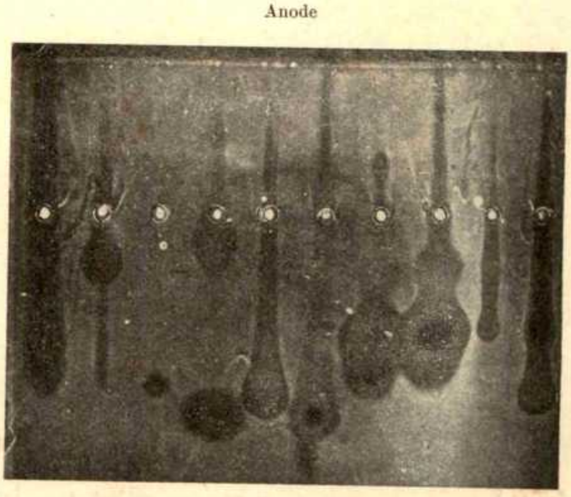

Fig. 2. Electrophoresis of Fredericq's colicines *A*, *B*, *C*, *D*, *E*, *F*, *G*, *H*, *I* and *J* read as in Fig. 1. Medium was nutrient agar (*p*H 7·4) prepared from 'Difco' nutrient broth

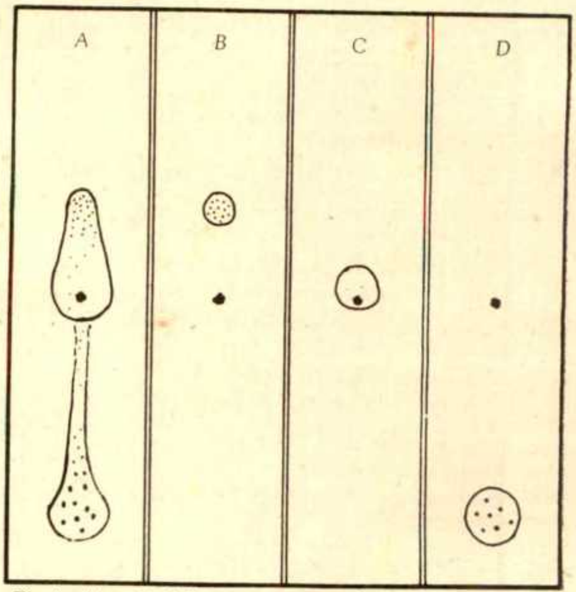

Fig. 3. Theoretical diagram of the breakdown of a colicine complex by the use of several different sensitive indicator organisms, based upon several experiments with different colicine complexes. *A*, Most sensitive indicator available; *B*, *C* and *D*, indicators of differing sensitivity

One fact which is immediately obvious is that there is a large amount of tailing and streaking of the inhibition zones, and in some cases it is difficult to see where one component of the colicine complex begins and where it ends. This tailing and streaking of the zones is due to the type of electrophoresis (frontal) and electro-endosmosis[3]. It was found possible to characterize strains of *E. coli* and *Shigella sonnei* not only by their ability to produce colicine but also by the appearance of the colicine pattern on the electrophoresis plate. Abbott and Shannon[4] and Shannon[5] devised a method for typing *Sh. sonnei* and *E. coli* 0·55: *B*5 respectively, by the patterns of inhibition their colicines produced in a selected group of sensitive indicator organisms. This method is in use in several public health laboratories in Great Britain including the Dysentery Reference Laboratory at Colindale. Strains of *Sh. sonnei* which had been typed by the Abbott and Shannon technique at Colindale were sent to this department, where their colicines were subjected to electrophoresis. There was complete agreement between the two methods where strains from the same outbreak were concerned. However, it is too early to say that the agreement is 100 per cent where strains from separate outbreaks were involved.

The electrophoretic patterns have never varied when the conditions of electrophoresis have remained the same, whereas variation does, sometimes, occur in the inhibition spectrum revealed by the sensitive strains used in the Abbott and Shannon technique. However, variation can occur in the electrophoretic pattern, and this can be caused by changes in the agar medium. In this case the zones sometimes take on a different appearance and may change their direction of movement (Figs. 1 and 2).

That there are several colicines produced by the same organism has been shown by electrophoresis using several different sensitive indicator organisms on the same plate. Fig. 3 is a diagram to illustrate this finding.

These few experiments suggest that the method is worthy of attention, and work is continuing in this Deparment with the view of obtaining a better understanding of the factors controlling the electrophoresis patterns of colicines and also to evaluate the technique for the characterization of colicinogenic bacteria.

Production of Yeast Protoplasts by an Enzyme Preparation of *Streptomyces* sp.

Eddy and Williamson[1] obtained structures resembling intact protoplasts from cells of *Saccharomyces* after digestion of the cell-wall by enzymes from the gut of the snail *Helix pomatia*. This report was followed by a number of papers on the structural and physiological properties of the yeast protoplasts obtained by this procedure[2–5].

One cannot expect to find a lytic preparation from any organism able to produce protoplasts from all micro-organisms. Accordingly, it is of considerable interest to obtain preparations from different sources which have a chance of different, though perhaps partially overlapping, characteristics. We are now examining the possibilities of the *Streptomyces* and snail enzymes ; and will eventually examine a mixture of both for the preparation of protoplasts from representatives of other types of micro-organisms.

We have found a species of *Streptomyces* which produces an enzyme able to lyse cell-walls of a number of yeast species and also renders possible the preparation of protoplasts. The *Streptomyces* was isolated by us from the soil, using the plate method with the cell-wall agar media described by Salton[6].

In our investigations, instead of the snail enzyme, we used a lytic preparation produced in the growth media by this *Streptomyces*. The enzyme preparation was obtained after 60 per cent ammonium sulphate precipitation and redissolution in a small volume of distilled water followed by dialysis against distilled water. This preparation was very stable and able to digest isolated cell-walls of *Saccharomyces fragilis*, *Candida utilis*, *S. rossei*, *S. cerevisiae PM*-1 and *SM*-100, *Kloeckera apiculata* and *Torula utilis*, named in decreasing order of susceptibility. A strain of *Torulopsis aedis* has been found to be very resistant to lysis.

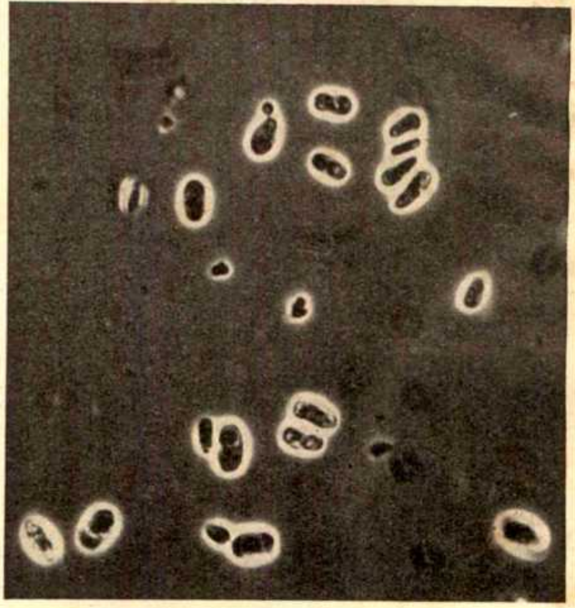

Fig. 1. Young cells of *Candida utilis*. (Phase contrast)

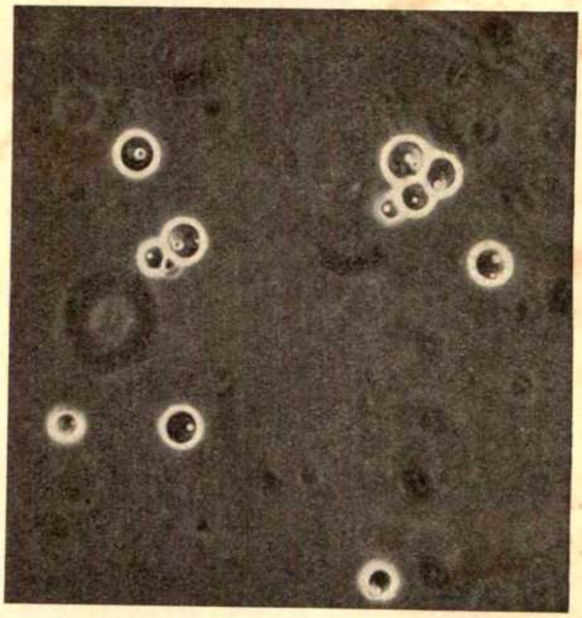

Fig. 2. Isolated protoplasts of *Candida utilis*. (Phase contrast)

Using susceptible species of yeasts, it is observed that it is much easier to obtain protoplasts with young growing cultures. Young cells of each of the aforementioned yeast species were obtained by inoculating a small volume of a 24–28-h old culture into a liquid medium. The initial medium consisted of glucose 2 per cent (w/v) and yeast extract 0·3 per cent (w/v). After a growth period of 18 h at 28° C under vigorous aeration, 20 ml. of this culture were transferred into 80 ml. of the same fresh medium. The cells were collected by centrifugation after about 5 h when a population density of about 5×10^6 cells per ml. was attained. The cells were thoroughly washed in distilled water and were resuspended at a density of about 10^6 cells per ml. in 0·1 M phosphate buffer *p*H 6·8 containing 0·8 M mannitol.

For conversion of the yeast cells to protoplasts, a solution of the enzyme containing 10 mg per ml. was added. The quantities of the enzyme preparation used ranged between 0·2 and 0·5 ml. of dilute solution per ml. of incubation mixture. The digestion of the cell-wall was allowed to take place at 30° C for variable periods of time with gentle agitation. After 2–4 h incubation, the protoplasts began to emerge from some of the yeast cells in the more susceptible species, although protoplast formation was usually complete in 6 or 7 h. The yield of protoplasts, when *Candida utilis* was used, was about 90 per cent. The protoplasts, observed under the phase microscope to contain vacuoles, appeared to be as dense as the contents of the cells from which they came. After the extrusion of the protoplasts a few empty cell-walls could be seen. It is not yet known whether the remaining envelope surrounding the cytoplasmic content is a true protoplast membrane[7] since immunochemical tests relating to wall material in the yeast species used are not yet available nor is the chemistry of the wall material properly known.

The free protoplasts are sensitive to osmotic shock; and lysis was immediately observed under the microscope when they are placed in distilled water. The protoplasts are very stable when stored in hypertonic solution in the cold room for several days. The lytic system is very active on yeasts and fungi, and showed no activity against a number of species of bacteria.

Extensive investigations have been made on the lytic properties of the isolated enzyme[8].

Protoplasts of the Giant Bacterium, *Caryophanon latum* Peshkoff

CONTRARY to current information, Provost and Doetsch[1] reported recently that *Caryophanon latum* Peshkoff is a Gram-positive bacterium. Evidence cited for this contention, in addition to staining, included susceptibility to egg-white lysozyme and formation of 'protoplasts'. The results of the investigation reported here indicate that protoplasts are formed when osmotically buffered suspensions of *C. latum* are exposed to egg-white lysozyme, and that these bodies possess many characteristics common to protoplasts of other Gram-positive bacteria.

C. latum 1·8 was used in all experiments and criteria suggested by Brenner *et al.*[2] were applied, where possible, in determining that the spherical structures were, in fact, protoplasts.

Surface cultures of *C. latum* were grown on a medium of 1·0 per cent (w/v) 'Hy-case *SF*' (Sheffield Chemical Co., Norwich, New York), 0·5 per cent (w/v) 'Bacto-Yeast Extract' (Difco Laboratories, Detroit, Michigan), 0·5 per cent anhydrous sodium acetate, 1·5 per cent agar (*p*H 7·8), and incubated for 18 hr. at 25° C. Growth was gathered in sterile distilled water, washed twice, and resuspended in diluents the composition of which depended on the nature of the experiment to be undertaken.

When treated with 20 μgm./ml. lysozyme, cell suspensions in 0·05 *M* sodium chloride rapidly decreased in optical density as contrasted to those in a medium of 0·3 *M* sucrose, 0·016 *M* magnesium chloride, and 0·03 *M* phosphate buffer, *p*H 6·7 (Fig. 1). Maximum turbidity reduction occurred

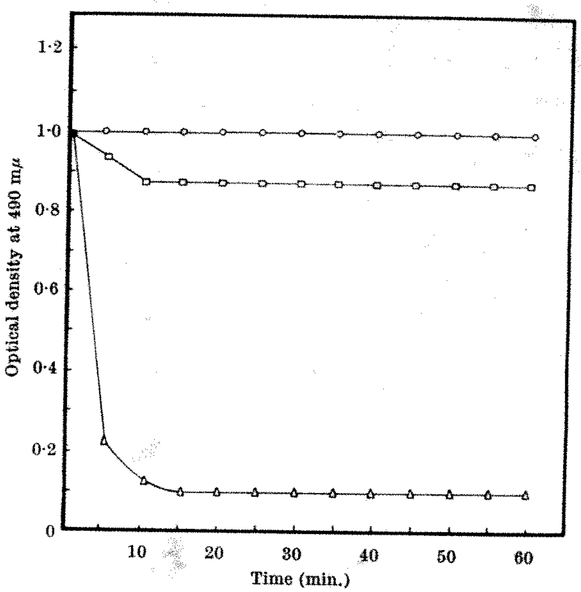

Fig. 1. Effect of lysozyme (20 μgm./ml.) on optical densities of *C. latum* suspensions. ○, Untreated controls; □, cells suspended in 0·3 *M* sucrose, 0·016 *M* magnesium chloride, 0·03 *M* phosphate buffer, *p*H 6·7; △, cells suspended in 0·05 *M* sodium chloride, *p*H 6·7

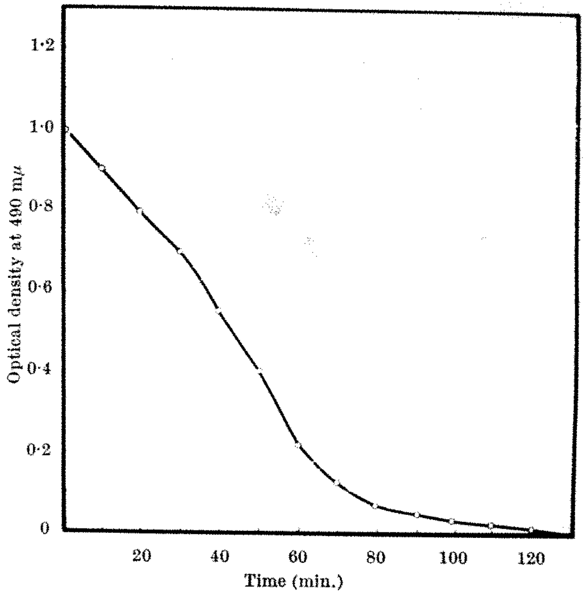

Fig. 2. Effect of lysozyme (20 μgm./ml.) on optical density of *C. latum* cell walls in 0·067 *M* phosphate buffer, *p*H 6·7

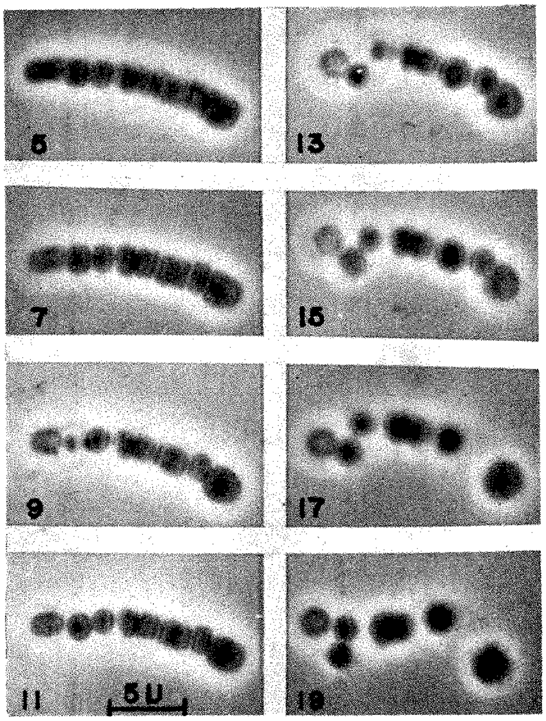

Fig. 3. Bright-phase photomicrographs of *C. latum* being converted to protoplasts upon dissolution of cell walls by lysozyme (20 μgm./ml.). The numbers denote time (min.) elapsed after addition of lysozyme

within 15 min. after addition of lysozyme. Bright phase-contrast microscopic examination of buffered-sucrose suspensions revealed spherical, phase-dense protoplasts and intact trichomes were not observed in such suspensions. Purified cell wall preparations of *C. latum* suspended in 0·067 *M* phosphate buffer (*p*H 6·7) containing 20 μgm./ml. of lysozyme were completely dissolved (Fig. 2) when determined turbidimetrically.

The production of protoplasts by *C. latum* was followed easily using phase-contrast microscopy. Immediately after addition of lysozyme to a bacterial suspension, 1 loopful of the mixture was transferred to a slide, covered with a cover-glass, and sealed with melted 'Petrolatum'. Fig. 3 shows numerous protoplasts emerging from a single trichome. The number of protoplasts derived from individual trichomes varied, and depended on the length and number of cellular units present therein. Fig. 3 clearly depicts the emergence of 7 distinct protoplasts, 1 of which lysed prior to completion of cell-wall lysis. There was definitely a greater number of protoplasts released per trichome from young cultures (14–18 hr.), and older cultures (24–30 hr.) did not possess as many septa per trichome. Not all protoplasts derived from a trichome existed as single spherical bodies. This can be observed in the last photograph in Fig. 3. Continued microscopic observations of such bodies showed them to remain paired. This was interpreted to mean that in many cases cytoplasmic membranes were completely laid down, but that the cross-walls were not. The presence of single protoplasmic membranes where secondary walls were only partially completed was shown by the resulting formation of only 1 protoplast from such structures. Dissolution of *C. latum* trichomes by lysozyme and resultant formation of protoplasts supply additional evidence for the multicellular structure of this organism as envisaged by Pringsheim and Robinow[3].

This work was supported in part by a training grant (*2G*-615) provided by the Division of General Medical Sciences, National Institutes of Health, Bethesda, Md. We thank W. L. Wallenstein for help in the preparation of the figures.

Lack of Pectic Enzyme Production by Non-Pathogenic Species of *Verticillium*

THE presence of enzymes belonging to the pectic group of enzymes has been demonstrated in a large variety of plant pathogenic organisms. The existence of such hydrolytic enzymes has been shown in culture filtrates of many pathogenic moulds, the enzymes being isolated from those filtrates and their toxic effect on plants demonstrated[1]. A degradation of the pectic material of the cell wall, principal site of attack of these enzymes, could bring about wilting. It thus appears that the formation of pectic enzymes may play an important part in producing the wilting symptoms of many plant diseases.

As a part of the investigations on the lytic activity of a non-pathogenic strain of *Verticillium hemileiae* on uredospores of various rust[2], several species of *Verticillium* have been tested for ability to produce pectic enzymes *in vitro*. Pectolytic activity in fungi has generally been found to depend on a complex of enzymes which may include pectin-methyl-esterase, polygalacturonase and depolymerase enzymes. Forty strains of the following species of *Verticillium* were used in this study: *V. albo-atrum*, *V. tricorpus*, *V. dahliae*, *V. nigrescens*, *V. lateritium*, and *V. hemileiae*, some isolated by us and others received from the Estaçao Agronomica Nacional of Oeiras (Portugal), the University College of Swansea and the Oregon State University. The fungi were grown on a pectin medium[3] for 20 days under static conditions at 28°. Pectolytic activities in the *Verticillium* cultures were determined using the methods described by Waggoner and Dimond[4], and that of the ethanol precipitation[3].

Very high pectolytic activity was found with all the pathogenic species of *Verticillium* whereas no activity was detected in the non-pathogenic strains. No effect was found in the production of pectic enzymes when the substrate was changed. The occurrence of pectic enzymes in all the pathogenic species of *Verticillium* studied was more or less expected and more striking was the lack of pectolytic activity in the non-pathogenic strains tested. These observations might suggest that *Verticillium*, which produce enzyme preparations showing pectolytic activity, are plant pathogens. Smith[3] has found that production of pectin-methyl-esterase enzyme is confined to a small number of pathogenic bacteria. Additional proofs of the role of the pectic enzymes in pathogenesis have also been demonstrated by other workers[4,5].

CYTOLOGY

Sex Chromatin in Adult and Fœtal Rat

In 1953, Moore and Barr[1] published the results of an investigation of the occurrence of sex chromatin in neurons from different mammalian species. These authors were unable to show any sex chromatin in rat. However, three years later de Castro *et al.*[2] found typical such in ameloblastic nuclei from young rats aged one day; and in 1959, Wolf-Heidegger and Klinger[3] described sex chromatin in, among other tissues, spinal ganglion cells from adult rats as well as from fœtuses aged 13 and 16 days. Hinrichsen and Gothe[4] and Feiner[5] found a difference in the chromatin distribution between male and female rats. The last-mentioned author, however, found this difference concerning spinal ganglion cell nuclei only in fœtuses and not in adults. In trophoblastic nuclei from rat embryos, Zybina[6] discovered sex chromatin after 6 days.

The rats used by us in our investigation were of the Sprague–Dawley strain. The material was taken from 3 adult males and 4 adult females, 3 male and 3 female fœtuses aged 16 days post-coitum and 12 male and 13 female fœtuses aged 14 days post-coitum. Finally, 30 fœtuses aged 13 days and 41 fœtuses aged 12 days post-coitum were investigated. In the two last-mentioned groups no certain gonad differentiation could be established. Only spinal ganglions were investigated. From adult animals 3–4 ganglia were dissected out, after which these, as well as most of the fœtal material, were fixed in Bouin's fluid. Some fœtuses were fixed in Davidson's fluid. Neither of the fixing fluids, however, proved better than the other in this connexion. Staining in all instances was made in gallocyanin-chrom-alum according to Einarson[7] after previous treatment in 10 per cent perchloric acid for 12 h at + 4° C. 500 ganglion cell nuclei from each of the adults as well as from fœtuses aged 16 days were studied, and 200 or 300 from each of the remaining fœtuses. In the present investigation the occurrence of solely marginally sex chromatin was examined, that is, about 1μ large triangular or plane-convex body situated along the nucleic membrane. During the examination of the ganglion cell nuclei the number of nuclei showing marginally sex chromatin according to the aforementioned definition was determined.

The results from the investigation appear in Table 1, where the average number of nuclei showing marginally sex chromatin in the different stages is given in percentage of the total number of nuclei examined.

Table 1

	Female (per cent)	Male (per cent)
Adult	39·9	3·6
16 days post-coitum	48·4	8·7
14 days ,,	50·9	8·8
13 days ,,	50·2	9·9
12 days	50·4	9·3

Concerning adults and fœtuses aged 16 and 14 days, the nuclear sex identified with the help of marginally sex chromatin in all instances agreed with the gonadal sex of the specimen. In the fœtal groups aged 12 and 13 days it was not always possible to decide definitely the sex of the specimen histologically because testes with delayed differentiation could be misinterpreted as ovaries. In these groups, however, a grouping of marginally sex chromatin around the averages 50·4 and 9·3 per cent (12 days) and 50·2 and 9·9 per cent (13 days) was obtained. Sex identification with the help of marginally sex chromatin in non-gonad differentiated fœtuses agreed in all instances with the results from sex identification obtained by gonad volume determination[8]. No significant difference exists between the averages for marginally sex chromatin in males of different fœtal ages or in females of different fœtal ages. On the other hand, the difference between the averages for adults and fœtuses is significant for males as well as females (male: $\chi^2 = 55{\cdot}86$ for 1 *D.F.*, $P < 0{\cdot}001$; female: $\chi^2 = 70{\cdot}01$ for 1 *D.F.*, $P < 0{\cdot}001$).

Cytological Investigation of Triploid Sterility

The problem of high sterility in triploids is well known since it is easily observed in practice. Most explanations of the cause have been genetical but a cytological follow-up often lends weighty support. So far cytological observations have shown that in triploids the extra (n) chromosome complement per pollen mother cell is shared between the two daughter nuclei at anaphase I in various proportions over and above the division of the basic diploid chromosome number. The movement of the chromosomes is at random so that when the daughter nuclei separate after anaphase II the pollen grains are produced with approximately binomial frequency distribution of the chromosome classes ranging from n to $2n$ chromosomes.

This has been investigated in maize, solanum, *Narcissus*, *Petunia* and tomatoes, and the results thus obtained only give the impression that the formation of a fertile triploid depends on the fusion between pollen and ovule of complementary chromosome numbers, that is, n to $2n$ or $n + 1$ to $2n - 1$, etc. It is true that the chances of such complementary chromosome numbers meeting are not terribly high, but they cannot alone account for the scale of sterility observed in practice.

One way of looking for the answer to the problem lies in observations on the particular chromosomes which make up the chromosomes in the pollen grains and the ovules. But there are very few suitable species in which all the individual chromosomes can be distinguished, such as *Crepis*, maize and *Drosophila*.

I have examined the chromosomes of the bluebell, *Endymion nonscriptus* (L) Garcke, and have succeeded in identifying all of them[1]. This has made it possible to carry out the sort of studies in question[2].

68 pollen grains were examined at pollen mitosis[1] and all the chromosomes in each such grain were identified.

One of the facts which emerged from this investigation was that some of the pollen grains were not pure but either contained all 3 of a particular chromosome (triplicates), or have missing all 3 of a particular chromosome (incomplete grains). The triplicates were more numerous than the complementary incomplete grains and this seems to support the genetical idea that duplications are not as deleterious as deletions. The satellitic chromosome was found to be always present in each pollen grain at least once, which may mean that the absence of this particular chromosome would otherwise be deleterious to the grain.

The presence of impure grains (that is, triplicates and incomplete grains) obviously decreases considerably the chances of proper fertilization since these can lead to the formation of tetrasomic or nullisomic triploids none of which was found among the triploids studied. This cytological analysis provides a more convincing explanation of the scale of sterility found in triploids than has been given by genetical evidence.

AGRICULTURE

Measurement of Evapo-Transpiration from Large Tanks of Soil

THE direct measurement of evapo-transpiration on any sufficiently large scale requires very expensive equipment. In an attempt to find a cheaper method we have been experimenting with semi-enclosed hydraulic systems involving the use of water-filled, flexible bags on which large tanks can be readily supported (Fig. 1). The change in height of the balancing column of water measures changes in pressure on the system.

It is well known that the factors which determine the volume of water in the system and the height of the balancing column of liquid are pressure and temperature. Since pressure is equal on both sides of the balanced system, no complications arise due to changes in environmental atmospheric pressure; however, changes in temperature, by causing changes in volume of the liquid, affect readings of the water column. In our experiments the flotation bags will be used at depths of soil below 4 ft., where there is little diurnal or even annual change in temperature to affect a system of high specific heat. For example, we have floated a steel tank 8 ft. long by 4 ft. wide and 4 ft. deep, filled with water, and supported on three interconnected water-filled rubber bolsters, each some 9 ft. long and 18 in. wide (Fig. 1).

Evaporation from this tank was compared with evaporation from a series of evaporation pans in use at this station. The results are shown in Fig. 2, which illustrates the cumulative records over a sample 12-day period.

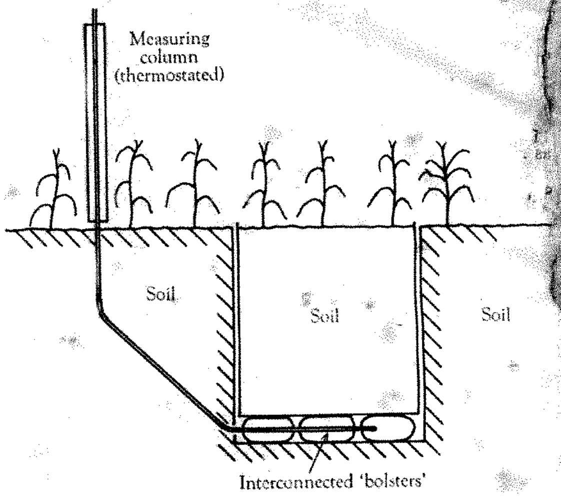

Fig. 1

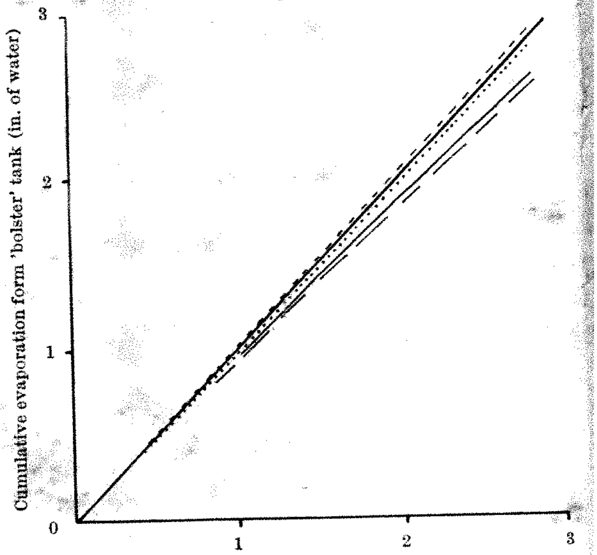

Fig. 2. Cumulative evaporation from Trumble tank (– – –), sunken pan (· · · ·), class *A* pan (—— —— ——) and raised gridded tank (———). Closeness of agreement between the 'bolster' tank and any of the evaporation pans is shown by the nearness of the lines to the thick continuous line at 45° to the axes

Whereas evaporation on rain-free days from all these devices is of the same order, our tank gives results which are more closely correlated on a daily basis ($r = 0{\cdot}995$) with the Trumble tank and sunken pan than with the remainder. The Trumble tank is a water-insulated tank some 35 in. deep, while the sunken pan is air insulated and only 17 in. deep.

The experimental tank has now been filled with soil in place of the water, and the bolsters continue to support it and show changes which are believed to be due to loss in evaporation from the soil surface, since additional amounts of water appear to be accurately reflected by changes in height of the measuring column.

Further tests are to be carried out on a larger scale to study both potential and actual evapo-transpiration under a variety of local crops.

FORTHCOMING EVENTS

*(Meetings marked with an asterisk * are open to the public)*

Monday, October 1

Society of Engineers (at the Geological Society, Burlington House, ccadilly, London, W 1), at 5 30 p m —Mr A J Davenport "Plastics a Structural Material"

Society of Chemical Industry, London Section (at 14 Belgrave Square, London, S W 1), at 6 30 p m —Scientific Films

Monday, October 1—Tuesday, October 2

Plant Phenolics Group and the British Mycological Society (at the School of Pharmacy, Brunswick Square, London, W C 1), at 10 a m daily—Symposium on "Fungi and their Metabolites"

Monday, October 1—Wednesday, October 3

British Society of Rheology (at the Hotel St George, Harrogate) —Symposium on "The Rheology of Emulsion"

Tuesday, October 2

Institution of Chemical Engineers, South-Eastern Branch (at the Geological Society, Burlington House, Piccadilly, London, W 1), at 6 p m —Mr M Ruhemann 'Frontiers of Technology—Low Temperature"

Institution of Mechanical Engineers, Internal Combustion Engines Group (at 1 Birdcage Walk, Westminster, London, S W 1), at 6 p m —Discussion on "Rocket Motors"

Tuesday, October 2—Thursday, October 4

Aslib (at Norbreck Hydro, Blackpool)—36th Annual Conference

Wednesday, October 3

Colour Group (Great Britain) (in Lecture Theatre No 2 of the new Physics Department, Imperial College, London, S W 7), at 3 10 p m —Dr R A Weale "The Duplicity Theory of Vision", 4 p m —Dr P H Silver "The Spectral Sensitivity of Animals"

Royal Society of Medicine, History of Medicine Section (at 1 Wimpole Street, London, W 1), at 5 15 p m —Prof J Needham "China and the Origin of Medical Examinations"

British Institution of Radio Engineers, Radar Group (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W C 1), at 6 p m —Mr G G Roberts "Storm Warning and Wind Finding Radar"

Thursday, October 4

Society of Chemical Industry, Agriculture Group (at 14 Belgrave Square, London, S W 1), at 11 a m —Meeting on "Toxic Products in Groundnuts"

Institution of Mechanical Engineers, Internal Combustion Engines Group (at the James Watt Memorial Institute, Great Charles Street, Birmingham), at 6 p m —Mr S H Henshall "The Turbocharged Loop Scavenge Diesel Engine"

Institution of Mechanical Engineers, Nuclear Energy Group (at 1 Birdcage Walk, Westminster, London, S W 1), at 6 p m —Discussion on "The Basis of Temperature Limitations"

Society of Instrument Technology (at the Royal Institution, 21 Albemarle Street, London, W 1), at 6 p m —Sir Harry Melville, F R S "The Effect of Instrumental Development on the Progress of Chemistry" (Second Thomson Lecture)

Institute of Metals (at 17 Belgrave Square, London, S W 1), at 7 p m —Mr W K B Marshall "The New Welders" (Chairman's Address)

Thursday, October 4—Friday, October 5

Cement and Concrete Association (at Church House, Great Smith Street, London, S W 1), at 10 a m on Thursday and 9 30 a m on Friday —Conference on "Housing from the Factory"

Thursday, October 4—Saturday, October 6

Council for the Preservation of Rural England (at Lowestoft, Suffolk)—Twenty-third National Conference—"Post-War Developments in the Countryside"

Friday, October 5

Biochemical Society (at the Royal College of Surgeons, Lincoln's Inn Fields, London, W C 2), at 10 a m —Colloquium on "Radioautography" (Chairman, Mr A J Hale), and original communications

Institute of Metal Finishing (at Quaglino's, Bury Street, St James's, London, S W 1), at 2 30 p m —Annual General Meeting 3 30 p m —Dr T P Hoar "On the Electrochemistry of Nickel" (Hothersall Memorial Lecture)

Society of Chemical Industry, Fine Chemicals Group (at 14 Belgrave Square, London, S W 1), at 6 30 p m —Prof J H Turnbull "Enzymes, Drugs and Antibodies, some Chemical Common Factors"

Saturday, October 6

Nutrition Society (at the Medical School, Guy's Hospital, London, S E 1), at 10 30 a m —Symposium on "Fluoridation"

Monday, October 8

Plastics Institute, Reinforced Plastics Group (at the Wellcome Building, Euston Road, London, N W 1), at 4 p m —Symposium on "Design Considerations in Three Different Fields"

Institute of Biology (at the French Institute, Queensberry Place, London, S W 7), at 5 15 p m —Prof F Morel (French Centre for Nuclear Studies, Saclay) "Some Aspects of Kidney Function as Revealed by Tracer Studies" (Third Louis Rapkine Memorial Lecture)

British Society for the Philosophy of Science (in the Joint Staff Common Room, University College, Gower Street, London, W C 1), at 5 30 p m —Mr J R Lucas "The One Concept of Probability"

Institution of Mechanical Engineers, Applied Mechanics Group (at 1 Birdcage Walk, Westminster, London, S W 1), at 6 p m Discussion on "Testing Machines"

Royal Institute of Chemistry, London Section (joint meeting with the Ewell County Technical College Chemical Society, at the Ewell County Technical College, Reigate Road, Ewell), at 7 p m — Dr. H J Cluley "Complexometric Analysis"

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned

Computing Assistant (with a good honours degree in mathematics or in a pure or applied science) in the Electronic Computing Laboratory—The Registrar, The University, Leeds, 2 (October 6)

Principal Scientific Officer or Senior Scientific Officer (honours graduate in animal husbandry or in another appropriate science, with considerable research experience) to work as the senior member of a team undertaking research into the nutrition of hill sheep and associated problems—The Secretary, Hill Farming Research Organization, 48 Palmerston Place, Edinburgh, 12 (October 6)

Scientific Officers (2) (with a good honours degree in chemistry (physical, inorganic or organic) or in biochemistry, and preferably some postgraduate experience) at the National Research Station, Wellesbourne, in the following Sections (1) Chemistry to study plant nutrients in soils and their effects on the growth of vegetable crops, (2) Weeds to work on problems associated with the absorption, movement and persistence of residual herbicides in soils—The Secretary, National Vegetable Research Station, Wellesbourne, Warwick (October 6)

Lecturer (preferably with special qualifications in symbolic logic) in Philosophy at Victoria University of Wellington, New Zealand—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S W 1 (New Zealand and London, October 8)

Lecturer (with a good honours and preferably a higher degree, and a special interest in structural geology, mineralogy and petrology) in Geology—The Secretary, Sir John Cass College, Jewry Street, London, E C 3 (October 10)

Assistant Lecturer, Grade B (with a good honours degree in mathematics of a British university, and prepared to lecture in mathematics to the level of first year degree or Diploma in Technology in engineering and science) in Mathematics—The Clerk to the Governors, Woolwich Polytechnic, London, S E 18 (October 12)

Computing Assistant (preferably with a knowledge of physics and mathematics to degree level) to assist in measurement and analysis of results obtained in optical maser experiments—The Principal, Royal Holloway College (University of London), Englefield Green, Surrey (October 12)

Departmental Graduate Assistant (with a degree in physics or electrical engineering, or a comparable qualification, and special training in electronics) in the Department of Chemistry, to help in the design and construction of electronic equipment to be used in gamma-ray spectrometry as applied to an investigation of the Mossbauer Effect—The Registrar, King's College (University of Durham), Newcastle upon Tyne, 1 (October 12)

Research Assistant (preferably with a good honours degree in engineering or physics, and preferably some experience in automatic control) in the Department of Mechanical and Marine Engineering for duties which will include research on control systems—The Registrar and Secretary, King's College (University of Durham), Newcastle upon Tyne, 1 (October 12)

Lecturer or Demonstrator in Chemical Pathology—The Registrar, The University, Leeds, 2 (October 13)

Lecturer (preferably with a degree in mathematics or science, a professional qualification in education and some teaching experience in schools) in Education—The Secretary, The Queen's University, Belfast, N Ireland (October 13)

Lecturer in Applied and Industrial Microbiology in the Department of Chemical Engineering—The Secretary, University College, Gower Street, London, W C 1 (October 15)

Lecturer in Education at Rhodes University, Grahamstown, South Africa—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S W 1 (South Africa and London, October 15)

Reyrolle Student in Electrical Power Engineering—The Registrar and Secretary, King's College (University of Durham), Newcastle upon Tyne (October 15)

Senior Lecturer in Geology (Petrology) at the University of Natal, Durban South Africa—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S W 1 (South Africa and London, October 15)

Manchester Royal Botanical Society Lecturer in Horticulture—The Registrar, The University, Manchester 13 (October 19)

Official Fellow and Tutor in Mathematics—The President, Magdalen College, Oxford (October 22)

Lecturer in Genetics in the Departments of Botany and Zoology in the Faculty of Science—The Registrar, The University, Manchester, 13 (October 26)

LECTURER (with a wide interest in the subject so as to be able to lecture to students of both departments) IN GENETICS IN THE DEPARTMENTS OF BOTANY AND ZOOLOGY IN THE FACULTY OF SCIENCE—The Registrar, The University, Manchester, 13 (October 26)

READER (with a Ph D in physics or a research record of equivalent level, and preferably teaching experience, or experience in leading research workers) IN PHYSICS at the University of Queensland, Brisbane—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S W 1 (Brisbane and London, October 27)

SECOND CHAIR IN EDUCATION (qualifications in educational psychology or experimental techniques in education desirable but not essential)—The Secretary and Registrar, The University, Southampton (October 27)

LECTURER (preferably with qualifications in clinical and abnormal psychology) IN PSYCHOLOGY at the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London S W 1 (Australia and London, October 29)

LECTURER (with appropriate qualifications in experimental psychology or physiology and preferably research experience in a relevant field) IN THE DEPARTMENT OF PSYCHOLOGY—The Secretary, Institute of Neurology, The National Hospital, Queen Square, London, W C 1 (October 30)

LECTURER or ASSISTANT LECTURER IN MEDICINE, LECTURERS (2) IN SURGERY, and a LECTURER or ASSISTANT LECTURER IN BIOCHEMISTRY at the University of Singapore—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Sauare, London, W C 1 (October 31)

LECTURER or ASSISTANT LECTURER (preferably with a special interest or experience in automatic control or in dynamics) IN MECHANICAL ENGINEERING—The Registrar, The University, Leeds, 2 (October 31)

LECTURER or ASSISTANT LECTURER (medically or non-medically or veterinary qualified candidate) IN THE DEPARTMENT OF HISTOLOGY—The Registrar, The University, Liverpool, quoting Ref CV/179 (November 17)

LECTURER IN PURE MATHEMATICS at Monash University, Melbourne, Australia—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S W 1 (Australia and London, November 19)

ACAROLOGIST (with a science degree) at the National History Museum, Adelaide, South Australia, for the care and control of collections of acarina and original research thereon, and routine activities relative to other arachnida—The Agent-General for South Australia, Strand, London, W C 2

ASSISTANT EXPERIMENTAL OFFICER (preferably aged over 22, with a pass degree in physics or an equivalent qualification) for measurement of physical properties of food stuffs—The Secretary, Low Temperature Research Station, Agricultural Research Council, Downing Street, Cambridge

BIOCHEMIST (graduate), for research on gastric proteinases in man—Mr J G Murray, Department of Surgery, King's College Hospital Medical School, Denmark Hill, London, S E 5

BIOCHEMIST (non-medical) for the Group Laboratory, Guildford—The Hospital Secretary, St Luke's Hospital, Guildford, Surrey

BIOLOGIST, to participate in radiopathological research—The Director, Experimental Radiopathology Research Unit Hammersmith Hospital, Ducane Road, London, W 12

HEAD OF THE MATHEMATICAL DEPARTMENT—The Rector, Glasgow Academy, Glasgow, W 2

ELECTRONIC ENGINEER (with experience of constructional and measurement techniques in the UHF band), to assist development of interesting new scientific apparatus for fundamental research—Prof A Charlesby, Royal Military College of Science, Shrivenham, Swindon, Wilts

LABORATORY TECHNICIAN (with two passes in an experimental scientific subject at advanced level G C E or Associateship of I M L T, or equivalent qualifications) to assist in biochemical research on the biosynthesis of proteins—Dr P N Campbell, Courtauld Institute of Biochemistry, The Middlesex Hospital Medical School, London W 1

LECTURER OR ASSISTANT LECTURER IN PHYSICS at the Royal University of Malta—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W C 1

POSTDOCTORAL BIOCHEMIST or CHEMIST, to work with a group on the kinetics and mechanism of action of proteolytic enzymes—Dr D T Elmore, Queen's University, Belfast, N Ireland

RESEARCH ASSISTANT (honours graduate in physics, preferably with some initial knowledge of electronic circuits), to take part in investigations of cosmic rays, using counting techniques for high energy particles—Head of the Department of Physics, Northern Polytechnic, Holloway Road, London, N 7

RESEARCH BURSARY or a RESEARCH ASSISTANTSHIP IN THE CHEMISTRY DEPARTMENT, for work on diffusion and sorption of vapours in polymer films—Dr J A Barrie, Chemistry Department, Imperial College of Science and Technology, London, S W 7

TECHNICAL ASSISTANT (preferably with a knowledge of photography), for research work in the Department of Electron-microscopy at Maida Vale Hospital—The Secretary, Institute of Neurology, The National Hospital, Queen Square, London, W C 1

TECHNICIAN at Pollards Wood Research Station, Chalfont St Giles Bucks, for work on tissue culture—The Secretary, Institute of Cancer Research—Royal Cancer Hospital, 34 Sumner Place, London, S W 7, quoting Ref 301/B/111

ENDECOTTS

TEST SIEVE SHAKER

The unique mechanical action ensures efficient particle sieving
- The circular action travels in a clockwise direction, so that the material passes over the sieve apertures
- Simultaneously a vertical movement clears the apertures
- Will carry up to 8 full depth sieves or 19 half depth sieves

An optional extra is an independent time switch, which can be set between 0 — 60 minutes

SPEEDY—SILENT—ACCURATE CONSISTENT—EFFICIENT

UNIVERSITY OF MANCHESTER

Applications are invited for the post of Manchester Royal Botanical Society Lecturer in Horticulture Initial salary according to qualifications and experience within the range £1 650 *to £1,950 per annum* Membership of F S S U and Children's Allowance Scheme The successful applicant will be responsible, under the direction of the George Harrison Professor of Botany, for the *control* of the University experimental grounds and for the instruction of working gardeners A genuine interest in, and knowledge of, practical horticulture, is essential, but applications *from appropriately qualified* physiologists, geneticists, etc, will be considered

Applications should be sent not later than October 19, 1962, to the Registrar, the University, *Manchester, 13, from whom* further particulars and forms of application may be obtained

UNIVERSITY OF MANCHESTER

Applications are invited for the post of Lecturer in Genetics in the Departments of Botany and Zoology in the Faculty of Science Candidates should have a wide interest in the subject so as to be able to lecture to students of both departments Duties to commence as soon as possible *Membership* of F S S U and Children's Allowance Scheme Salary on a scale £1,150 to £1,950 per annum, initial salary according to qualifications and experience

Applications should be sent not later than October 26, 1962, to the Registrar, the University, Manchester, 13, from whom further particulars and forms of application may be obtained

VICTORIA UNIVERSITY OF WELLINGTON

NEW ZEALAND

LECTURER IN BIOCHEMISTRY

Applications are invited for the above-mentioned post The salary will be £1,250 per annum, rising to £1,700 The initial salary will be determined *according to the qualifications* and experience of the appointee Approved fares to Wellington will be allowed for the appointee, his wife and his dependent children In addition, actual removal expenses will be allowed *within* specified limits

Further particulars and information as to the method of application should be obtained from the *Secretary, Association of Universities of the* British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S W 1 Applications close in New Zealand and London *on October 15, 1962*

PIUS XII COLLEGE, BASUTOLAND

DEPARTMENT OF BOTANY

This University College, which serves the High Commission Territories, invites applications for the post of *Lecturer in Botany*, the appointment to be taken up in either March or July, 1963

Applicants must have qualifications and interests in any of the following plant taxonomy, cytology, genetics, *field ecology*, and be able to teach courses, involving these subjects, to general degree students The post is open to honours graduates wishing to research in any of the above subjects

Present salary scale £1,000 by £50 to £1,550 Family allowances, pension scheme, free passage and baggage allowance for appointee, wife and children, house on campus

Further particulars, in the first instance, together with application forms from the Head of Department of Botany, University College of Pius XII, Roma, Basutoland, *before December* 1

NATIONAL INSTITUTE OF AGRICULTURAL BOTANY

Applications are *invited for the post* of Research Assistant to investigate the effects of storage conditions on the life span of crop seeds Applicants should hold an honours degree in botany or agricultural *botany* Starting salary £582 at age 21 rising to a maximum of £1,290 Superannuation scheme

Further particulars and application form from M G Tozer, Secretary, N I A B, *Huntingdon* Road, Cambridge Closing date October 15

CORROSION CHEMIST

Excellent career opportunity in Midwestern United States for electrochemist, chemist, or metallurgist with Ph D or B Sc degree Competence to plan and implement electrochemical research program oriented toward corrosion in petroleum production, transportation, and refining industry required. Work in new modern laboratory for company which pioneered in corrosion prevention in petroleum industry

PHOTOGRAPHIC EMULSION CHEMISTS

3M COMPANY

MINNESOTA MINING AND MANUFACTURING COMPANY

urgently require experienced

PHOTOGRAPHIC EMULSION CHEMISTS AND TECHNOLOGISTS for employment in the United States

Permanent positions are available both in Research and Development in laboratories situated in St Paul, Minnesota, and New York State, and salaries paid will be commensurate with experience Those engaged, together with their families, will be transferred to the United States at Company expense.

The 3M Company is well-known as one of America's most successful and progressive manufacturers of a wide range of products which are manufactured on a world-wide basis It is also recognized for its forward looking research policy and spends more than $25,000,000 each year in its laboratories

Applications, giving details of age, qualifications and experience, which will be treated in strictest confidence, should be made in writing to

DR. J. D. KENDALL, MANAGING DIRECTOR,
MINNESOTA 3M RESEARCH LIMITED,
3M HOUSE, WIGMORE STREET, LONDON, W.1, ENGLAND

RESEARCH SCIENTIST

for the

FOOD INDUSTRY

£1,100 to £1,500

A leading manufacturer in the food industry, rapidly expanding its output and diversifying its product range, wishes to engage an additional RESEARCH SCIENTIST to assist in the research work currently being carried out by the company's Research Division based in the Greater London area The successful candidate will have the opportunity of working on a wide range of problems connected with food research Previous industrial experience, although helpful, is not essential

Candidates, aged 22 to 27, should have a First-class or Top Second Honours Degree in Chemistry, and preference will be given to those who have specialized in biochemistry or physical chemistry

The starting salary will be in the range £1,100 to £1,500 per annum, with prospects of further advancement in due course

In addition, the company operates a generous non-contributory scheme covering pension, life assurance, and sick pay Assistance with housing can be made available

Please write to Box No 657, T. G. Scott and Son, Ltd, 1 Clement's Inn, London, W.C 2.
